Vulpia octoflora (Walter) Rydb. var. *octoflora* [= *Festuca octoflora* Walter]; *Brooks s.n.*, Lowe (1921)

POTAMOGETONACEAE

Potamogeton diversifolius Raf., lakes/ponds/impoundments (littoral–rooted-floating); *Channell s.n.* (MISSA), Jones (1974a), *McDaniel pers. obs.* (specimen extant)

Potamogeton nodosus Poir., IF, lakes/ponds/impoundments (littoral -rooted-floating), C(I); *Bruza 983*

SMILACACEAE

Smilax bona-nox L., BP, PR, IF, bottomland hardwood forests, mesophytic upland hardwood forests, prairie cedar woodlands, chalk outcrops, O/C; *Easley s.n.* (MISSA), *Leidolf s.n.*,

Leidolf and McDaniel (1998), Lowe (1921), Morris et al. (1993), *Ray 100* (MISSA), *6749* (MISSA), Theriot et al. (1993), *Tracy s.n.* (MISSA)

Smilax glauca Walter, IF, bottomland hardwood forests, pine-mixed hardwood forests, C; Lowe (1921), *Ray 6781* (MISSA), Theriot et al. (1993)

Smilax lasioneura Hook., BP, PR, mesophytic upland hardwood forests, xeric upland hardwood forests, C; *Easley s.n.* (MISSA), *Morris 3092*, *Persons s.n.* (MISSA), *Ray 6722* (MISSA), *8059* (MISSA)

Smilax pulverulenta Michx., PR, mesophytic upland hardwood forests, O; *220*, *Easley s.n.* (MISSA), Lowe (1921), *McDaniel 28154*, Morris et al. (1993)

Smilax rotundifolia L., BP, PR, IF, bottomland hardwood forests, pine forests, pine-mixed hardwood forests, prairies, C; *232*, *1320*, *Askew 62*, *68*, Leidolf and McDaniel (1998), Lowe (1921), *McDaniel 1676*, *31028*, Morris et al. (1993), *Price s.n.* (MISSA), Theriot et al. (1993)

Smilax smallii Morong, IF, bottomland hardwood forests; *Leidolf s.n.*, Theriot et al. (1993)

Smilax tamnoides L., BP, IF, bottomland nardwood forests; *Ray 100* (MISSA), Theriot et al. (1993)

TRILLIACEAE

Trillium cuneatum Raf., IF, bottomland hardwood forests; *Blocker s.n.* (MISSA)

Trillium recurvatum L.C. Beck, PR, IF, bottomland hardwood forests, mesophytic upland hardwood forests, R/C; *96*, *149 (R96)*, *1261 (R96)*, *Channell s.n.* (MISSA), *Easley s.n.* (MISSA), *Fletcher s.n.* (MISSA), Morris et al. (1993), *Persons s.n.* (MISSA), *Smith 1935*

TYPHACEAE

**Typha angustifolia* L., BP, canals/drainage ditches (emergent), A(I); *McDaniel 31081*

Typha latifolia L., BP, IF, canals/drainage ditches (emergent), A(I); *315*, *603*, *1569*

XYRIDACEAE

Xyris torta Small, IF, pine forests, canals/drainage ditches (emergent), seepage areas, R/U; *480*, *525*, *1558*, *McDaniel 2640*, *Smith 1443*

ZANNICHELLIACEAE

Zannichellia palustris L., IF, lakes/ponds/impoundments (littoral–submergent); Jones (1974a), *Ray s.n.* (MISSA)

ACKNOWLEDGMENTS

We gratefully acknowledge the MNHP for funding part of the field work for this study through a 1994 Wildlife Heritage Research Grant. Appreciation is also extended to John R. MacDonald and Randy C. Warren for their assistance with field work. Mary E. Barkworth and Charles T. Bryson generously offered their expertise in the identification of Poaceae and Cyperaceae, respectively. Use of the facilities at UTC was crucial in the final stages of preparation of this manuscript, and is hereby gratefully acknowledged. Finally, we would like to thank Mary E. Barkworth, Scott C. Barras, C.T. Bryson, Barney Lipscomb, and J.R. MacDonald for providing helpful comments on earlier versions of the manuscript, as well as three anonymous referees for review of the final draft.

Book Review

Richard Dwight Porcher and Douglas Alan Rayner. 2001. **A Guide to the Wildflowers of South Carolina.** (ISBN 1-57003-437-0, hbk.). University of South Carolina, 718 Devine Street, Columbia, SC 29208, U.S.A. (Orders: 800-768-2500, 800-768-0740 fax). $49.95, 551 pp, 11 figures, numerous color photos, 7" × 10 1/4".

This book is near the top of the 'must-have' list for anyone interested in plants and plant communities of the eastern United States. The range of subject matter is far broader than implied by the title—so much so that one has to wonder at the title selection. The wildflower photos and brief accompanying descriptions (about 700 species) occupy a little more than half of the 551 total pages—the remainder provides a wealth of information on aspects of botany and plant communities in South Carolina. The book could easily serve as the primary basis for courses in plant taxonomy, plant communities, or related topics, especially as supplemented by "Natural Vegetation of South Carolina" (J.M. Barry 1980) and "Wildflowers of the Carolina Low Country and Lower Pee Dee" (Porcher 1995).

With this nearly unmitigated commendation in introduction, an outline of the chapters conveys a quick overview:

- Introduction
- Natural History of Selected Groups of Vascular Plants (including carnivorous plants, native orchids, poisonous plants, woody vines, epiphytic, saprophytic, and parasitic plants, medicinal plants and folk remedies, edible wild plants, naturalized plants, and duckweeds)
- History of Field Botany in South Carolina
- Selected Topics on Natural History and Ecology (including 'Succession in Natural Communities,' Fire in the South Carolina Landscape, Carolina Bays of the Coastal Plain, 'Reproductive Strategies of Vascular Plants,' 'Economic and Cultural Notes,' 'Longleaf Pine and the Naval Stores Industry,' 'Agriculture and Forestry: Effects on South Carolina's Physical Landscape,' and 'Marshes, Swamps, Peatlands, Bogs, and Fens'
- South Carolina's Natural Wildflower Communities (The Mountains, The Piedmont, The Fall-Line Sandhills, The Coastal Plain, The Maritime Strand; numerous subdivisions in each category)
- Species Descriptions and Color Plates (divided into the same 'natural communities' and numerous subdivivisions to match the preceding chapter, with the addition of 'The Ruderal Communities')
- Field Guide to Natural Plant Communities (also divided first by community type, then by county – then, for those wanting to walk through the real thing, various natural area preserves, State Parks, and National Forests are identified and discussed under individual counties)
- Indices and other "end" pieces (including keys to selected plant groups, a guide to South Carolina herbaria, references, common and scientific names, and a "general index")

I register only a single objection—if one is trying to match a plant in hand with a photo in the book, an inordinate amount of page-flipping may be required. The photographs and brief notes on individual species are arranged first by community and then by some other criterion that is not clear to me. Even within one community, species of a single family are not grouped together. This objection, however, must show a personal bias of mine, because other recent books (including the earlier S.C. volume by Porcher, noted above) are published with the same format, the much-experienced authors (Porcher & Rayner) explicitly intend the book to be a field guide, and apparently inexperienced students find the arrangement useful.—*Guy L. Nesom, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX, 76102-4060, U.S.A.*

ABSTRACT

We studied the relationship between West Gulf Coastal Plain plant endemics and habitat. Approximately half of all West Gulf Coastal Plain endemics are associates of one habitat: xeric sandylands. We discuss some implications of these data to age and former extent of xeric sandylands in the region, notably isolation of the West Gulf Coastal Plain from the East Gulf Coastal Plain and a long and distinctive biotic history.

KEY WORDS: West Gulf Coastal Plain, endemic plants, grossarenic dry uplands, xeric sandylands.

RESUMEN

Se han estudiado las relaciones entre las plantas endémicas y el hábitat de la llanura costera del Golfo Oeste. Aproximadamente la mitad de los endemismo están asociados a un hábitat: terrenos arenosos xéricos. Se discuten algunas implicaciones de estos datos con la edad y extensión anterior de los terrenos arenosos xéricos en la región, notablemente aislamiento de la llanura costera del Golfo Oeste de la llanura costera del Golfo Este y una historia biótica larga y diferente.

INTRODUCTION

The Atlantic and Gulf Coastal plains have been recognized as a floristic province of distinction in part due to the high number of endemic and near-endemic species (Takhtajan 1986). In North America, the Atlantic and Gulf Coastal floristic province is second only to the California floristic province in endemics; approximately 27 percent of its native species are endemic or near endemic to it while in the latter province 48% are endemic or near endemic (Sorrie & Weakley 2001). While important local centers of endemism, such as the Apalachicola and Lake Wales regions of Florida, are well known, the significance of the West Gulf Coastal Plain (WGCP) has received almost no attention in the published literature or has been portrayed as largely depauperate in

endemics (Ricketts et al. 1999). That the WGCP constitutes a regional center of endemism has been only recently demonstrated (Estill & Cruzan 2001; Sorrie & Weakley 2001). In this paper, based on a list of endemics from the WGCP and their habitat affiliation, we begin a dialogue about evolutionary origin, divergence, and migration for the region.

The WGCP center of endemism encompasses most of eastern Texas and western Louisiana, southern Arkansas, and southeastern Oklahoma (Fig. 1). Its western margin is not clearly defined, either geologically or botanically (Fennemen 1938; Christensen 2000). Its eastern boundary is the Mississippi River floodplain. Our definition is approximately the same as that of Sorrie and Weakley (2001) except that we encompass slightly more of south-central Texas because the east Texas flora clearly extends into those counties just east of Austin and San Antonio (Region 3 of Hatch et al. 1990). Although within the geological coastal plain, the gulf prairies and marshes (Region 2 of Hatch et al. 1990) are excluded because it appears that this region is a separate center of endemism (Sorrie & Weakley 2001), which itself needs detailed study.

METHODS

To develop a list of endemics, we obtained species distributional data from a wide variety of sources, including regional, state and local floras, floristic atlases, published papers, and monographs (among which are Correll & Johnston 1970; Jones 1977; MacRoberts 1984, 1989; Poole & Riskind 1987; Smith 1988; Bridges & Orzell 1989; Taylor & Taylor 1989; Hatch et al. 1990; Isely 1990; Nixon & Kell 1993; Texas Organization for Endangered Species 1993; Thomas & Allen 1993–1998; Walker 1993; Texas Natural Heritage Program 1995a; Turner 1996; Nesom 1997; Diggs et al. 1999; Kartesz & Meacham 1999; Louisiana Natural Heritage Program 1999; Turner in press; and several web sites centering on the Flora of Texas Consortium), Natural Heritage Program databases, our own field work, and an examination of herbarium specimens, notably at ASTC, BRIT, Corpus Christi Museum of Science and History, GH, LSU, LSUS, NCU, NLU, SBSC, SHST, TAMU (on line), TEX, VDB, and WWF. The list was begun independently of Sorrie and Weakley (2001) and has continued to develop after their list appeared.

We consider those species to be endemic whose occurrence is limited to the WGCP; near-endemic refers to species that are at least 90 percent centered on the WGCP. These species are listed in Appendix 1.

We encountered two major problems in developing the list. First, distributional information is incomplete in many cases. Various state and regional distribution maps and descriptions are either incomplete or do not agree. Second, taxonomic difficulties are frequent: for example, should *Trillium texanum* Buckley be considered a species, a subspecies, or a distinct taxon at all? We simply have followed the predominant view where possible (e.g., Jones et al. 1997;

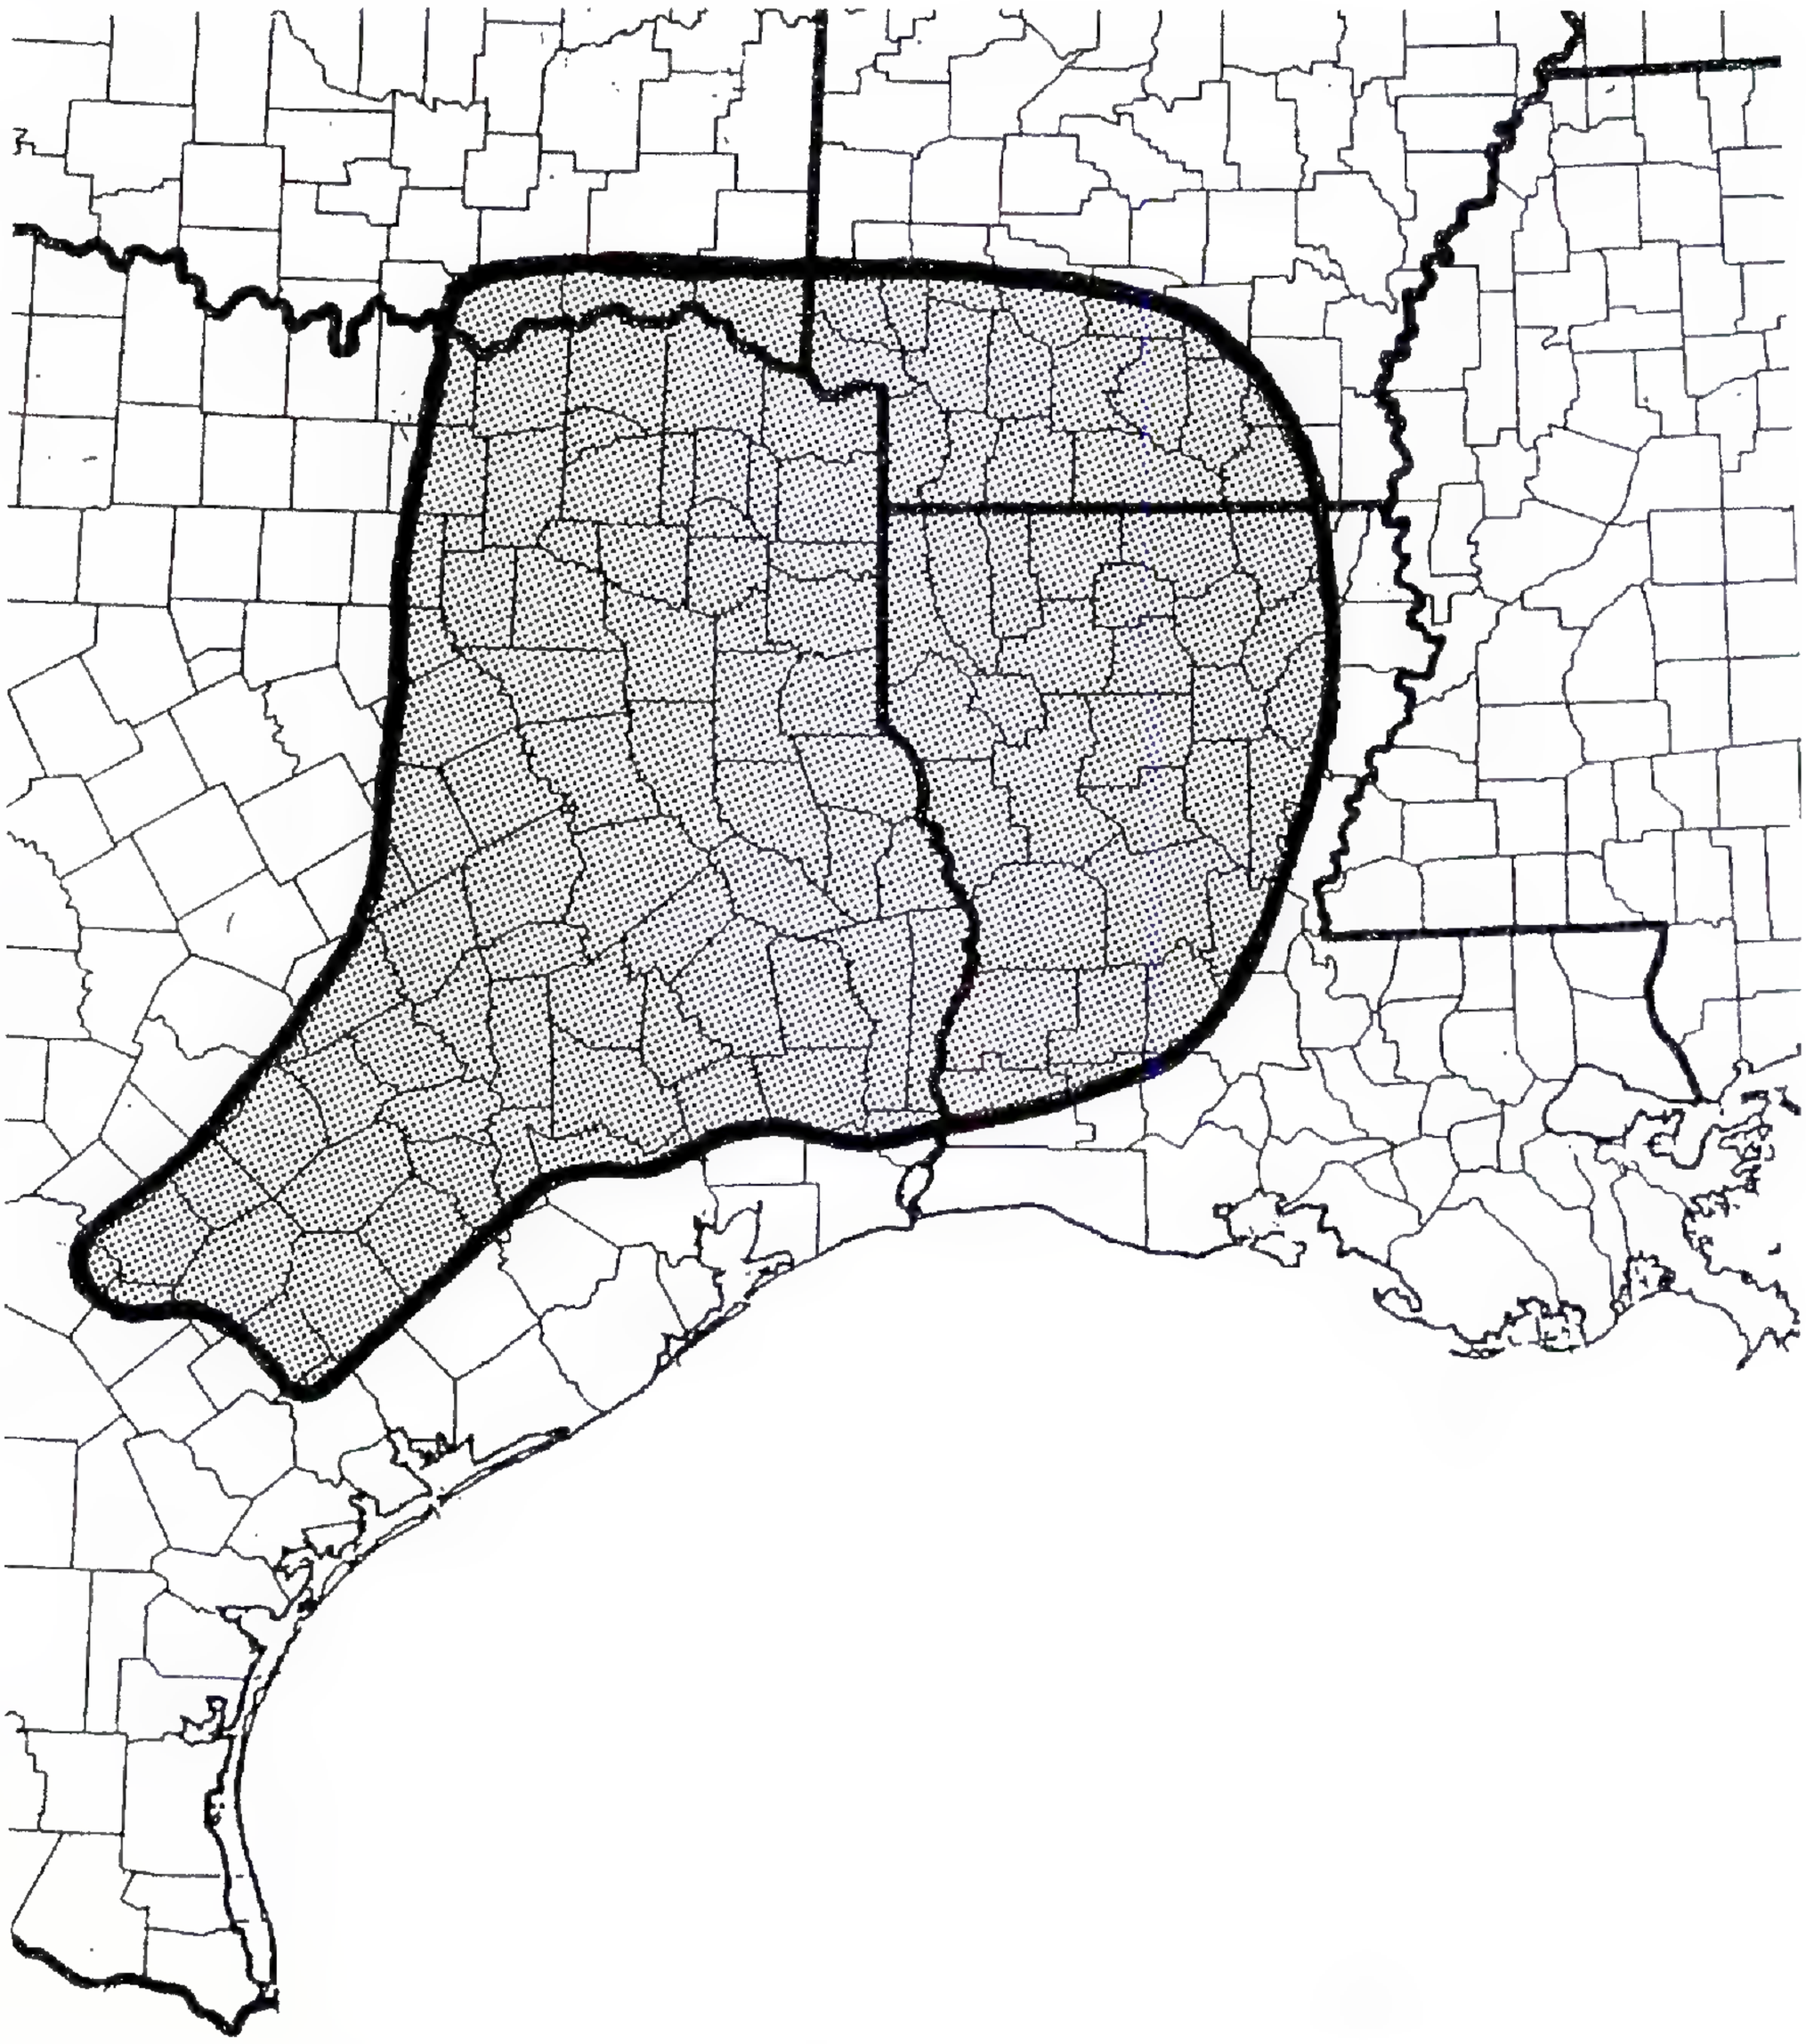

FIG. 1. Map showing West Gulf Coastal Plain.

Kartesz & Meacham 1999). We have developed a fairly conservative list, which we will continue to update and refine in future.

After we had developed the endemic/near-endemic list (which, for the sake of brevity, will be referred to hereafter as "endemics"), we attempted to determine for each taxon its community association (habitat) in the WGCP. We examined all major classifications (Diamond et al. 1987; Texas Organization for Endangered Species 1992; Harcombe et al. 1993; Foti et al. 1994; Texas Natural Heritage Program 1995b; Louisiana Natural Heritage Program 1998; Turner et.

al. 1999; Van Kley 1999a, 1999b; Weakley et al. 1999; Hoagland et al. 2000). We selected the Turner et al. (1999; see also Van Kley 1999a, 1999b) classification because it is based on quantitative data and is manageable and applicable over a wide geographic area. With a few modifications, it is presented in Appendix 2 with associated plant group in parentheses and with The Nature Conservancy (TNC) "ecological group" designations in brackets (Weakley et al. 1999). We then assigned each endemic to habitat of best fit on the basis of the literature, personal experience, and herbarium labels. It was not always possible to determine community type, a few taxa were assigned to two types, and a few were left blank.

RESULTS

Table 1 presents number and percent of WGCP endemics associated with each community. Of the 96 taxa in our endemic list, we were able to classify all but three to one or more communities. Number 1, xeric sandylands, proved to have by far the most endemics. Of the 96 endemics, 53 percent are associated with xeric sandylands. The communities with the next highest number of endemics are barrens, glades and weches, and bogs and wet pine savannas, each with nine percent of the total.

TABLE 1. Plant communities and number and percent of WGCP endemics associated with each.

Community	Number	Percent
1 Xeric sandylands	51	53
2 Upland pine savanna, mixed woods	4	4
3 Loamy dry-mesic uplands	0	0
4 Bogs, wet pine savannas	9	9
5 Calcareous forest	0.5	1
6 Mayhaw pond	2	2
7 Barrens, glades, weches barrens	9	9
8 Beech slopes	1	1
9 Stream course	1.5	2
10 Baygall	3.5	4
11 Bottomland, floodplain	6	6
12 Ponds, marshes	0	0
13 Prairies	5.5	6
Unknown	3	3
Total	**96**	**100**

DISCUSSION

Xeric sandylands have the most endemics, a fact recognized by Bridges and Orzell (1987, 1989) some years ago. Of the three genera endemic to the WGCP, *Maclura*, *Brazoria*, and *Rhododon*, two, *Brazoria* and *Rhododon*, are associated with xeric sandylands (Turner 1995, 1996). Xeric sandylands are open to sparsely

wooded areas that typically occur on terraces or ridges composed of deep sand, generally of marine Tertiary origin (McBryde 1933; Bridges & Orzell 1989; Harcombe et al. 1993; MacRoberts & MacRoberts 1994, 1995, 1996; MacRoberts et al. 2002; Turner et al. 1999). Water and air move rapidly through these soils. Soils, where undisturbed, are often cryptogamic. Foliose lichens (*Cladonia* spp.) may be common. Stunted *Quercus stellata* Wangenh., *Q. margarettiae* Ashe ex Small, *Q. incana* W. Bartram, and various *Carya* species are dominant trees in xeric sandylands. Other characteristic species are *Bulbostylis ciliatifolia* (Elliott) Fernald, *Cnidoscolus texanus* (Muell.-Arg.) Small, *Croton argyranthemus* Michx., *Cyperus grayioides* Mohlenbrock, *Eriogonum longifolium* Nutt., *E. multiflorum* Benth., *Froelichia floridana* (Nutt.) Moq., *Hymenopappus artemisiifolius* DC., *Matelea cynanchoides* (Engelm.) Woodson, *Mirabilis albida* (Walter) Heimrl, *Opuntia humifusa* (Raf.) Raf., *Paronychia drummondii* Torr. & A. Gray, *Pediomelum digitatum* (Nutt. ex Torr. & A. Gray) Isely, *P. hypogaeum* (Nutt. ex Torr. & A. Gray) Rydb. var. *subulatum* (Bush) J.W. Grimes, *Phlox drummondii* Hook., *Polygonella americana* (Fisch. & C.A. Mey.) Small, *P. polygama* (Vent.) Engelm. & A. Gray, *Selaginella arenicola* Underwood subsp. *riddellii* (Van Eselt.) R.M. Tryon, *Streptanthes hyacinthoides* Hook., *Talinum rugospermum* Holz., *Tetragonotheca ludoviciana* (Torr. & A. Gray) A. Gray ex Hall, *Thelesperma filifolium* (Hook.) A. Gray, *Tradescantia reverchonii* Bush, *Tragia* spp., *Yucca louisianensis* Trel., and *Zornia bracteata* J.F. Gmel.

Sorrie and Weakley (2001) identify the Carrizo Sands of Texas as one endemic center for the Atlantic and Gulf Coastal plains (see McBryde 1933 for a description of this area). While the Carrizo Formation is a narrow band running from the Rio Grande to northeastern Texas and then southward to eastern Texas and has xeric sandylands scattered throughout, xeric sandylands are not confined to this formation but occur virtually throughout the WGCP in both pineywoods and post oak savanna in Oklahoma, Arkansas, Louisiana, and Texas as shown by the distribution of species fidel to this community as discussed by MacRoberts et al. (2002). In that study, in order to develop an objective idea of the distribution of xeric sandylands, we chose 42 fidel species from the total list of species occurring in this community and mapped these by county and parish over their ranges (Fig. 2) (see also McBryde 1933; Drawe et al. 1978; Ajilvsgi 1979; Marietta & Nixon 1983; Matos & Rudolph 1985; Bridges & Orzell 1989; Ward & Nixon 1992; Harcombe et al. 1993; MacRoberts & MacRoberts 1994, 1995, 1996; Hoagland 2000).

While widespread, xeric sandylands are not a dominant community across the WGCP but are generally found in relatively small patches. At the time of European settlement it has been estimated that xeric sandylands accounted for less than one percent of western Louisiana (Louisiana Natural Heritage Program 1993) and, although there are no published figures, probably no more than this in either Oklahoma or Arkansas. In Texas, especially along the Carrizo for-

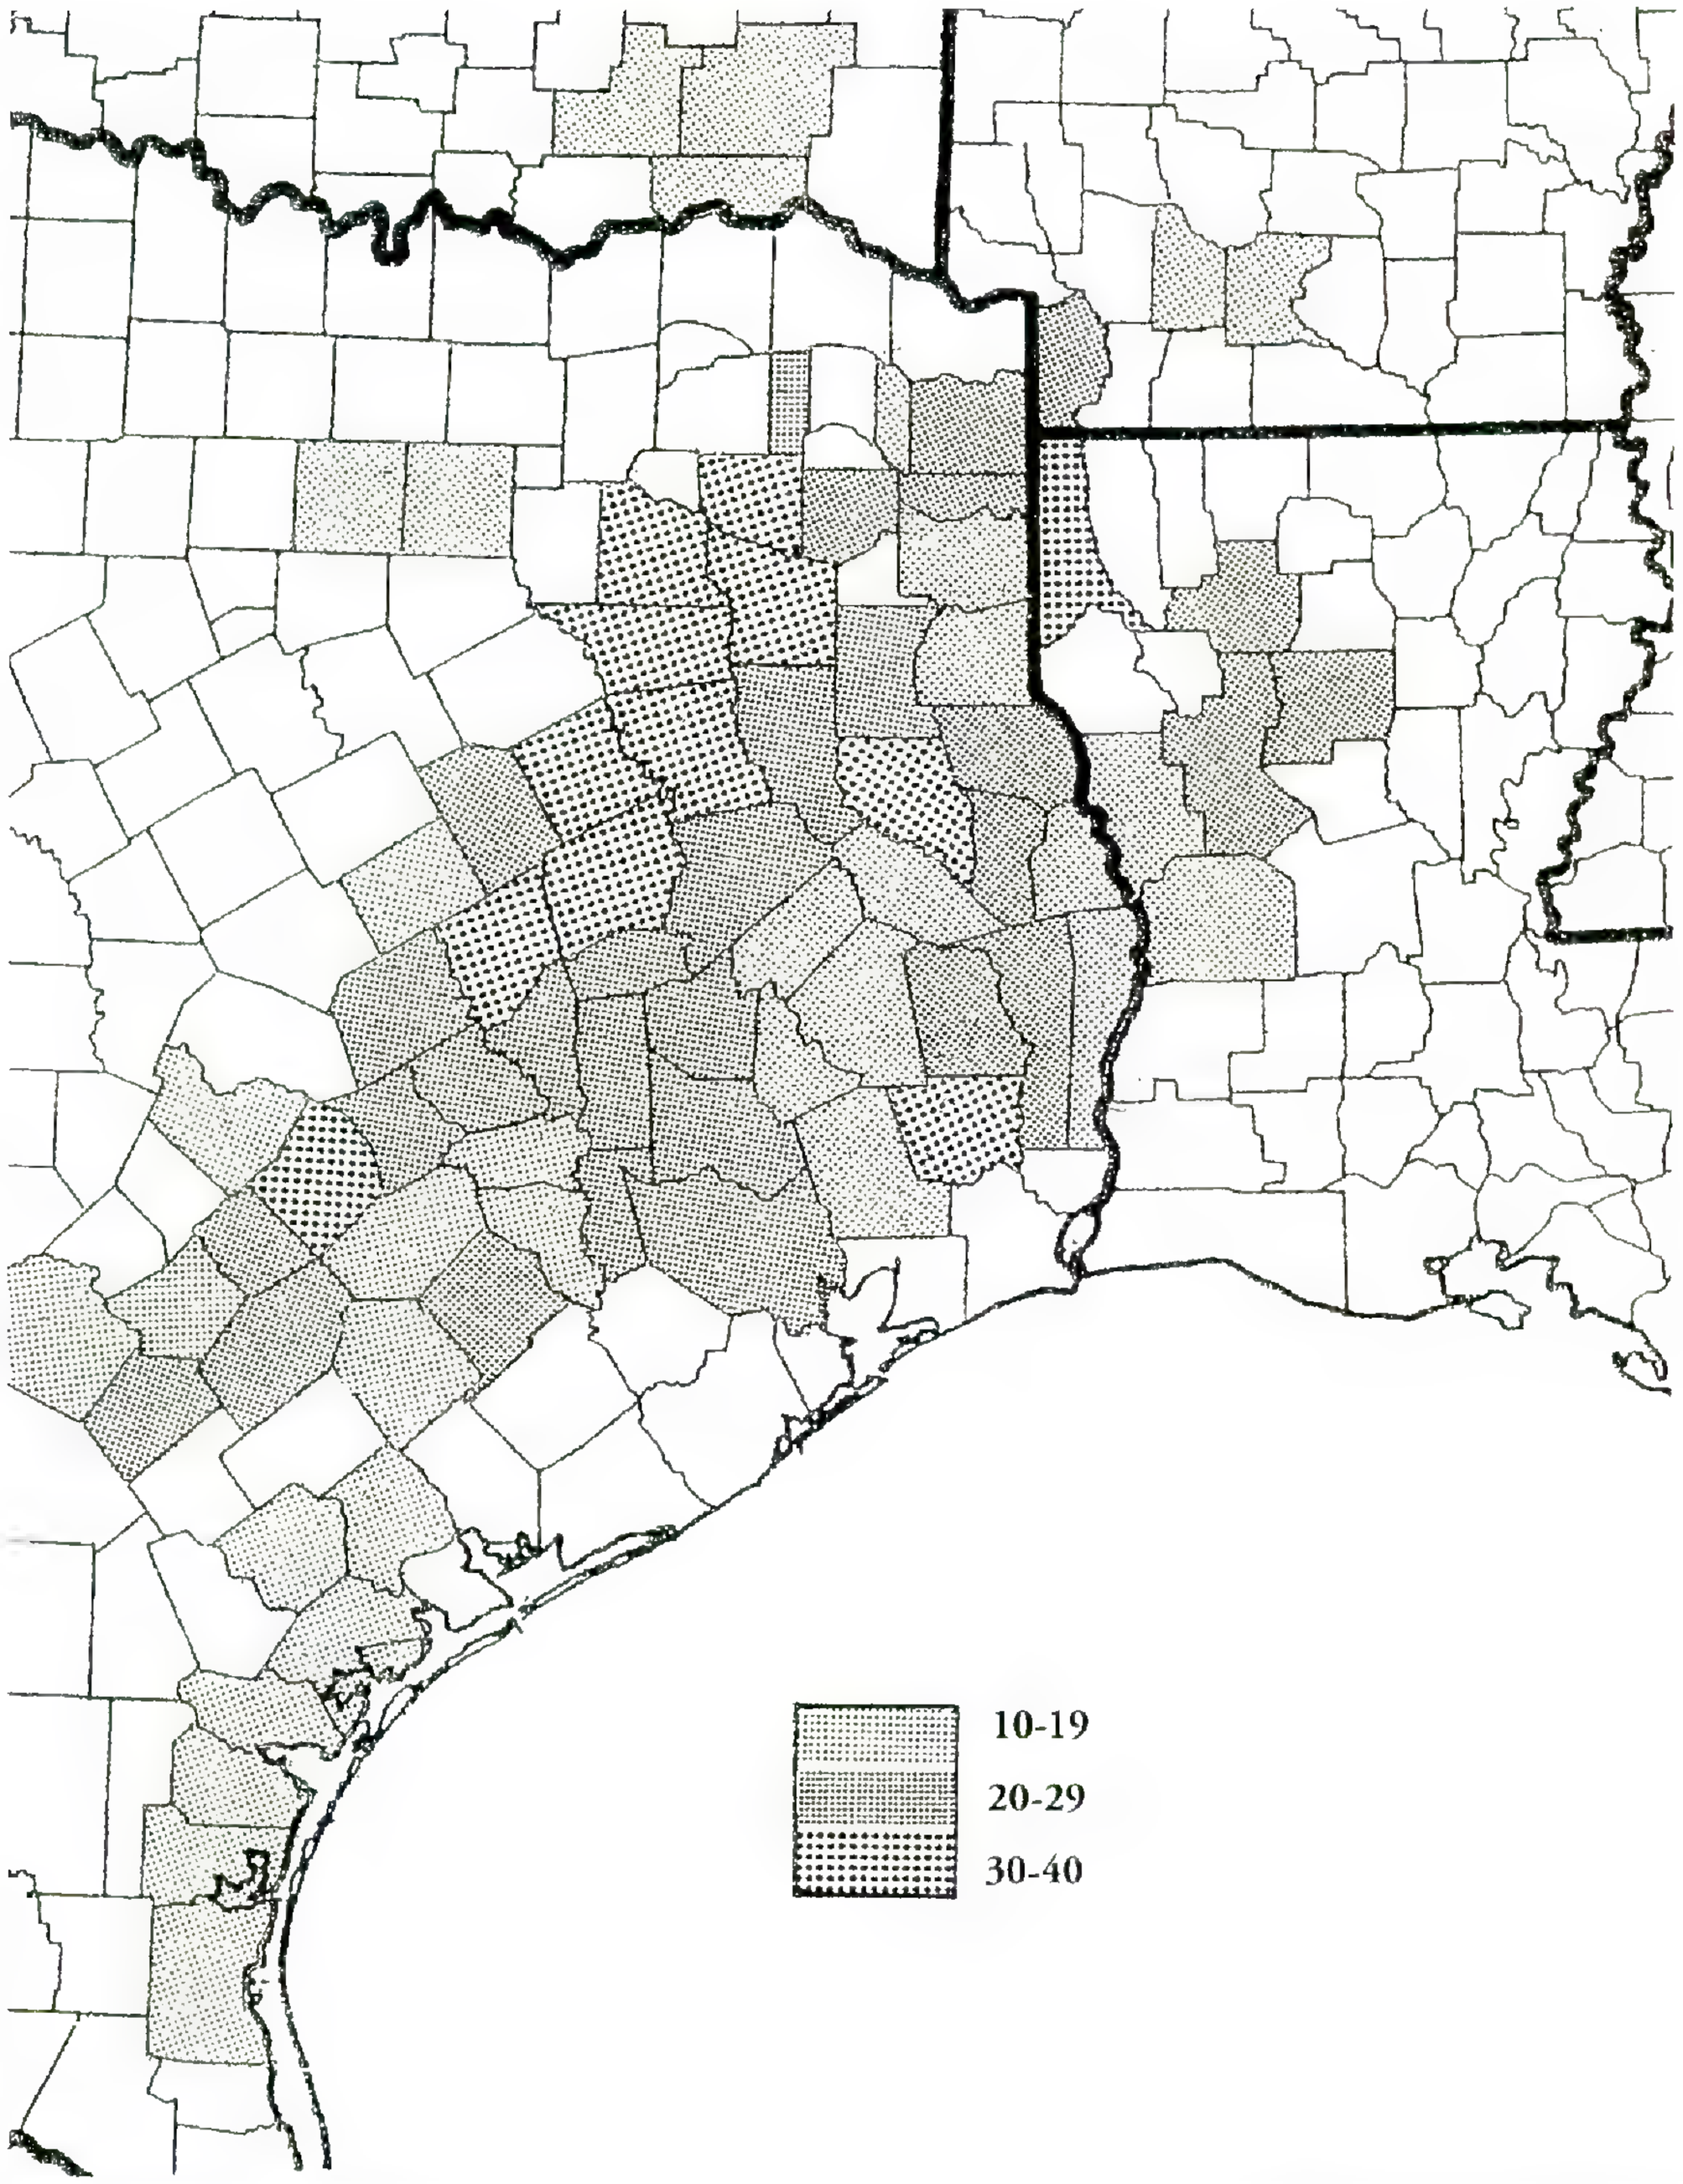

FIG. 2. Xeric sandyland species distribution. Key = number of species in sample list of 42 species located in each county either by personal inspection, herbarium searches, or literature (see MacRoberts et al. 2002 for further explanation).

mation (McBryde 1933), xeric sandylands were common, but for the whole of the region this community is unlikely to have amounted to more than five percent of the area.

While there appears to be disagreement among palynologists concerning

short-term climatic events in the southeast in general and the WGCP in particular during glacial and post-glacial times as to whether or not there were south Texas and Mexican refugia (Martin & Harrell 1957; Ellis et al. 1995; Schmidtling & Hipkins 1998), the major long-term patterns are relatively clear (Bryant 1977; Watts 1980; Bryant & Holloway 1985; Webb 1988; Webb et al. 1993; Delcourt et al. 1993; Delcourt & Delcourt 1993, 2000; Bousman 1998). The picture that emerges supports the thesis presented here: xeric sandylands (open post-oak savannas and woodlands on sandy soils) were present as a community type within the WGCP since the last glaciation. We know that coarse sands necessary for the physical development of xeric habitats were present since the Eocene (McBryde 1933; Sorrie & Weakley 2001 and references therein). Prone to frequent water deficits and nutrient limitations, these soils undoubtedly have always dramatically affected vegetation structure and composition, which probably explains why percent sand present in surface soils of the Coastal Plain is a key determinant of vegetation patterns throughout this area (McBryde 1933; Harcombe et al. 1993; Peet & Allard 1993; Christensen 2000). We also know from pollen counts from dozens of bogs along the western edge of the WGCP (unfortunately the only area of east Texas with lengthy pollen records) that oaks and grasses dominated after the last glaciation (Bryant 1977; Bryant & Holloway 1985; Holloway et al. 1987). The prehistoric landscape that is revealed is one that is not dissimilar to that seen in the region today: oak-dominated sandy "savannas" and hilltops that act as reservoirs for water that feeds the adjacent seeps, marshes, streams, and peat bogs of the area (McBryde 1993; MacRoberts & MacRoberts 1998, MacRoberts et al. 2002). Unfortunately, palynology is seldom precise to species; our hypothesis would be that oaks were probably those of dryer habitat: *Quercus stellata* and *Q. incana*, and that the herbaceous vegetation included, in part, the evolving endemics described here. After all, the peat bog habitats that contain the continuous pollen profiles extending back thousands of years still exist (see MacRoberts & MacRoberts 1998; Potzger & Tharp 1947; Graham & Heimsch 1960; Bryant 1977; Holloway et al. 1987 for pollen analyses of east-central Texas bogs).

Additionally, the Mississippi River/Embayment has been a migration barrier since the Eocene (Rock 1957; Blair 1958; Sorrie & Weakley 2001). Many of the similarities between east and west have come about in the last 6000 years as the climates have approximated one another. Sandylands of the WGCP retain a distinctive flora rich in endemic and near-endemic taxa, which express more clearly than other communities in the region a long and distinctive phylogenetic history. The flora of many WGCP xeric sandylands has been enriched by the addition of taxa more widespread in the Coastal Plain. In contrast, xeric sandylands along the western drier boundary of the WGCP appear to retain a greater percentage of taxa locally characteristic of the region and with a relatively longer affiliation with it (McBryde 1933).

Our data on endemism coupled with palynological and climatic data strongly suggest that communities analogous, if not homologous, to xeric sandylands may have been a significant component of the WGCP since the last glaciation and perhaps earlier. Open oak-hickory woodlands and savannas with a rich herbaceous layer and many openings may have been the characteristic landscape over broad areas; perhaps moving south during glacial advances and north again with their retreat.

We suggest that the WGCP should no longer be overlooked as a distinct and critical region of endemism within the Coastal Plain. It may be more meaningful to look upon it as a dynamic entity with an independent and, to a certain extent, isolated ecological and biological history.

APPENDIX 1

Endemics (E) and near-endemics (NE) of the West Gulf Coastal Plain. Nomenclature follows Kartesz and Meacham (1999) in most cases. Community (habitat) types in brackets (see Appendix 2).

AGAVACEAE

Yucca louisianensis Trel., (E) [1]

ALISMATACEAE

Sagittaria papillosa Buchenau, (NE) [6]

APIACEAE

Eryngium hookeri Walp., (NE) [9 & 13]

ASTERACEAE

Berlandiera pumila (Michx.) Nutt. var. *scabrella* G.L. Nesom & B.L. Turner, (E) [1]
Chrysopsis texana Nesom, (E) [1]
Coreopsis intermedia Sherff, (E) [1]
Echinacea sanguinea Nutt., (E) [1]
Evax candida (Torr. & A. Gray) A. Gray, (NE) [1]
Gaillardia aestivalis (Walter) H. Rock var. *winkleri* (Cory) B.L. Turner, (E) [1]
Helenium drummondii H. Rock, (E) [4]
Helianthus debilis Nutt. ssp. *silvestris* Heiser, (E) [1]
Helianthus occidentalis Riddell ssp. *plantagineus* (Torr. & A. Gray) Shinners, (NE) [1]
Hymenopappus artemisiifolius DC., (NE) [1]
Hymenopappus carrizoanus B.L. Turner, (NE) [1]
Krigia wrightii (A. Gray) K.L. Chambers ex K.J. Kim, (NE) [ ]
Lactuca hirsuta Muhl. ex Nutt. var. *albiflora* (Torr. & A. Gray) Shinners, (NE) [1]
Liatris cymosa (H. Ness) K. Schumann, (E) [7]
Liatris tenuis Shinners, (E) [2]
Oligoneuron nitidum (Torr. & A. Gray) Small, (NE) [7]
Palafoxia hookeriana Torr. & A. Gray, (E) [1]
Palafoxia reverchonii (Bush) Cory, (E) [1]
Rudbeckia maxima Nutt., (NE) [13]
Rudbeckia scabrifolia L.E. Brown, (E) [10]
Rudbeckia texana (Perdue) P.Cox & Urbatsch, (NE) [4]
Solidago ludoviciana (A. Gray) Small, (NE) [1]
Symphyotrichum puniceum (L.) A. & D. Love var. *scabricaule* (Shinners) G.L. Nesom, (E) [4]
Tetragonotheca ludoviciana (Torr. & A. Gray) A. Gray ex Hall, (E) [1]
Thelesperma flavodiscum (Shinners) B.L. Turner, (E) [1]
Vernonia texana (A. Gray) Small, (NE) [1]

BRASSICACEAE

Leavenworthia aurea Torr. var. *texana* (Mahler) Rollins, (E) [7]
Lesquerella angustifolia (Nutt. ex Torr. & A. Gray) S. Watson, (E) [7]
Lesquerella pallida (Torr. & A. Gray) S. Watson, (E) [7]

CAMPANULACEAE

Lobelia puberula Michx. var. *pauciflora* Bush, (NE) [4]

CAPPARACEAE

Polanisia erosa (Nutt.) H.H. Iltis, (E) [1]

CARYOPHYLLACEAE

Paronychia drummondii Torr. & A. Gray, (E) [1]

Paronychia setacea Torr. & A. Gray, (NE) [1]
Silene subciliata B.L. Robins, (E) [2]

COMMELINACEAE
Tradescantia reverchonii Bush, (NE) [1]
Tradescantia subacaulis Bush, (E) [1]

CUSCUTACEAE
Cuscuta gronovii Willd. ex J.A. Schultes var. *calyptrata* Engelm., (E) [11]

CYPERACEAE
Fuirena bushii Kral, (NE) [4]
Rhynchospora glomerata (L.) Vahl. var. *angusta* Gale, (NE) [4,10]

EUPHORBIACEAE
Euphorbia bicolor Engelm. & A. Gray, (NE) [13]

FABACEAE
Amorpha paniculata Torr. & A. Gray, (E) [4]
Astragalus distortus Torr. & A. Gray var. *engelmannii* (E. Sheld.) M.E. Jones, (E) [1]
Astragalus leptocarpus Torr. & A. Gray, (NE) [1]
Astragalus soxmaniorum Lundell, (E) [1]
Baptisia bracteata Muhl. ex Elliott var. *laevicaulis* (A. Gray ex W. Canby) Isely, (NE) [2,13]
Baptisia nuttalliana Small, (NE) [1]
Dalea phleoides (Torr. & A. Gray) Shinners var. *phleoides*, (NE) [1]
Dalea villosa (Nutt.) Spreng var. *grisea* (Torr. & A. Gray) Barneby, (E) [1]
Mimosa hystricina (Small) B.L. Turner, (NE) [1]
Pediomelum hypogaeum (Nutt. ex Torr. & A. Gray) Rydb. var. *subulatum* (Bush) J.W. Grimes, (NE) [1]
Trifolium amphianthum Torr. & A. Gray, (NE) [2,13]
Trifolium bejariense Moric., (E) [1]

GENTIANACEAE
Bartonia texana Correll, (E) [10]

HYDROPHYLLACEAE
Nemophila phacelioides Nutt., (NE) [9]
Phacelia glabra Nutt., (NE) [13]

IRIDACEAE
Iris hexagona Walter var. *flexicaulis* (Small) R. Foster, (NE) [6]
Sisyrinchium sagittiferum Bicknell, (E) [4]

LAMIACEAE
Brazoria truncata (Benth.) Engelm. & A. Gray var. *pulcherrima* (Lundell) M.W. Turner, (E) [1]
Brazoria truncata (Benth.) Engelm. & A. Gray var. *truncata*, (NE) [1]
Monarda lindheimeri Engelm. & A. Gray ex A. Gray, (E) [5,13]
Monarda viridissima Correll, (E) [1]
Physostegia digitalis Small, (E) [2]
Physostegia longisepala Cantino, (E) [4,13]
Physostegia pulchella Lundell, (NE) [11]
Rhododon ciliatus (Benth.) Epling, (E) [1]
Scutellaria cardiophylla Engelm. & A. Gray, (E) [1]

LILIACEAE
Trillium gracile J.D. Freeman, (E) [8]
Trillium texanum Buckley, (E) [10]

MALVACEAE
Hibiscus dasycalyx Blake & Shiller, (E) [11]

MORACEAE
Maclura pomifera (Raf.) C.K. Schneid., (E) [11]

NYCTAGINACEAE
Abronia macrocarpa L. Galloway, (E) [1]

ONAGRACEAE
Oenothera heterophylla Spach ssp. *heterophylla*, (NE) [1]

ORCHIDACEAE
Spiranthes parksii Correll, (E) [7]

PAPAVERACEAE
Argemone albiflora Hornem. ssp. *texana* G.B. Ownbey, (NE) [1]

POACEAE
Panicum brachyanthum Steud., (NE) [4]
Sporobolus silveanus Swallen, (E) [7]

POLEMONIACEAE
Phlox cuspidata Scheele, (NE) [ ]
Phlox drummondii Hook. var. *drummondii*, (NE) [1]
Phlox nivalis Lodd. ex Sweet ssp. *texensis* Lundell, (E) [1]

POLYGONACEAE
Eriogonum longifolium Nutt. var. *plantaginium* Engelm. & A. Gray, (E) [1]
Eriogonum multiflorum Benth., (NE) [1]
Polygonella parksii Cory, (E) [1]

RANUNCULACEAE
Delphinium carolinianum Walter ssp. *vimineum* (D. Don) M.J. Warnock, (NE) [1]
Thalictrum arkansanum Boivin, (NE) [11]
Thalictrum texanum (A. Gray) Small, (E) [11]

ROSACEAE
Crataegus nananixonii Phipps & R.O'Kennon, (E) [1]

Crataegus warneri Sarg., (E) [1]

SCROPHULARIACEAE

Agalinis caddoensis Pennell, (E) [ ]

Agalinis navasotensis M. Dubrule & J. Canne-Hilliker, (E) [7]

Gratiola flava Leavenw., (NE) [7]

Penstemon murrayanus Hook., (NE) [1]

SOLANACEAE

Physalis mollis Nutt.var. *variovestita* (Waterfall) Sullivan, (NE) [1]

VALERIANACEAE

Valerianella florifera Shinners, (NE) [1]

APPENDIX 2

Community classification of West Gulf Coastal Plain (from Turner et al. 1999; The Nature Conservancy [TNC] designations in brackets [Weakley et al. 1999]).

1. Xeric sandylands. Grossarenic dry uplands (*Tragia* group). As a modification of this type we emphasize the xeric conditions, notably areas referred to as xeric sandylands and Post Oak-Blue Jack Oak Savanna.[TNC 305 and 320 in part].
2. Upland pine savanna, mixed woodlands. Arenic dry upland (*Schizachyrium* group). [TNC 305 and 307 in part].
3. Loamy dry-mesic uplands (*Schizachyrium*, *Callicarpa*, and *Chasmanthium* groups). We modify this entry to exclude communities where *Drosera* group (see below) dominates and place them with the next entry. [TNC 307 in part].
4. Bogs, wet pine savannas. Sandy/loamy wet herbaceous seeps and wetland pine savannas (*Drosera* group). [TNC 330 and 347].
5. Calcareous forest. Clayey dry mesic upland (*Chasmanthium* group). [TNC 375 in part].
6. Mayhaw pond. Clayey wet upland depression (*Justicia* group). [TNC 340].
7. Barrens, glades, and weches barrens (*Bigelowia*, *Callirhoe*, *Dalea* groups). Open, herb-dominated areas on bedrock exposures. [TNC 350].
8. Beech slopes. Mesic lower slopes and terraces (*Callicarpa* and *Mitchella* groups). [TNC 308].
9. Stream course. Loamy mesic stream bottom (*Mitchella* and *Arisaema* groups) and loamy wet-mesic stream bottoms (*Bignonia* and *Justicia* groups). [TNC 365 in part]
10. Baygall. Loamy wet forested seeps (*Osmunda* group). [TNC 360].
11. Floodplain, bottomland hardwood/river bottom communities; includes swamps (*Callicarpa*, *Bignonia*, *Justicia*, and *Ceratophyllum* groups). This combines Turner et al.(1999) community types 12–15. [TNC 385].
12. Open ponds and emergent marshes (not in Turner et al. 1999). [TNC 345].
13. Prairies (not in Turner et al. 1999). [TNC 375 in part].

ACKNOWLEDGMENTS

Billie Turner, Jason Singhurst, Vaughn Bryant, the curators of all herbaria where we worked, and two anonymous reviewers are thanked for their help.

ABSTRACT

An annotated, vouchered checklist is provided of the vascular plant taxa of the 284 hectares Hickory Creek Unit of the Big Thicket National Preserve, Tyler County, in southeast Texas. The Hickory Creek Unit consists of four plant communities: wetland pine savanna, upland pine savanna, pond, and baygall. Four hundred one taxa are documented and their community affiliations are given. Previous lists for this unit numbered over 500 taxa. We believe that the discrepancy is the result of the larger lists being, in part, "conceptual" (what could be there, not what was actually there).

KEY WORDS: Big Thicket National Preserve, floristics, Hickory Creek Unit, Texas

RESUMEN

Se ofrece un catalogo anotado, con pliegos testigo de los taxa de plantas vasculares de las 284 hectareas de la Hickory Creek Unit de la Big Thicket National Preserve, Condado de Tyler, en el sureste de Texas. La Hickory Creek Unit consiste en cuatro comunidades vegetales: sabana húmeda de pinos, sabana en tierras altas de pinos, estanque, y matorral de Ilex coriacea. Se documentan cuatrocientos un taxa y se da la filiación a su comunidad. Los listados previos de esta unidad contenían más de 500 taxa. Creemos que la discrepancia es el resultado de que las grandes listas fueron en parte "conceptuales" (lo que puede estar allí, no lo que está actualmente allí).

INTRODUCTION

The Big Thicket region of southeast Texas has been characterized as floristically rich (Gunter 1971; Eisner 1973; Ajilvsgi 1979; Watson 1979, 1986; Peacock 1994; Official Guide 1997), a characterization that persists in spite of the fact that botanically the entire area is understudied and underdocumented. As yet, there is no vouchered and annotated plant list for the Big Thicket region, for the Big Thicket National Preserve, or for any of the twelve Big Thicket National Preserve units. The best plant lists from the entire area are the one for the Roy E. Larsen Sandylands Sanctuary, Hardin County (Matos & Rudolph 1985) and the one for the Little Thicket Nature Sanctuary, San Jacinto County (Peterson & Brown 1983). Even at the county level, the only vouchered lists are those of

Nesom and Brown (1998), which are considered by the authors to be "preliminary." All other plant lists for the Big Thicket region, beginning with Parks & Cory (1936) and continuing through Watson (1982), U.S. National Park Service (1993), and Yu (n.d.) are unannotated and are not based on vouchered specimens. Consequently there is no way to determine whether the lists represent what the author found or whether they represent what Cozine (1993) calls a "speculative checklist"; a conjectural compilation of what possibly might be there, not what is actually known to be there.

The purpose of this study was to begin a baseline floristic list for the Big Thicket region and the Big Thicket National Preserve by producing an annotated, vouchered checklist of the vascular flora for one unit of the Big Thicket National Preserve.

SITE AND METHODS

The Big Thicket is located mostly within the longleaf pine region of the West Gulf Coastal Plain in southeast Texas (Parks & Cory 1936; McLeod 1971; Harcombe & Marks 1979; Marks & Harcombe 1981; Harcombe et al. 1993). The Big Thicket National Preserve consists of 12 units scattered over seven Texas counties. The units range from 222 hectares to 10,100 hectares and total about 34,000 hectares (Peacock 1994). The unit we selected for a floristic inventory is the 284 hectare Hickory Creek Unit, located in southern Tyler County (Fig. 1). The Hickory Creek Unit, which consists of four plant communities (pond, wetland pine savanna, upland pine savanna, baygall), was chosen for inclusion in the Big Thicket National Preserve because of its pine savannas (see Ajilvsgi [1979]; Watson [1979], Harcombe & Marks [1981]; and MacRoberts & MacRoberts [1998] for descriptions of these communities). The natural characteristic of the unit was relatively flat open "grasslands" with scattered longleaf pines. The unit has little relief and ranges from 35 meters to 42 meters elevation. Aerial photographs show the unit still partly open in 1974 when the Big Thicket National Preserve acquired it, but most openings have subsequently been invaded by shrubs and offsite pines due largely to fire suppression and dormant-season prescription burns (Streng & Harcombe 1982; McClung 1988; Bridges & Orzell 1989; MacRoberts & MacRoberts 2000). Details regarding edaphic and climatic factors of the Hickory Creek Unit can be found in Deshotels (1978), Watson (1979), Marks and Harcombe (1981), and Streng and Harcombe (1982). A map of the unit is in Harcombe and Marks (1979) and in Streng and Harcombe (1982).

Like all the units of the Big Thicket National Preserve, the Hickory Creek Unit has not been the subject of a floristic inventory although extensive but desultory collecting and floristic sampling has occurred there (Streng 1979; Streng & Harcombe 1982; Watson 1982). Nonetheless, the Hickory Creek Unit is perhaps the best collected unit of the Big Thicket National Preserve. Streng (1979 and Streng & Harcombe 1982) conducted a study of factors affecting tree

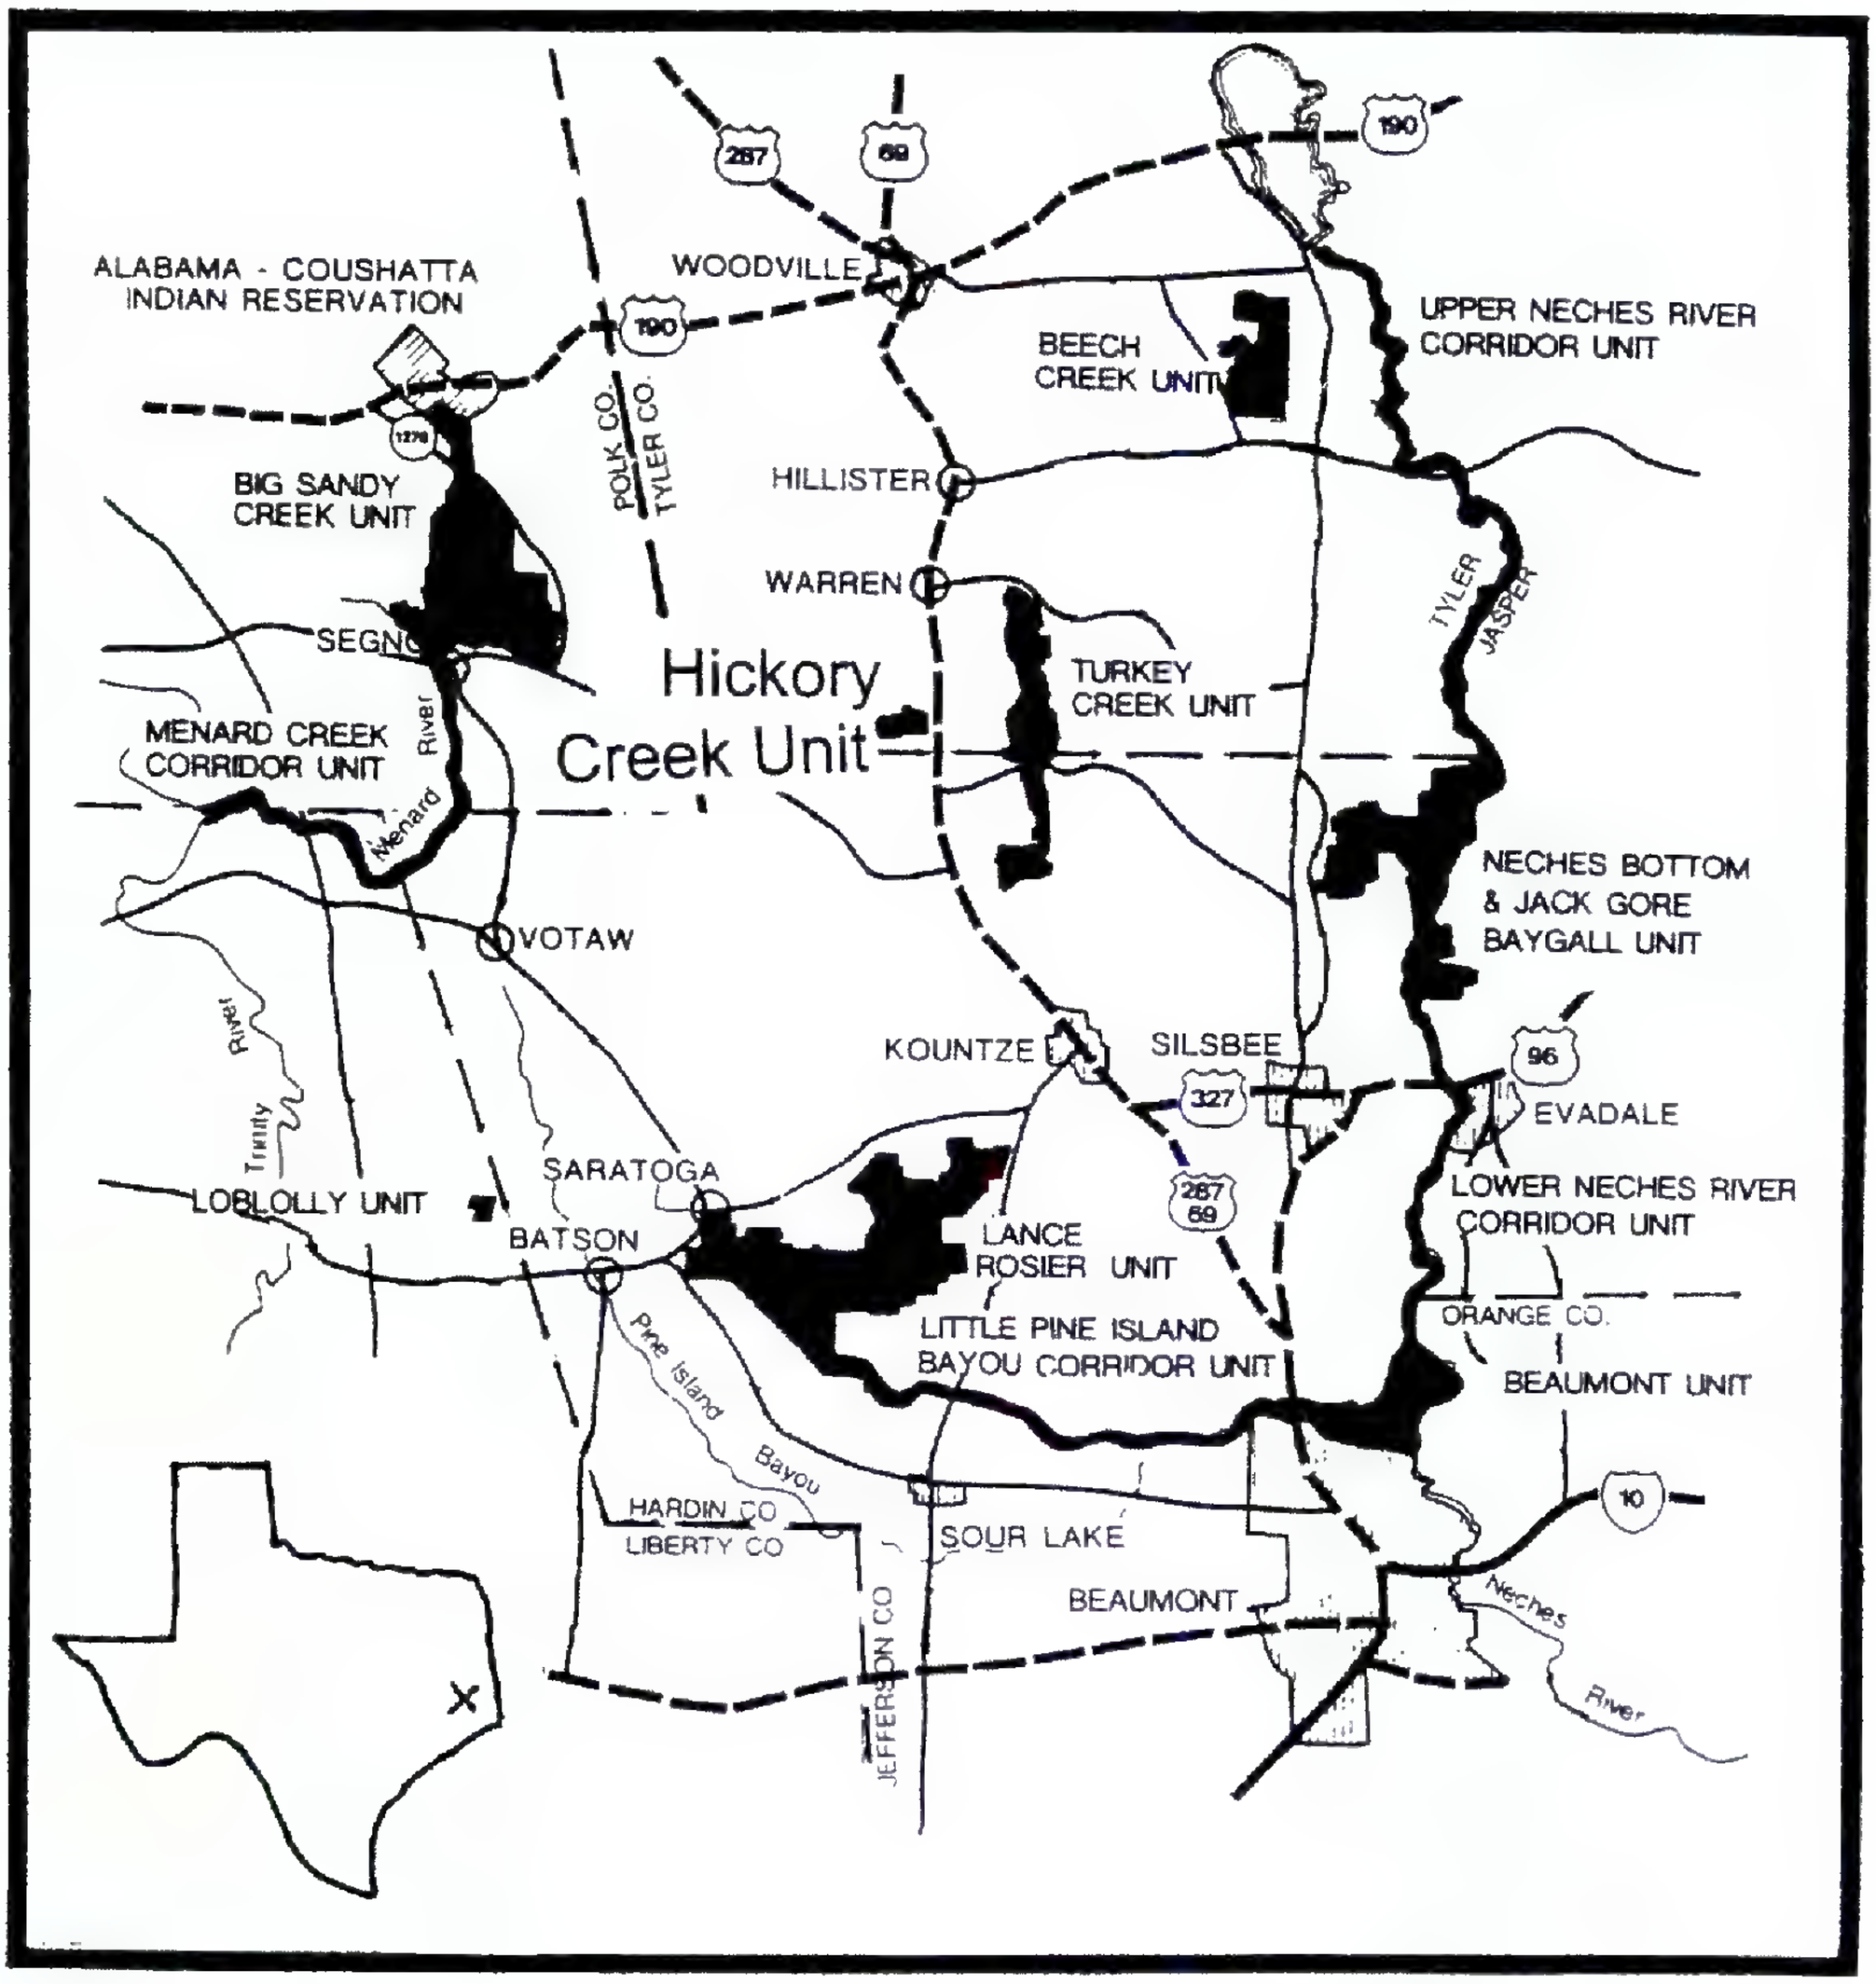

Fig. 1. Location of Hickory Creek Unit within the Big Thicket National Preserve, Texas.

density in the Hickory Creek Unit in the late 1970s and made extensive plant collections. Geraldine Watson, former botanist with the Big Thicket National Preserve, also collected there in the 1970s and 1980s. Their plant specimens have been housed largely at Rice and Lamar universities along with a few collections by Paul Harcombe, Peter Marks, and C. Liu. These collections number about 300 sheets. There are also a few collections housed at SHST and SBSC.

The MacRoberts' collected 430 specimens from the Hickory Creek Unit during 13 field trips beginning 7 March 2000 and ending 13 September 2001. Larry Brown collected about 179 specimens from the unit during four field trips between 27 April and 5 October 2001 (he had previously collected about 30 specimens between 1979 and 1997).

Since our purpose is to produce a list of taxa known to occur on the Hickory Creek Unit, a vouchered specimen was considered to be the only evidence acceptable for inclusion in the list. In all, about 950 herbarium specimens form the data for this report.

Rejected are three previous lists: Watson (1982) produced a list of about 530 taxa for the Hickory Creek Unit, the U.S. National Park Service (1993) produced a list of about 1200 taxa for the entire Big Thicket National Preserve, and Yu (n.d.) produced a list of 525 taxa, excluding trees, for the Hickory Creek Unit. The Yu and National Park Service lists are based largely on the Watson list. Aside from being unannotated and not vouchered, inclusion criteria are not explained for any of these lists. Also, all three lists were found to have extensive misidentifications and dubious entries (Brown & Brown 1996; Brown n.d.).

Nomenclature follows Kartesz (1994), Jones et al. (1997), and Kartesz and Meacham (1999) in most cases.

The following abbreviations are used:

CL = C. Liu. His specimens are at Rice University.

DS = Donna Streng. Her collections are unnumbered and are at Rice University.

GW = Geraldine Watson. Unless otherwise indicated, her National Park Service specimens are at Rice University.

LB = Larry Brown. Unless otherwise indicated, his specimens are at SBSC.

McL = C.A. McLeod. His collections are unnumbered and are at SHST.

MM – Barbara R. and Michael H. MacRoberts. Except where noted, their collections are temporarily at Rice University.

MW = Michael Warnock. His specimens are at SHST.

PH = Paul Harcombe. His specimens are at Rice University.

PM = Peter Marks. His collections are at Rice University.

* = exotic

+ = see note at end of list.

The MacRoberts, Streng, Watson, Harcombe, Marks, and Liu specimens have been annotated by Larry Brown (Brown & Brown 1996; Brown n.d.). Barbara MacRoberts and Justin Williams examined the specimens of McLeod and Warnock at SHST. Where we had more than one voucher, up to four have been listed (see annotated list under results).

In addition to the taxa listed, we designate the plant community or communities with which we found each species most closely associated. Community abbreviations are given below and are put in parentheses (see Ajilvsgi [1979] for additional description of these communities).

(U) = Upland pine savanna (aka Longleaf-Bluestem Uplands).

(W) = Wetland pine savanna (aka Longleaf-Blackgum Savannas).

(B) = Baygall/Stream course. A small part of this is Sweetgum-Oak Floodplain and Palmetto-Oak Flats.

(P) = Ephemeral pond. (These shallow ponds, which may become dry in drought years, but hold water longer than other areas, have not been adequately described on the Big Thicket.)

RESULTS

Annotated list of the vascular plants found in the Hickory Creek Unit taxa.

Notes:
Cuscuta sp. The specimen had no flowers or fruit.
Gymnopogon brevifolius. This is the third record for this species in Texas.
Lobelia reverchonii. We prefer to keep this a good species.
Sarracenia alata. This species was introduced to the Hickory Creek Unit by Geraldine Watson in the early 1970's. It occurs naturally in wetland pine savannas nearby.
Scleria baldwinii. This is the first pineywoods region record.

DISCUSSION

Our plant list numbers 401 taxa (385 native) for the Hickory Creek Unit. Previous plant lists (Watson 1982; Yu n.d.) numbered well over 500 taxa. Why the discrepancy? Three possibilities suggest themselves: 1) our list is only about 75 percent complete, 2) the Unit was much richer 25 years ago when the first lists were developed, and 3) previous lists are at least partly conjectural, being "padded" with taxa that could possibly be there but which have not actually been found there.

These possibilities are not mutually exclusive and, at the present time, it is impossible to fully assess them. However, some comments are apropos.

Before we began collecting, the documented plant list for the Hickory Creek Unit numbered about 190 taxa (Brown n.d.). We doubled the list in 17 field trips in 2000 and 2001. If the total number of taxa at Hickory Creek numbered 530—i.e., only about one third had previously been documented—one would expect that, at least at first, approximately two out of every three of our collections would have been an addition. This was not the case, and we actively avoided recollecting in many cases. Additionally, on the basis of the specimens collected from the Hickory Creek Unit in the 1970's and 1980's and reported by Watson (1982), there is no evidence that there then existed plant communities additional to those that occur there now that would account for the additional taxa. The same taxa collected by Streng and Watson in the 1970's were recollected in 2000–2001, and Watson's listed species do not signal other communities. Finally, aerial photographs, scientific literature, historical accounts, and reminiscences by "old timers" clearly do not place additional plant communities there. With only four communities represented, one would expect on the basis of typical community counts (75 to 125 taxa per community type with some overlap among communities) only 400 taxa. Consequently, while we have obviously not found every taxon that exists at the Hickory Creek Unit, we feel that our list of 401 taxa is over 90 percent complete.

There is some evidence to support the second hypothesis. The Hickory Creek Unit is severely fire suppressed and has lost much of its herbaceous layer (Streng & Harcombe 1982; McClung 1988; MacRoberts & MacRoberts 2000). Today there remain only small patches of the extensive pine savannas that were

previously there. Some taxa undoubtedly could have been lost or at least become very rare in the ensuing years. For example, we did not find several of the conspicuous orchids that had been collected in the 1970's. Nonetheless, it is unlikely that 125 taxa have been lost in that period.

The third hypothesis probably explains a good deal of the discrepancy. The Parks and Cory (1936) Big Thicket plant list was partly conjectural ("could possibly be there") (Cozine 1993) and there is no reason to suppose that the Watson (1982) list was not also partly conjectural. Many species on Watson's (1982) list do not occur in the area and were probably added either because of misidentification (both in the field and of herbarium specimens) or because of conjecture. Cases in point include *Eriocaulon koernickianum* Van Heurck & Muell.-Arg. (undoubtedly misidentified *Lachnocaulon anceps*) and *E. septangulare* With. (probably misidentified *E. decangulare*) (see Brown & Brown 1996).

Thus, while it is the case that our list is incomplete and that a few taxa may have been lost, most taxa that have grown in the Hickory Creek Unit during the past quarter century have been collected (probably 90+ percent). We believe that the Hickory Creek Unit has about 400 to 425 native taxa, far fewer than have been attributed to it.

ACKNOWLEDGMENTS

This study was supported in part by a Southwest Parks and Monuments Association Grant # 99-2: "Distribution of bogs and wetland pine savannas." Roy Zipp, U.S. Park Service, aided with the work. Brooke Wheeler, Paul Harcombe, and Sandi Elsik provided information about several specimens at Rice University. Monique Reed provided information about a specimen at TAMU. Justin Williams provided information about four specimens at SHST. Thanks to Jason Singhurst and Walter Holmes for their comments on the manuscript.

BOOKS RECEIVED/NOTICES

Annotations and comments by Editor

Horticulture/Gardening

MAGNUS JOHNSON. 2001. **The Genus Clematis. Edited and Translated by Bengt Sundström.** (ISBN 91-631-1030-X, hbk.). Magnus Johnson Plantskola AB and Bengt Sundström, Bränningestrandsvägen 63, 151 39 SÖDERTÄLJE, Sweden. (Orders: 08-550 979 77; +468 550 970 77). $110.00, 896 pp, 24 gouaches, about 100 illustrations from classical literature and ink drawings by the author, about 170 color photos, 6 3/4" × 9 1/2".

This book is quite the summary of *Clematis*. It represents 60 years of knowledge as a botanist, landscape architect and nurseyman (Magnus Johnson) of clematis. The first part (**Clematis: a stimulant in the garden**) deals with history, horticultural aspects, and the cultivation and propagation of clematis. The second part (**Scientific description of Clematis**) covers scientific descriptions of clematis including many new names and new combinations. The third part addresses **Descriptions of sections species and cultivars.** If you grow or want to grow clematis then you will want this book.

PETER F. YEO. 2002. **Hardy Geraniums. Second Edition.** (ISBN 0-88192-541-1, hbk.). Timber Press, Inc., 133 S.W. Second Avenue, Suite 450, Portland, OR 97204-3527, U.S.A. (Orders: www.timberpress.com, 800-327-5680, 503-227-2878, 503-227-3070 fax). $34.95, 218 pp, 57 color photos, 151 line illustrations, 7 3/8" × 9 3/4".

From the Preface: "The expression 'hardy geraniums' is the favoured one in horticultural circles for distinguishing *Geranium* of the botanists from *Pelargonium*, and it therefore forms the title of this book." *Geranium* it is and nearly all *Geranium* species have some ornamental value according to the author. This is a comprehensive guide and one that is beautifully illustrated with fantastic color pictures. The b/w line drawings are exceptionally nice. Whether you are a botanist or geranium enthusiast you can't go wrong with this book

FR. JOHN L. FIALA. 1988 (paper back edition 2002). **Lilacs: The Genus Syringa.** (ISBN 0-88192-530-6, pbk.). Timber Press, Inc., 133 S.W. Second Avenue, Suite 450, Portland, OR 97204-3527, U.S.A. (Orders: www.timberpress.com, 800-327-5680, 503-227-2878, 503-227-3070 fax). $34.95, 372 pp, 395 color illustrations, 82 b/w photos, 22 line drawings, 3 charts, 1 bn/w photo, 2 keys, 1 map, 8 1/2" × 11".

A classic now in paper back. You can almost smell the lilac fragrance.

VASCULAR PLANTS OF THE MAPIMÍ BIOSPHERE RESERVE, MÉXICO: A CHECKLIST

Abel García-Arévalo

Instituto de Ecología A.C.
Centro Regional Durango
Apdo. Postal 632
Durango, Dgo. 34000, MÉXICO

ABSTRACT

The Mapimí Biosphere Reserve is located at the boundaries of the Mexican states of Chihuahua, Coahuila, and Durango in the part central of the Chihuahuan Desert. It extends over 342,387 ha. within an endorreic basin locally known as the Bolsón de Mapimí. Elevation varies between 1000 and 1480 m. Weather is very arid mostly with summer rains, the average annual precipitation is 264 mm. Vegetation types are mostly xerophytic scrub and halophytic grassland.

The vascular flora is composed of approximately 71 families, 242 genera, 403 species and 426 taxa approximately. Families with the greatest diversity are Asteraceae, Poaceae, Cactaceae, and Fabaceae. Genera with the greatest number of species are *Sporobolus*, *Opuntia*, *Aristida*, and *Acacia*. I recorded 31 species endemic to the Chihuahuan Desert.

RESUMEN

La Reserva de la Biosfera de Mapimí, se ubica en el límite de unión de los estados de Chihuahua, Coahuila y Durango en la parte central del Desierto Chihuahuense, conforma una extensión aproximada de 342,387 ha y constituye una cuenca endorreica, denominada Bolsón de Mapimí. La altitud varía entre los 1000 y 1480 m, su clima es muy árido con lluvias en verano y la precipitación es de aproximadamente 264 mm anuales. Los tipos de vegetación se clasifican como matorral xerófilo y pastizal halófilo.

La flora está constituida de aproximadamente 71 familias, 242 géneros, 403 especies y 426 taxa. Las familias con mayor diversidad son Asteraceae, Poaceae, Cactaceae y Fabaceae. Los géneros *Sporobolus*, *Opuntia*, *Aristida* y *Acacia* son los que presentan el mayor número de especies. Se registran 31 especies endémicas al Desierto Chihuahuense.

INTRODUCTION

The Mapimí Biosphere Reserve is representative of the arid ecosystems of the Chihuahuan Desert (Martínez & Morello 1977; Halffter 1981). Geographically it is located at the boundaries of the Mexican states of Chihuahua, Coahuila, and Durango (Bartolino 1988), between 26º 29' and 26º 52' N latitude, and 103º 32' and 103º 58' W longitude (Fig. 1). It has an area of 342,387 ha and constitutes an endorreic basin where fresh water sediments, basalts, and rhyolites have accumulated until the Miocene. The Mapimí Biosphere Reserve is part of the Bolsón de Mapimí, and it includes the basins of Laguna de Patos, Laguna de Palomas, and part of Laguna del Rey. It is part of the Mapimí subprovince.

The climate is very arid with most rain falling mostly between July and

SIDA 20(2): 797–807. 2002

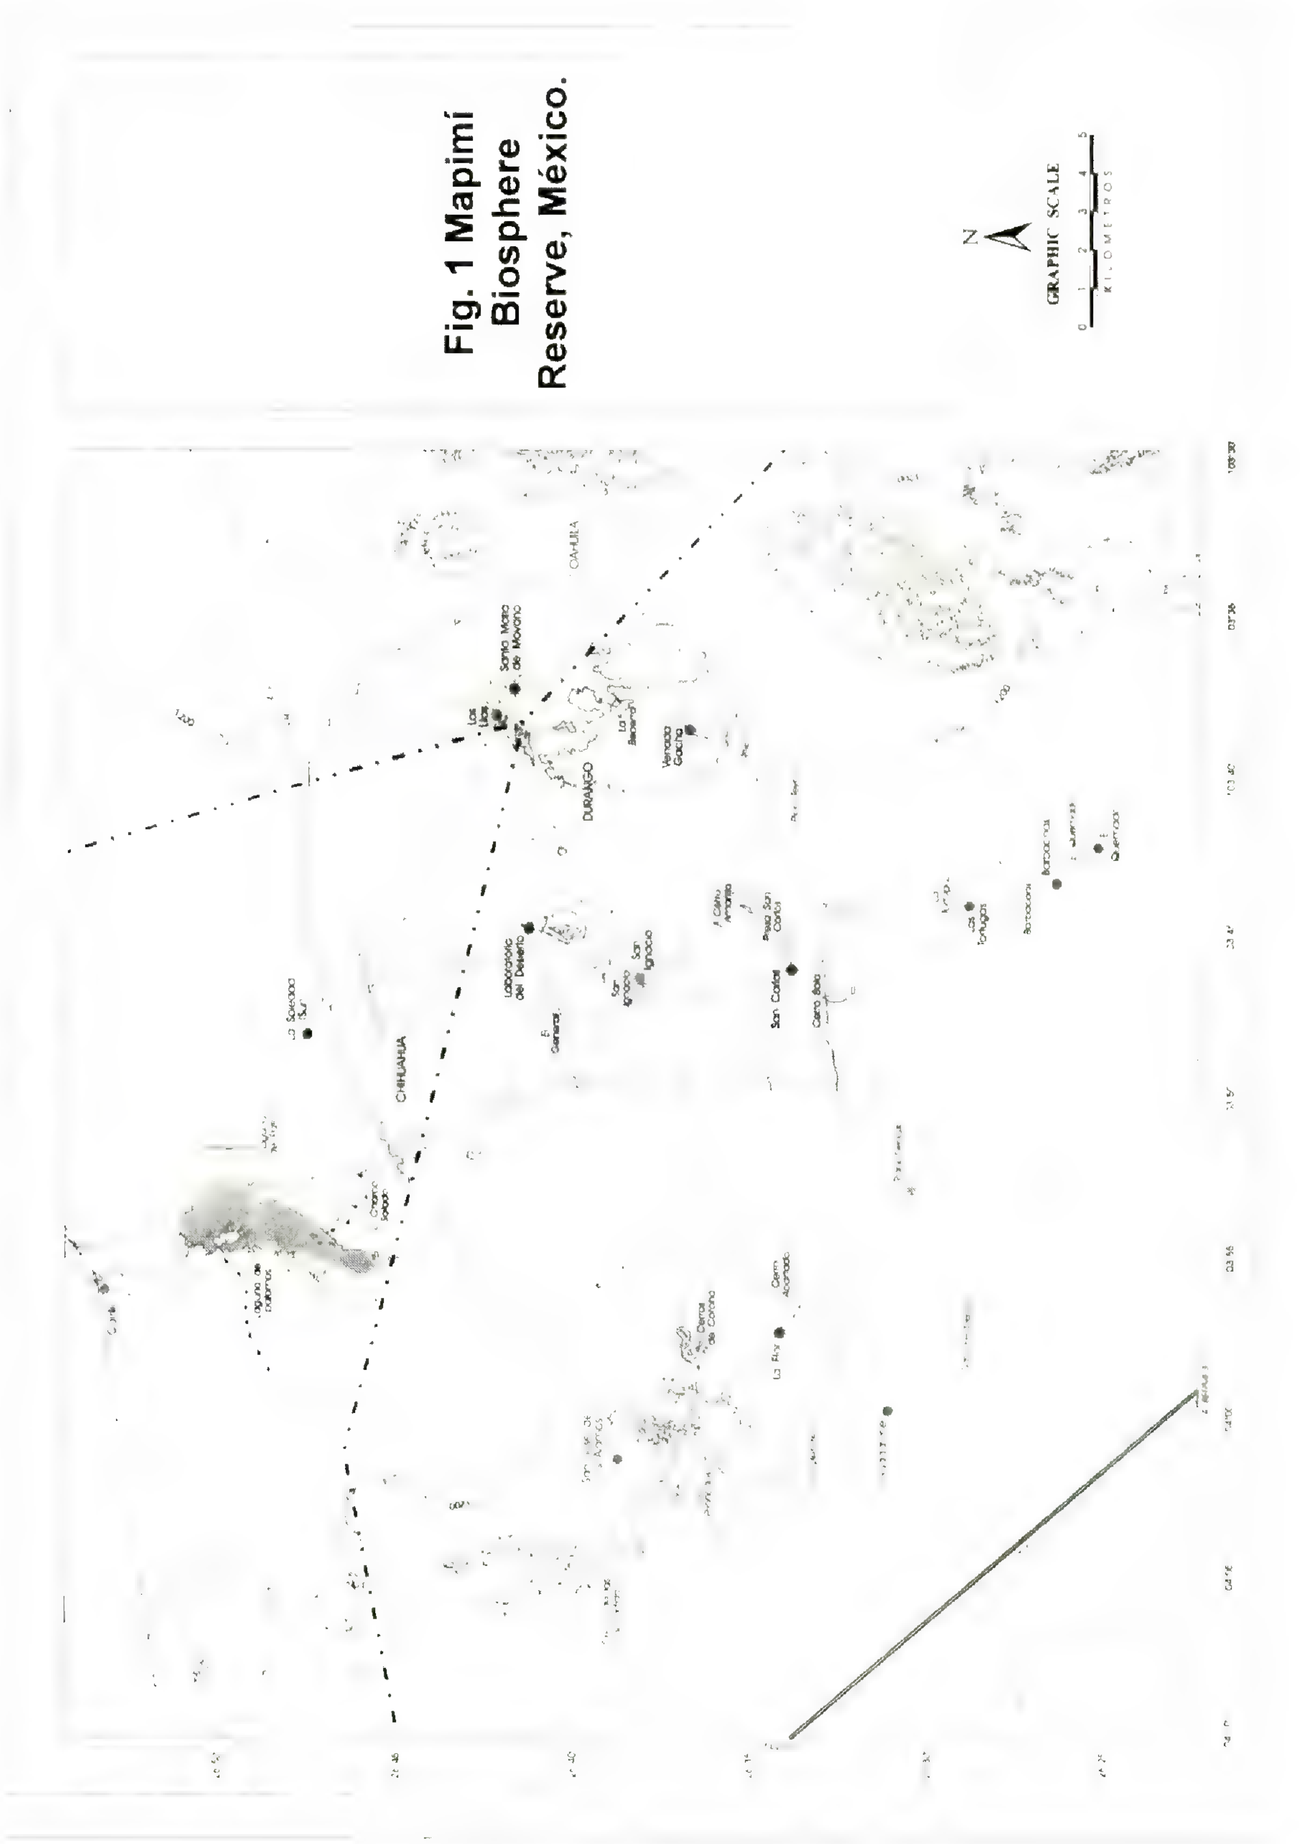

FIG. 1. Map showing location of Mapimí Biosphere Reserve in Mexico.

September. The average annual rainfall is 264 mm. The highest record is 513 mm and lowest is 81 mm, and a mean annual temperature of 20.8º. Elevation is about 1000 m at the lowest zones or "playas" and 1480 m at the summit of the Cerro San Ignacio, the highest point.

VEGETATION

Martínez and Morello (1977) described nine types of physionomic-floristic units for this region of the Mapimí. Later, González (1983) noted, on her description of the vegetation of Durango, desert xerophytic scrub, grasslands and halophytic vegetation as representative types for the region.

On the basis of the biological forms and dominant species, Montaña (1988) grouped vegetation into 76 associations. These associations were grouped into 14 categories of higher rank defined by combinations of dominant life forms. Out of the 35 species, 12 were more widely distributed as dominants: *Prosopis glandulosa* Torr., *Larrea tridentata* (DC.) Cov., *Hilaria mutica* (Buckley) Benth., *Fouqueria splendens* Engelm., *Acacia constricta* Benth., *Flourensia cernua* DC., *Cordia parvifolia* A. DC., *Atriplex acanthocarpa* (Torr.) S. Watson, *Acacia greggii* A. Gray, *Opuntia rastrera* F.A.C. Weber, *Dalea scoparia* A. Gray y *Yucca elata* Engelm.

In general, there are two dominant vegetation types, xerophytic scrub (Chihuahuan desert scrub) and halophytic grasslands, with a great diversity of associations.

Xerophytic scrub (Chihuahuan desert scrub).—This vegetation type is widely distributed in the reserve and is characterized by the dominance of shrubby species with a wide variety of plant associations. Species most commonly represented are: *Larrea tridentata, Prosopis glandulosa, Opuntia rastrera, Acacia constricta* and *Fouqueria splendens*, among others.

Halophytic grasslands.—Grasses are dominant in this vegetation type, and are found, mostly at places with high salt concentrations. Principle dominant species in the associations are *Sporobolus airoides* and *Pleuraphis mutica*.

FLORA

For the vascular flora of the Mapimí Biosphere Reserve 71 families, 242 genera, 403 species and 426 infraspecific taxa are registered. Families and genera with the greatest diversity are shown in Table 1. Endemic species to the Chihuahuan Desert are shown in Table 2. Previously, Ruiz de Esparza (1988) recorded 60 families, 197 genera and 313 species.

There are isolated collections from the Bolsón de Mapimí basin. In the 1980s these collections increased as it was the interest of various studies from Instituto de Ecología A.C. (Carlos Montaña, Antoine Cornet and Rosario Ruiz de Esparza). Recently, from 1994 on, García-Arévalo collected most of the specimens on which this catalogue is based.

Table 1. Most diverse families and genera.

Families	Species	Genera	Species
Asteraceae	68	*Sporobolus*	10
Poaceae	62	*Opuntia*	8
Cactaceae	29	*Aristida*	7
Fabaceae	21	*Acacia*	7

HAROLD KOOPOWITZ. 2002. **Clivias.** (ISBN 0-88192-546-2, hbk.). Timber Press, Inc., 133 S.W. Second Avenue, Suite 450, Portland, OR 97204-3527, U.S.A. (Orders: www.timberpress.com, 800-327-5680, 503-227-2878, 503-227-3070 fax). $34.95, 384 pp, 118 color illustrations, 3 charts, 1 bn/w photo, 2 keys, 1 map, 6" × 9".

Clivia is a small genus (four species) in Amaryllidaceae family from southern Africa. "They are all evergreen herbs with leaves arranged in two rank borne on a thick rhizome." The name honors Lady Charlotte Florentia Clive. "Clivias is the first practical book on this fascinating genus. The result is a comprehensive treatment that covers the history and biology of clivias, and provides profuse information on cultivation, color, and breeding." There are 118 great color photographs. **Contents:** Introduction, What is in a Name?; *Clivia* and *Cryptostephanus*: The Species; The Biology of a Clivia Plant; Cultivating and Growing Clivias; Understanding Clivia Colors; Hybridizing and Growing Clivias from Seed; Clivia Obsession; Standard *Clivia miniata* Hybrids: Orange and Red; Standard *Clivia miniata* Hybrids: Yellow; Standard *Clivia miniata* Hybrids: Pastel Colors; Variegated Clivias; Cyrtanthiflora-type Clivias and Related Hybrids; Novelty Clivias; The Future; Appendix I. Who Was Lady Clive?; Appendix II. Sources of Information; Appendix III. Sources of Plants; Glossary; Map of South Africa; References and Additional Reading; Index of Plant Names.

LEWIS J. MATTHEWS. 2002. **The Protea Book: A Guide to Cultivated Proteaceae.** (ISBN 0-88192-553-5, pbk.). Timber Press, Inc., 133 S.W. Second Avenue, Suite 450, Portland, OR 97204-3527, U.S.A. (Orders: www.timberpress.com, 800-327-5680, 503-227-2878, 503-227-3070 fax). $34.95, 184 pp, 286 color photos, 7 1/4" × 10 1/4".

"Proteaceae is a large and ancient family of incredible diversity in both foliage and flower form. In recognition of this variety, Linnaeus named them after the legendary Greek sea god Proteus, who could change his shape at will." This is a must book for anyone interested in Proteas. Whether you are a grower or the cut-flower industry you will like this book. **Contents:** Introduction; Cultivating proteas; Proteas in the garden; Commercial cultivation; Identification; Glossary; References; Index.

MICHAEL A. DIRR. 2002. **Dirr's Trees and Shrubs for Warm Climates: An Illustrated Encyclopedia.** (ISBN 0-88192-525-X, hbk.). Timber Press, Inc., 133 S.W. Second Avenue, Suite 450, Portland, OR 97204-3527, U.S.A. (Orders: www.timberpress.com, 800-327-5680, 503-227-2878, 503-227-3070 fax). $69.95, 448 pp, 1438 color photos, 1 map, 8 1/2" × 11".

This is a companion volume to *Dirr's Hardy Trees and Shrubs: An Illustrated Encyclopedia* also published by Timber Press. This is truly an encyclopedia of beauty and detail for more than 400 species and nearly 500 additional cultivars and varieties, many of which are illustrated. Even if you are not into woody plants this book will surely please you. The 1438 color photos are worth the price alone.

A SIGNIFICANT NEW POPULATION OF THE RARE SEMAPHORE PRICKLYPEAR CACTUS, *OPUNTIA CORALLICOLA* (CACTACEAE)

Keith A. Bradley and Steven W. Woodmansee

The Institute for Regional Conservation
22601 S.W. 152 Ave.
Miami, FL 33170, U.S.A.
bradley@regionalconservation.org

ABSTRACT

A newly discovered population of *Opuntia corallicola* is reported. This new population is in Miami-Dade County, Florida, 145 km north of what was believed to be the last remaining population in the wild.

RESUMEN

Se informa de una población recientemente descubierta de Opuntia corallicola. Esta nueva población está en el Condado Miami-Dade, Florida, 145 km al norte de lo que se pensaba que era la última población que crecía silvestre en la naturaleza.

The semaphore pricklypear cactus, *Opuntia corallicola* (Small) Werderm. (Cactaceae) is considered one of the most threatened plants in the United States (Stiling et al. 2000). It is endemic to the Florida Keys, first discovered by John Kunkel Small in 1919 (Small 1930). Previously, Florida plants were thought to be conspecific with *O. spinosissima* P. Miller of Jamaica, but research has shown Florida plants to be distinct (Austin et al. 1998; Gordon & Kubisiak 1998). The Florida Keys are a chain of islands at the southern tip of Florida, extending in an arc approximately 320 km from the Dry Tortugas in Monroe County north to Soldier Key in Miami-Dade County.

Small's discovery of *O. corallicola* was made on Big Pine Key, an island in the lower Florida Keys. Plants were known from this island until the 1960s when the last plants were eliminated by poaching and road construction. Sometime during the 1960s a new population was discovered on Little Torch Key, an island immediately west of Big Pine Key. Subsequently, the station was acquired by The Nature Conservancy. Small (1930) also reported the species from Key Largo, an island in the upper Florida Keys just over 80 km north of Big Pine Key, although we have been unable to locate specimens or other reports from this island.

The population on Little Torch Key presently has only nine adult plants (C. Bergh, pers. comm.). Plants at this site are threatened, originally by poaching, and subsequently by both an exotic moth and its inability to sexually reproduce. The exotic moth, *Cactoblastis cactorum* Berg (Lepidoptera: Pyralidae),

was discovered in the Florida Keys in 1989 (Habeck & Bennett 1990). This pest infested two of the remaining wild plants, killing one of them (Stiling & Moon 2001). While vegetative reproduction results in numerous recruits (C. Bergh, pers. comm.), Negrón-Ortiz (1998) found that fruit set in the species is rare. Less than half of the seeds set were viable in laboratory culture, but no seedling recruitment was found under natural conditions. The few seeds produced are believed to result from agamospermy, asexual seed formation common in Cactaceae (Negrón-Ortiz 1998). Negrón-Ortiz (1998) proposed that the species is unable to reproduce sexually either because of meiotic problems resulting from polyploidy, or because the existing plants are self-incompatible.

The authors and George D. Gann have been conducting extensive field work in Biscayne National Park (BNP) in part to update the floristic inventory published by Stalter et al. (1999). The park is comprised of 42 islands of the upper Florida Keys in Miami-Dade County. On November 20, 2001, the authors discovered *O. corallicola* on Swan Key. This island is within the southern boundary of BNP and is approximately 140 km from Big Pine Key, the closest historically documented occurrence, and 145 km from Little Torch Key, the site of the other known population. On January 31, 2002 a subsequent survey was conducted and 570 plants with trunks were found. The population consisted of plants of diverse sizes and ages, including flowering individuals.

The new Swan Key population occupied approximately 0.5 km by 10 m along the edge of a rockland hammock. Plants were in partial sun to shade growing on Key Largo Limestone, sometimes in light leaf litter and duff. While plants were found primarily along the edges of the hammock, some small plants were found inside the shady interior of the hammock up to 50 m from the edge. Associated plant species include *Acanthocereus tetragonus, Agave decipiens, Borrichia arborescens, Bursera simaruba, Canella winterana, Capparis flexuosa, Coccoloba diversifolia, Conocarpus erectus, Eugenia foetida, Guapira discolor, Metopium toxiferum, Pithecellobium keyense,* and *Sideroxylon celastrinum.*

We believe that *O. corallicola* merits Federal Endangered Species status. Even with the discovery of this new population, only two populations of this species are known. Both populations are threatened by *Cactoblastis cactorum. Opuntia corallicola* is being considered by the U.S. Fish and Wildlife Service as a candidate for listing (Federal Register 1999; Bradley & Gann 1999). Endangered Species status would enable the National Park Service to focus on the management and protection of the species. We encourage the U.S. Fish and Wildlife Service to continue with the listing process and we support the establishment of an agreement with the National Park Service to focus on the management and protection of the species.

Voucher specimen: **FLORIDA. Miami-Dade Co.:** Biscayne National Park; Swan Key, between Old Rhodes Channel and Broad Creek, S of Old Rhodes Key, just N of the Monroe Co. line, common along the edge of rockland hammock, 31 Jan 2002, *Bradley* 2152 (FTG).

ACKNOWLEDGMENTS

The BNP inventory was funded through the National Park Service (NPS) Inventory and Monitoring Program, as part of the South Florida / Caribbean Network of Parks Inventory of Vertebrates and Vascular Plants. We would like to thank NPS ecologist Matt Patterson and NPS biologist Toby Obenauer. Fairchild Tropical Garden (FTG) provided funding for the follow up survey which was conducted with FTG biologists Meghan Fellows and Jennifer Possley. Robert Pemberton, entomologist for U.S. Department of Agriculture–Agricultural Research Service, also assisted with the follow-up survey. George Gann, Doria Gordon, Dawn Jennings, Colette Jacono, and an anonymous reviewer provided helpful comments on the manuscript.

FRANCIS HALLÉ. Translated and with foreword by DAVID LEE. 2002. **In Praise of Plants.** (ISBN 0-88192-550-0, hbk.). Timber Press, 133 SW Second Ave., Suite 450, Portland, OR 97204-3527, U.S.A. (Orders: www.timberpress.com, 800-327-5680, 503-227-2878, 503-227-3070 fax). $24.95, hbk., 334 pp., 99 line drawings, 6" × 9".

Contents.—**Chapter 1.** Plants, Animals, and Humans. **Chapter 2.** A Visit to the Landscape of Form. **Chapter 3.** The Cell. **Chapter 4.** Plant Biochemistry in a Nutshell. **Chapter 5.** Evolution. **Chapter 6**. Of Other Living Beings. **Chapter 7.** Ecology. The book concludes with an Epilogue, References, and Index. This is a book that invites you to look closer at the world of plants and animals around us. The first chapter contains a section on "*Comparing Plants and Animals*" and the closing paragraph will give you a taste of what is to come. "What are plants? Despite the important place they occupy in our landscapes, they are often ignored or scorned by modern biologists, by loggers, and the old foresters, by people in general. Does that place us on a contrasting quest to understand plants? Plants please most women, they pleased Christ and the Buddha, the last emperor of China, the scholars of earlier centuries, and they have pleased innumerable artists and philosophers, including Goethe, Cioran, Colette, Valéry, Mandela, Dürer, Giono, Hugo, and Rilke. First what do plants resemble and how can we comprehend the forms they have adopted."

ABSTRACT

Eight taxa are reported as new to continental United States and the state of Florida: *Alstonia scholaris*, *Bromelia pinguin*, *Costus pulverulentus*, *Enydra fluctuans*, *Eucalyptus torelliana*, *Hygrophila difformis*, *Khaya senegalensis*, and *Oxalis triangularis* var. *papilionacea*. The reports for the non-native *Berberis bealei* and *Canna glauca* and the native *Rudbeckia auriculata* are the first for Florida. The occurrence of *Didiplis diandra* in Florida is verified.

RESUMEN

Se citan ocho taxa como nuevos para los Estados Unidos continentales y el estado de Florida: *Alstonia scholaris*, *Bromelia pinguin*, *Costus pulverulentus*, *Enydra fluctuans*, Eucalyptus torelliana, Hygrophila difformis, Khaya senegalensis, y Oxalis triangularis var. papilionacea. Las citas de las no nativas *Berberis bealei* y *Canna glauca* junto con la autóctona *Rudbeckia auriculata* son las primeras para Florida. Se verifica la existencia de *Didiplis diandra* en Florida.

Continuing study on the flora of Florida and for the *Guide to the Vascular Plants of Florida, Second Edition* (Wunderlin & Hansen, in press) has resulted in 12 taxa new to the state. Eight of these, all introduced, also likely represent new records for the continental United States. Three additional species, two introduced and one native, are new records for Florida, and the occurrence of *Didiplis diandra* is verified for the state. This paper emphasizes the potential for more natives to be discovered in Florida, as well as the high probability for invasion by exotics. Of the over 4,119 taxa of plants in Florida, 1,305 (32%) are non-native (Wunderlin & Hansen 2002). The criteria for including plants in the flora follow that of Wunderlin and Hansen (2000, p. 4).

SPECIES NEW TO CONTINENTAL UNITED STATES AND FLORIDA

Alstonia scholaris (L.) R.Br.—Palm Beach Co.: Village of Wellington, wetland preserve at Wellington Mall, T44S, R11E, Sec. 13, 22 Feb 2002, *Miller s.n.* (USF). Native to the Indo-Pacific area and occasionally cultivated in Florida, "dita" (or "white cheesewood") can be expected as an escape. The seeds are wind dispersed,

and the plant at Wellington Mall apparently became established from nearby plantings. It now has been eradicated from the site.

Bromelia pinguin L.—Hillsborough Co.: Riverside Park, Temple Terrace, 6 Dec 2001, *Dickman s.n.* (USF). Native to tropical America, "pinguin" is an escape from cultivation in central Florida.

Costus pulverulentus C. Presl—Orange Co.: Valencia Community College, East Campus, 700 block of North Econlockhatchee Trail, ca. 10 mi E of Orlando, T22S, R31E, Sec. 19, edge of riverine hammock, 1 Nov 2000, *Myers* 2 (USF). Seminole Co.: Sweetwater Park, 100 block of Magnolia Street, Oviedo, 28°40.668'N, 81°12.352'W, oak hammock, 2 Sep 2001, *Myers 290* (USF). Native to tropical America and escaped from cultivation in Orange and Seminole Counties.

Enydra fluctuans Lour.—Hillsborough Co.: Tampa, ditch along the E side of Manhattan Avenue just S of the intersection of Manhattan Avenue and Rembrandt Drive on the Interbay Peninsula, T30S, R18E, Sec. 16, 7 Apr 2000, *Shuey & Poyner s.n.* (USF). "Buffalo Spinach" is a pantropical aquatic plant, sometimes cultivated for use in Asiatic foods. It is potentially highly invasive, readily rooting from stem fragments.

Eucalyptus torelliana F. Muell.—Palm Beach Co: E of the intersection of Alternate A1A and Hood Road, Palm Beach Gardens, 14 Jun 2001, *Miller s.n.* (USF). "Torell's eucalyptus" or "cadaga" is native to Australia and escaped from cultivation in southern Florida. Trees and seedlings occur in a designated preserve, these apparently coming from a development north of the site (Frenchman's Creek) where this species is used in landscaping.

Hygrophila difformis (L.) Blume—Hillsborough Co.: spreading on clayey shelf of man-made pond on N side of Cherry Street, 0.7 mi W of park Road, Plant City, T28S, R22E, Sec. 21, SE $^1/_4$ of SW $^1/_4$, 5 May 1999, *Hansen & Wunderlin 12893* (USF). "Water wisteria," native to southeastern Asia, is often grown as an aquarium plant. The Hillsborough County plants probably originated as a discard from an aquarium and have now formed a sizable population in the pond. It easily propagates from stem fragments and has high invasive potential in lakes, ponds, and rivers. When growing out of the water, it is erect and flowers profusely. However, mature seeds were not observed by Hansen and Wunderlin.

Khaya senegalensis (Desr.) A. Juss.—Collier Co.: Collier Seminole State Park, Campsite #7 of 1–19, T51S, R27E, Sec 27, SE $^1/_4$, SW $^1/_4$, SE $^1/_4$, rockland hammock, 17 Apr 1998, *Hattaway CS0319* (USF). "African mahogany" is native to Africa and widely grown as a street and timber tree in the tropics (Irvine 1961). It has the potential to invade disturbed tropical forests. It is naturalized in Western Australia (Csurhes & Edwards 1998). The population in Collier-Seminole State Park consisted of several trees (one very large), but these have now been eradicated.

Oxalis triangularis A. St.-Hil. subsp. **papilionacea** (Hoffmanns. ex Zucc.)

Lourteig—Leon Co.: several plants naturalized in deeply shaded loam along roadside of Duparc Circle near its W junction with Lakeshore Drive, Tallahassee, 23 Feb 2001, *Anderson 19691* (FSU). "Purpleleaf false shamrock," native to South America, is occasionally cultivated in North America for its purple leaves. The Leon County site is the only location known where it is naturalized in North America.

SPECIES NEW TO FLORIDA

Berberis bealei Fortune—Leon Co.: naturalized single shrub (vegetative) in moist loam of deeply shaded creek swamp NNE of marker 20 in Elinor Klapp-Phipps Park, W of Meridian Rd, N of Tallahassee, T2N, R1W, Sec. 36, NW 1/4 of NW 1/4, 30 May 1996, *Anderson 16530* (FSU); flowering shrub in pine-oak woodland remnant on S side of Duparc Circle just N of Lakeshore Drive, Tallahassee, 23 Feb 2001, *Anderson 19688* (FSU). These two sites are about 1.6 miles apart. Naturalized in Delaware, Virginia, North Carolina, South Carolina, Georgia, and Alabama (USDA, NRCS 2002), "Beale's barberry" or "leatherleaf mahonia" is now reported from Florida. It is an evergreen shrub native to China and frequently cultivated outside its native range.

Canna glauca L.—Madison Co.: along US 90, Greenville, 29 July 1967, *Beckner 1885* (FLAS). The species is native to tropical America and previously known in the United States only from Louisiana and Texas where it is considered to be native (Kress & Prince 2000). It is escaped from cultivation at one site in Madison Co., Florida, where it occurs as frequent clumps around several burned-out houses near a lake where it is spreading vegetatively and by seed.

Didiplis diandra (Nutt. ex DC.) A.W. Wood—Sarasota Co.: Pinelands Reserve, ca. 1 mi SW of Lower Myakka Lake, T38S, R19E, Sec. 1, freshwater marsh, 6 Apr 1998, *Morrison 98064-1* (USF). "Waterpurslane," a submergent or emergent aquatic is apparently native from Minnesota and Wisconsin south to Georgia, Alabama, Mississippi, Louisiana, and Texas (USDA, NRCS 2002), and now documented in Florida. This species has been reported (sometimes as *Peplis diandra* Nutt. ex DC.) for Florida in many floras, (e.g., Chapman 1860; Correll & Johnston 1970; Crow & Hellquist 2000; Fassett 1957; Fernald 1950; Gleason & Cronquist 1963, 1991; Radford et al. 1968; Small 1933). The basis for these reports is not known. No Florida material was found at NY, the principal repository for A. W. Chapman and J. K. Small collections (Stafleu 1967). A search of the herbaria at FLAS and FSU also yielded no Florida material. It is not reported by Godfrey and Wooten (1981), Clewell (1985), or Wunderlin (1982, 1998). The species is apparently rare in much of its natural range, but is rather inconspicuous and perhaps has been overlooked. It is sometimes grown as an aquarium plant, but it is not believed that the Sarasota plants represent an introduction.

Rudbeckia auriculata (Perdue) Kral—Walton Co.: along US 331, 0.5 mi N of

FL 2 at Gordon, ca. 6.5 mi S of Paxton, roadside bog, 17 Aug 2000, *Searcy s.n.* (USF). A rare species, "eared coneflower" is known only from Georgia, Alabama (USDA, NRCS 2002), and now Florida. A second attempt to locate the plants was unsuccessful.

ACKNOWLEDGMENTS

We thank Steve Dickman, Bobby Hattaway, Ray Miller, Melissa Morrison, Steven Myers, Darryl Searcy, and Allen Shuey for bringing various of these species to our attention and providing collections.

CRYPTOCORYNE BECKETTII COMPLEX (ARACEAE) INTRODUCED AT A FLORIDA SPRING

Colette C. Jacono

United States Geological Survey
Florida Caribbean Science Center
7920 NW 71ST St.
Gainesville, Florida, 32653, U.S.A.

ABSTRACT

A vegetative population of *Cryptocoryne* (Araceae), introduced at a Florida spring, appeared to represent three closely related species in the *C. beckettii* complex: *C. beckettii Thw.* ex Trimen, *C. wendtii* de Wit and *C. undulata* Wendt. Individuals of *C. undulata* were true to type and could be delineated at the site. Intergradation of diagnostic features was common in others, upon transplanting and flowering. While some transplants produced spathes characteristic of either *C. wendtii* or *C. beckettii*, intermediates between the two species were common. Neither *C. beckettii* nor *C. wendtii* could be delineated at the site. The seclusion of the stream and the integrity of native plant communities have likely prevented dispersal downstream.

RESUMEN

Una población vegetativa de *Cryptocoryne* (Araceae), introducida en un manantial de Florida, al parecer representa tres especies estrechamente relacionadas del complejo *C. beckettii*: *C. beckettii* Thw. *ex* Trimen, *C. wendtii* de Wit y *C. undulata* Wendt. En el lugar de estudio, fueron clasificados como verdaderos tipos ejemplares de *C. undulata*. En otros ejemplares, después del transplante y floración, fue común observar intergradación de caracteres diagnósticos. Aún cuando algunos transplantes produjeron espatas, características de *C. wendtii* o de *C. beckettii*, fue común observar ejemplares con características intermedias de ambas especies. Las especies *C. beckettii* y *C. wendtii* no fueron delineadas en el sitio de estudio. La condición de aislamiento del manantial y la condición íntegra de las comunidades de plantas nativas han impedido probablemente la dispersión corriente abajo.

INTRODUCTION

Cryptocoryne Fisher ex Wydler are highly sought-after and commercially marketed as decorative plants for tropical aquariums. The most commonly cultivated species belong to the *C. beckettii* complex, a uniform and specialized group endemic to Sri Lanka (Jacobsen 1977; Jacobsen 1987; de Graaf & Arends 1986).

In their native range, members of the *Cryptocoryne beckettii* complex inhabit pristine rivers and springs. In some areas, they form large submersed or emergent stands (Jacobsen 1987), although some populations have declined from commercial collecting and habitat destruction (de Graaf & Arends 1986). Species in this group commonly root in the sand and silt that overlay rocky, shallow streambeds (de Graaf & Arends 1986; Rataj & Horeman 1977) and occupy

shady, sheltered niches rarely inhabited by other plants (Jacobsen 1977; Doyle 2001). They adapt readily to terrestrial conditions and flower with water draw down, when leaves become emersed and the roots well aerated (Jacobsen 1977; Clark 1991). Vegetative reproduction is important in population establishment and expansion (Jacobsen 1977). In cultivation, *C. beckettii* members are hardy and vigorous, propagating abundantly by rhizomes and stolons, and enduring hard, calcium rich water (Miller 1998; Rataj & Horeman 1977).

In treating *Cryptocoryne* for the Flora of Ceylon, Jacobsen (1987) portrayed four species as closely related within the *Cryptocoryne beckettii* complex: *Cryptocoryne walkeri* Schott, *C. beckettii* Thw. ex Trimen, *C. wendtii* de Wit, and *C. undulata* Wendt. Although mainly diploids, all four have been found as triploid species and several combinations within the complex have resulted in the formation of hybrids (Jacobsen 1977; Arends et al. 1982; Jacobsen 1987). Because *Cryptocoryne* share many similarities in their vegetative features, an inflorescence is requisite for species identification. Determination of the species in the *C. beckettii* group rests on subtle differences in the morphology of the spathe, which is a fleshy, ornate bract enclosing the inflorescence. Key features of the spathe include the size and color of the collar and the shape and degree of twist of the terminal limb. Since differences in these characters are essentially quantitative, it has been recognized that the four taxa could prove to constitute a single species (Jacobsen 1987).

Wunderlin's (1998) inclusion of *Cryptocoryne wendtii* de Wit as an introduced component of the Florida flora was the first recording of this Southeast Asian genus for North America. Soon after, Rosen (2000) reported *C. beckettii* Thw. ex Trimen as introduced to Texas, followed by Doyle (2001) who detailed its expansion and spread in the upper spring-fed regions of the San Marcos River.

Rosen's description of *C. beckettii* from the San Marcos River, Texas, was based on vegetative material (Rosen 2000). Doyle (2001) reported that *C. beckettii* had been adequately confirmed in Texas after K. Sanders and D. Lemke identified flowering transplants. Wunderlin's report of *C. wendtii* in Florida was similarly based on a sterile specimen collected at Rainbow Springs Aquatic Preserve, Florida, in 1989. The objective of this inquiry was to confirm the persistence of *Cryptocoryne* at Rainbow Springs Aquatic Preserve and to collect material for cultivation and subsequent species determination from flowering plants.

The Rainbow River is a karstic, spring-fed stream receiving artesian groundwater that is high in clarity, rich in soluble carbonates and moderate in temperature (USGS 1999). The run traverses 8 km before joining the Withlacoochee River near the town of Dunnellon. A site of exceptional scenic beauty and a popular destination for recreation, it was designated the Rainbow Springs Aquatic Preserve in 1986 (Florida Statute 258.39 [32]).

METHODS

In May 2000 and in June 2001, approximately 50 individuals were uprooted from the *Cryptocoryne* colony found at Rainbow Springs Aquatic Preserve. Four sided, open-ended aluminum units (0.25 m^2) enclosed in double netting were placed over each area during sampling to delineate the sampling area and to trap stray plant fragments. Sampling attempted to localize variation observed in leaf color and in total represented seven areas within the colony. Samples were transplanted to 10 cm pots in a bark and peat-based potting medium and cultivated out of water, outdoors, with shade and screening, during the warmer months. Transplants established readily, losing submersed leaves and producing new terrestrial foliage. Pots were moved to a heated greenhouse when nighttime temperatures dropped below 10°C. Flowering began in December and continued through July. The inflorescences survived for several days and were documented with photographs and voucher specimens before decline. On pressing and drying, the inflorescences lost color and the angle of terminal limbs appeared more upright. Photography provided for better study than did prepared specimens. Species identification was based on Jacobsen (1987).

To assess plant density, the extent of subsurface rhizomes, and the potential of hand removal as a control method, total vegetation was harvested from two 0.25 m^2 areas within the colony. Limestone gravel was removed with fingers as necessary to extract plants in whole (i.e. with basal parts and some extent of rhizomes intact). Roots were harvested to approximately 10 cm deep. Top portions of plants were separated from subsurface material (roots). Weight was taken before and after material was oven dried at 60°C.

Adjacent, sterile colonies of *Myriophyllum* and Cyperaceae were sampled for subsequent transplanting, flowering and identification. *Myriophyllum* was tank cultivated in 50 cm of water, the sedge was grown under terrestrial conditions.

RESULTS AND DISCUSSION

Cryptocoryne was found persisting and well established at Rainbow Springs Aquatic Preserve, in a shaded cove of a spring fed stream. The plants grew submersed in an area of approximately 130 m^2. Water depth ranged from 28 to 75 cm, although outlying runners extended to crevices as deep as 150 cm. The low growing plants reached an average height of 7 cm. The vegetation consisted of dense mats that grew to the exclusion of other macrophytes.

Transplants from the *Cryptocoryne* colony produced approximately 100 inflorescences. Voucher specimens and photographs documented 49 representative inflorescences. Twenty-five appeared characteristic of three species in the *C. beckettii* complex: *C. undulata*, *C. beckettii*, and *C. wendtii* (Fig. 1–3). However, 20 were intermediate between *C. beckettii* and *C. wendtii*. *Cryptocoryne*

FIG. 1. *Cryptocoryne undulata* Wendt.

undulata was the only species that could be delineated at the Preserve. The remaining, and predominant, vegetation at the site could not be delineated as either *C. beckettii* or *C. wendtii*.

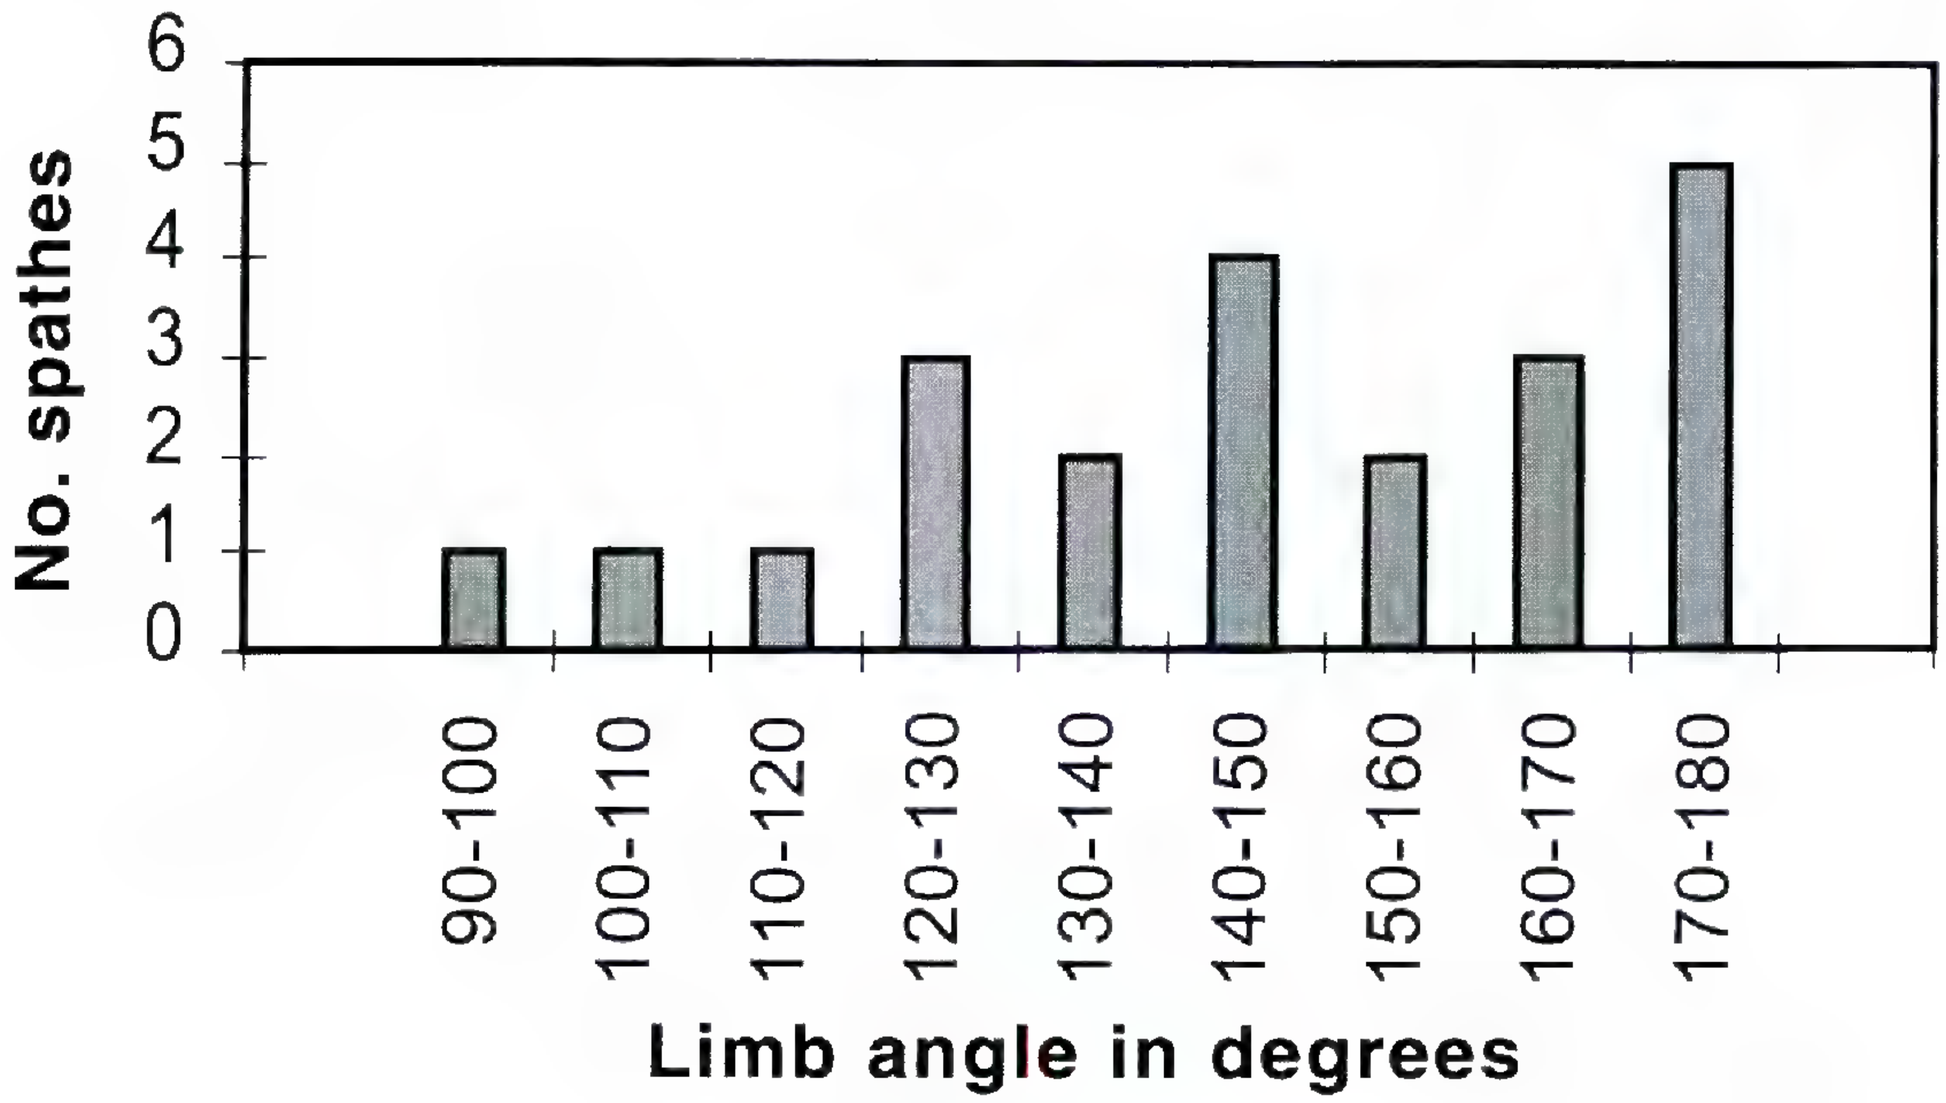
FIG. 2. *Cryptocoryne wendtii* de Wit.

Spathes of *C. undulata* were uniform in color and morphology. The collar zone graded from yellow to cream and the terminal limb darkened from yellow to golden brown upon maturing. The terminal limb was always nearly doubly twisted and positioned diagonally to the axis of the spathe tube. *Cryptocoryne undulata* was delineated within a small (approx. $4m^2$), distinct region of the colony. Submersed, unopened inflorescences found within this region were similarly yellow at the collar zone and on the inside of the unfurled limb.

Submersed leaf blades of *C. undulata* were narrowly lanceolate. They ranged in length from 4.0 to 9.0 cm (mean 6.1, SD 1.5) and in width from 0.7 to 1.8 cm (mean 1.3, SD 0.4). Bases were cordate to cuneate and the entire leaf margin was crisped. Submersed leaf color was dark brownish green on the adaxial surface; abaxial sides and petioles were maroon. Terrestrial plants of *C. undulata* produced smaller lanceolate leaves with acuminate bases and margins that were crisped only along the leaf base. Terrestrial leaf color was deep green with veins and petioles red.

While four transplants produced spathes characteristic of *C. wendtii*, and 17 characteristic of *C. beckettii*, more than 20 individuals appeared intermedi-

ate and could not be determined to the species level. Jacobsen (1987) separated *C. beckettii* from *C. wendtii* by the angle on the terminal limb of the spathe. The limb of *C. beckettii* is more upright or sub-erect, and twisted to recurved while that of *C. wendtii* is obliquely twisted, often extending into a tail (Jacobsen 1987). Jacobsen (1976) noted these characters as difficult to describe and variable, partly in response to environmental conditions. In the present study, the key characters were found to intergrade across a population grown under greenhouse conditions. The angle of the terminal limb (as measured from the spathe tube) ranged widely from 93°to 175°(Table 1). Limbs assumed different shapes, as well as angles, and spathes frequently shared diagnostic features. For example, spathes with sub-erect limbs (limbs not obliquely twisted) were found extending into well-defined tails (Fig. 4b).



Jacobson (1976; 1987) further depicted the terminal limbs of *C. beckettii* as yellowish to brownish and those of *C. wendtii* as yellowish to purplish brown. In this study limbs varied in color from golden to green to greenish or purplish brown. On occasion they darkened with maturity. Limb color did not always correlate with limb position, for example, greenish brown limbs ranged from more erect to nearly perpendicular (Fig. 4d) and true green limbs were found twisted at an angle (Fig. 4a). Thus, in form and color many individuals in this study appeared intermediate between *C. beckettii* and *C. wendtii*.

The identity of those individuals that could be determined according to floral characteristics was often in question when apparently distinct individuals (*C. beckettii* and *C. wendtii*) were traced back to the same sampling block at the Preserve (Fig. 5 and representative specimens *Jacono 373* vs. *Jacono 368*). As a result, clear clonal populations, although expected for long established, vegetatively reproducing plants, could not be delineated for either *C. beckettii* or *C. wendtii*.

Submersed inflorescences found in sunny shallow areas had purple collar zones and green inner limbs. However, with spathes tightly furled, they contributed little in separating *C. beckettii* from *C. wendtii*, and merely confirmed the ability of this type to flower *in situ*.

Plants of this type (*C. beckettii*, *C. wendtii*, and the intermediates) demonstrated differences in leaf color while growing at the Preserve. Submersed leaf color of the adaxial surfaces varied from green marbled with brown to pink infused with green venation. Abaxial sides were violet to pink. This color variation was apparent in zones and may be attributed to factors of substrate and sunlight at the site. Green-brown plants grew in organic sediment under continuous shade of the tree canopy; pink plants grew on limestone substrate in zones of higher sunlight. After transplanting, the terrestrial leaves that replaced the submersed vegetation were without variation and uniform in color. The submersed leaves were lanceolate to ovate with cordate bases and sinuous margins. The length of their leaf blades ranged from 3.8 to 9.6 cm (mean 6.2, SD 1.5)

Table 1. Distribution of limb angles (measured from the spathe tube) of 22 inflorescences photographed.

and their width measured 1.1 to 3.3 cm (mean 2.2, SD 0.6). Terrestrial leaves were smaller and narrowly ovate with cordate bases, olive-green adaxial surfaces and violet on the abaxial side.

Variability and intergradation of the features upon which these species are based prevented delineation of *C. beckettii* from *C. wendtii*. While certain individuals seemed easy to place to the species level, they could not be traced back to distinct areas at the site. Other individuals were intermediate and could not be determined to species. Regardless of spathe morphology, terrestrially grown transplants within this type were consistently uniform in vegetative features. The predominating *Cryptocoryne* material at the Preserve can only be described as *C. beckettii* sensu lato.

The *Cryptocoryne* subsurface biomass consisted of large amounts of roots, rhizomes and stolons that were difficult to uproot by hand. Roots were well entrenched in contrasting substrates: silty, organic sediment near the shoreline and pebbled to rocky limestone extending into the stream.

Plant density values were 1480 plants / m^2 for *Cryptocoryne beckettii* s.l. and 1880 plants / m^2 for *C. undulata*. Dry roots of *C. beckettii* s.l. weighed nearly four times more than dry top growth: dry roots of *C. undulata* weighed eight times that of corresponding top growth (Table 2).

Like many aroids, *Cryptocoryne* employ contractile roots to adjust plant level after heaving or flooding (Bown 1988). Tiny rootlets sent deep into the rock use root pressure to contract in length and pull the roots farther into the

FIG. 3. *Cryptocoryne beckettii* Thw. ex Trimen.

Cryptocoryne beckettii s.l.	1480	251g	20 g	426g	74g	3.7

substrate. This adaptation firmly anchors plants in swift currents and likely accounts for the deep rooting in limestone substrate at the Preserve, complicating mechanical removal without destructive draglines or dredging.

Shortened runners, basal shoots, were formed at the base of both submersed and transplanted material of all three species. Jacobsen (1987) described these "bulbil-like runners" on forms of *C. wendtii* and *C. undulata*, but did not report them for *C. beckettii*. Small (< 5mm), abundant (up to 8–20 per individual), and fragile, the shoots are loosely associated with the mother plant and readily break off. They quickly develop an initial root and primary leaf to establish as new plants. Kane et al. (1999) successfully employed basal shoots for the *in vitro* propagation of *C. wendtii*. At the Preserve, basal shoots were abundant in springtime. In transplants, they provided the flush of new season growth after spring flowering. Walking on submersed plants can dislodge basal shoots, which immediately sink to the bottom. Conversely, dislodged rhizomes float on the water surface. Because of their abundance and small size, the shoots are difficult to contain and may be carried downstream with bottom currents; they may be more effective than rhizome fragments as propagules for downstream spread.

Reproduction in *Cryptocoryne*, like other submersed macrophytes, is primarily accomplished through vegetative structures. Rhizomes, runners (stolons) and basal shoots provide multiple means for expansion of an apparently well-suited population at Rainbow Springs Aquatic Preserve.

Submersed inflorescences were observed in April and June on both types of *Cryptocoryne* at the Preserve. In their native range, *Cryptocoryne* commonly grow submersed during rainy periods and emerge to flower when seasonal water levels drop (Jacobsen 1977). Submersed inflorescences, while not uncommon in nature, must emerge to be insect pollinated before forming seeds. Typically short-lived, the seeds may be dispersed in water but are not vectored long distances over land (Bown 1988; Jacobsen 1976; Bogner 1987). Constant water level ensured by the spring flow should keep the inflorescences of submersed plants underwater. However, species in the *C. beckettii* complex are well adapted to terrestrial life (Jacobsen 1977) and runners could establish amphibious plants that might flower along the damp, shady shoreline at the Preserve.

Cryptocoryne was found encroaching on adjacent *Sagittaria kurziana* Glück, *Myriophyllum heterophyllum* Michx. and a continually inundated popu-

lation of *Rhynchospora colorata* (L.) H. Pfeiff. Several meters downstream, *Zizania aquatica* L., *Rorippa floridana* Al-Shehbaz & Rollins, *Ludwigia repens* J.R. Forst., *Sagittaria lancifolia* L., *Hydrocotyle umbellata* L., *Chara, Fontinalis, Utricularia, and Leersia* spp. contributed to one of the few intact aquatic communities remaining at the Preserve. The natural vegetation may curtail the downstream spread of *Cryptocoryne* by trapping dislodged rhizomes and shoots. Extensive underwater monitoring conducted in 1996 and 2000 detected no additional sites with *Cryptocoryne* at Rainbow Springs Aquatic Preserve (P. Sleszynski, pers. comm.).

Assessing Risks

In North America, weedy infestations of *Cryptocoryne beckettii* sensu lato may be limited to karstic spring environments of the southern states. Laboratory experiments demonstrated that four *Cryptocoryne* species, *C. affinis* Hook.f., *C. cordata* Griffith, *C. elliptica* Hook.f. and *C. minima* Ridley, effectively used bicarbonate as the main carbon source when pH ranged between 7.5 and 9.1 (Cheng and Mansor 2000). In high pH (>7.0), hard water systems, relatively large amounts of dissolved inorganic carbon exist as bicarbonate (Spencer and Bowes 1990). At Rainbow Springs Aquatic Preserve the spring water is consistently alkaline and carbonate-rich. Within the last decade pH ranged from 7.87 to 8.27 (USGS 1999). Total hardness value, last determined in 1980, was 58 mg/L, measured as calcium carbonate, and noncarbonate hardness was 3 mg/L, expressed as equivalents of calcium carbonate, indicating a high level of carbonate in the water (USGS 1999). Similar pH values (7.6 to 8.0) were recorded near the headspring of the San Marcos River, although hardness values were not determined (USGS 2000). The ability of *Cryptocoryne* to selectively use bicarbonate under alkaline conditions may contribute to its successful colonization at karstic spring-fed streams in Florida and Texas.

The original *Cryptocoryne* "mother plants" were probably planted at Rainbow Springs Aquatic Preserve before 1986 when the system came under state ownership. Now well established, its potential for dispersal there is considerable. In the San Marcos River, disturbance caused by wading and sporting activities are suspected to contribute to the proliferation of *Cryptocoryne beckettii* downstream (P. Power, U.S. Fish and Wildlife Service, San Marcos, Texas, pers. comm.). Owens et al. (2001) reported a significant increase in dislodged plant fragments below high recreation use areas on the San Marcos River. Likewise, recreational activities were reported as significant in the uprooting of large masses of vegetation in Rainbow River (Mumma et al. 1996). The secluded stream harboring *Cryptocoryne* at Rainbow Springs Aquatic Preserve is currently restricted, but under consideration for public use.

ACKNOWLEDGMENTS

The author thanks the following individuals for their unique contributions: Pete Sleszynski granted site access and helped with sample collection; Michael E. Kane, Nancy L. Philman and A.E. Dudeck provided greenhouses for over-wintering; Niels Jacobsen, confirmed species identification with the photographs shown in Figures 1–3; Jan Bastmeijer kindly offered opinions on identification of Figures 1–3; Maria S. Sepulveda translated the abstract; Nancy C. Coile, R.E. Smith and David W. Hall reviewed versions of the manuscript; C.D.K. Cook provided insightful discussion; and W. Wayt Thomas confirmed *Rhynchospora colorata*.

NEPHROLEPIS EXALTATA (DRYOPTERIDACEAE) NEW TO ARKANSAS

James H. Peck

Department of Biology
University of Arkansas at Little Rock
2801 S. University Ave.
Little Rock, AR 72204, U.S.A.

ABSTRACT

Nephrolepis exaltata (Dryopteridaceae) is reported as new to Arkansas.

RESUMEN

Nephrolepis exaltata (Dryopteridaceae) se cita como nueva de Arkansas.

Nephrolepis Schott, the Sword Fern genus, consists of 25–30 species, mainly tropical in range, and is sometimes considered to be a small, monomorphic family (Kramer 1990). The genus name is from the Greek, meaning "kidney" and "scale," referring to the shape of the indusium. Species of this genus have given rise to many common cultivars that are excellent plants for growing on porches or other shaded locations outdoors in southeastern United States (Benedict 1916; Sessions 1978; Hoshizaki & Moran 2001). Four species and one hybrid are known to occur outside of cultivation in North America north of Mexico (Nauman 1993).

Native to southern one-half of peninsular Florida, *Nephrolepis exaltata* (L.) Schott has been extensively horticulturally selected and marketed as "Boston Fern". It is widely cultivated outdoors in the South. The specific epithet is from Latin, meaning "raised on high" or "lofty," referring to the perched site typically occupied in swamps. Its native range includes Florida, the West Indies and in scattered locations in the Pacific Islands, probably introduced, escaping, and becoming naturalized in many places. All populations in North America beyond Florida originated as escapes from cultivation from spores or abandoned plants. The species has escaped from cultivation and naturalized in peninsular Florida (Nauman 1981; Nauman et al. 2000), Orleans Parish, Louisiana (Thieret 1980), and Highland Park, Texas (pers. comm., G. Gibbs). In Arkansas it is a common horticultural or cultivated summer plant in every county in the state, with some winter-hardiness evident in the southernmost tier of counties.

Nephrolepis exaltata was first found in the wild in Arkansas on 25 September 2001 in natural woods east of Pine Bluff near the Arkansas River in Jefferson Co. One plant well mired in a mucky soil was found with 20 sterile fronds, obviously more than one year in age. The plant may have originated as the result

SIDA 20(2): 833–835. 2002

of escaped spores or more likely from plants abandoned in some manner. The park area accumulates flotsam and jetsam from the Arkansas River at high water levels. Stranded debris, plastic cemetery decorations, and other fluvially deposited materials attest to the efficacy of this mechanism. The plant will be monitored for persistence, production of spores, and reproduction of new plants.

This is the sixth non-native fern of the Arkansas pteridophyte flora of 97. The other exotics are *Lygodium japonicum*, *Macrothelypteris torressiana*, *Ophioglossum petiolatum*, *Psilotum nudum* (in part), *Pteris multifida*, and *Salvinia minima*. Only the *Lygodium* shows any ecological activity to be considered as an invasive species. Until this single plant *Nephrolepis exaltata* demonstrates reproductive competence, it will best be regarded as a waif. Additional populations are expected from time to time in the southern part of state following a few years with mild winters. (It seems unlikely that they would survive an extremely hard winter.)

This first report for this genus and species in Arkansas is surprising late in coming in that this and other horticultural-cultivated sword ferns are grown extensively across the state. Apparently, they have not escaped or become routinely established mainly because of the prolonged heat and drought of late summer in Arkansas.

The Arkansas vernacular name is "Yankee Fern," reputed to be a gentle retaliation for the renaming of *Dryopteris Xaustralis* or Southern Log Fern by some Connecticut Yankees who placed that hybrid into the horticultural trade through tissue culture under the market name of Dixie Fern.

Voucher Specimen: **ARKANSAS: Jefferson Co.:** Wet riparian woods SE of Trulock Campground, off access road to Atkins Lake-Nobel Lake along Arkansas River, 10 mi E of Pine Bluff, T6S R7W S5, *Peck 2001388* (LRU).

From Sinauer website (*www.sinauer.com*): "... the new edition incorporates all the important new developments in plant physiology, especially in cell, molecular, and developmental biology."

CYNOSURUS ECHINATUS (POACEAE) NEW TO TEXAS

R. Dale Thomas

Department of Biology
University of Louisiana at Monroe
Monroe, LA 71209, U.S.A.

Cynosurus echinatus L.—**TEXAS. Walker Co.:** Ebenezer Cemetery beside Hwy 30, 1 mi E of Farm Rd 2550, W of Huntsville, 30 May 1992, *R.D. Thomas 129,383* (BRIT, NLU).

The species has been reported from Oklahoma, Louisiana, Missouri, Arkansas, and many states of the eastern United States (Kartesz 1999). It also occurs in the Pacific coast states of California, Oregon, and Washington, and in British Columbia. Its closest known locality to the Walker County, Texas, site is in Caddo Parish, Louisiana (Thomas & Allen 1993). No plants of this species were relocated in a search of the Walker County site in June 1997 (pers. comm., Guy Nesom).

Cynosurus echinatus is native to southern Europe (Tutin 1980) and Africa, and Asia (Yatskievych 1999), but it is now established in North America, South America, and Australia. It is annual in duration and a colonizer of open disturbed sites, including fields, roadsides, and railways. Among various common names are "Hedgehog Dogtail," "Rough Dog's Tail," and "Bristly Dog's Tail Grass." A photograph is posted on the internet at <http://plants.montara.com / ListPages/FamPages/ Poa3.html#cynech>. Detailed line drawings are found at <http://biodiversity.uno.edu/ delta/grass/www/cynosuru.htm>.

ADDITIONS TO THE FLORA OF NAGS HEAD WOODS (DARE COUNTY, NORTH CAROLINA) AND THE OUTER BANKS OF NORTH CAROLINA

Alexander Krings

Herbarium, Department of Botany
North Carolina State University
Raleigh, NC 27695-7612
Alexander_Krings@ncsu.edu

ABSTRACT

Including an extensive system of dunes, interdunal ponds, and wetlands, the Nags Head Woods Ecological Preserve (Dare Co., North Carolina) comprises one of the best remaining examples of mid-Atlantic maritime deciduous forests. This study presents additions to the flora of the preserve and the larger Outer Banks, based on recent collections. Thirty-four taxa have not previously been reported for the preserve, five have not been reported for the Outer Banks, and two have been rediscovered.

RESUMEN

La Nags Head Woods Ecological Preserve (Dare Co., North Carolina), que incluye un sistema extensivo de dunas, lagunas interdunares, y humedales, comprende uno de los mejores ejemplos restantes de bosques caducifolios marítimos atlánticos. Este estudio presenta adiciones a la flora de la reserva y los mayores Outer Banks, basado en colecciones recientes. Treinta y cuatro taxa no habían sido citados previamente de la reserva, cinco no habían sido citados de los Outer Banks, y dos han sido redescubiertos.

The Nags Head Woods Ecological Preserve (Kill Devil Hills, Dare Co.) comprises one of the best remaining examples of mid-Atlantic maritime deciduous forest (Schafale & Weakley 1990) and includes an extensive system of dunes, interdunal ponds, and wetlands. Recent progress toward a flora of the preserve provided a checklist of vouchered collections housed at the herbarium of the National Park Service Cape Hatteras National Seashore Unit (CAHA), Manteo, North Carolina (Krings 2002). Although not listed in either the *Index Herbariorum* (Holmgren et al. 1990) or Aulbach-Smith et al. (1986), CAHA constitutes a valuable resource of North Carolina barrier island collections. The collections from the Nags Head Woods Ecological Preserve (NHWEP) housed at CAHA include material collected by various members of the Dunes of Dare Garden Club, McCaffrey, as well as Stalter and Lamont (1997). This study presents new additions to the flora of the preserve and the larger Outer Banks (sensu Stalter & Lamont 1997), resulting from recent collections by the author and preserve staff.

METHODS

The list was compiled based on field collections by the author and preserve

SIDA 20(2): 839–843. 2002

staff over the period of Mar 2001–Sept 2002. Specimens were critically studied and identified at the herbarium of North Carolina State University (NCSC).

RESULTS

Species at the NHWEP listed below include new additions to the flora, as well as species previously reported but not vouchered by Blonder and Stalter (1992) or Stalter and Lamont (1997). Asterisks preceding a scientific name indicate that taxon to be a new addition to the flora of NHWEP (i.e., not previously reported by Blonder and Stalter (1992) or not specifically reported for the preserve by Stalter and Lamont (1997)).

The list includes 89 species, 34 (38%) of which have not been previously reported for the preserve, and 5 (~6%) of which have not been reported for the Outer Banks (i.e., not listed in either Burk (1961), Blonder and Stalter (1992), or Stalter and Lamont (1997)).

Pteridophyta

ASPLENIACEAE

**Asplenium platyneuron* (L.) BSP., *Krings 450* (NCSC)

OSMUNDACEAE

Osmunda cinnamomea L., *Krings 534* (NCSC)

Osmunda regalis L. var. *spectabilis* (Willd.) A. Gray, *Krings 538* (NCSC)

Gymnospermae

CUPRESSACEAE

Juniperus virginiana L., *Krings 373* (NCSC)

PINACEAE

Pinus palustris Mill., *Krings 563* (NCSC)

Pinus taeda L., *Krings 564* (NCSC)

TAXODIACEAE

Taxodium distichum (L.) Rich., *McCall s.n.* (NCSC)

RUBIACEAE

Cephalanthus occidentalis L., *Krings 410* (NCSC)

Galium hispidulum Michx., *Krings 370* (NCSC)

**Galium obtusum* Bigelow, *Krings 519* (NCSC)

Mitchella repens L., *Krings 484* (NCSC)

SALICACEAE

Salix caroliniana Michx., *Krings 539* (NCSC)

SAURURACEAE

Saururus cernuus L., *Krings 405* (NCSC)

SCROPHULARIACEAE

**Bacopa monnieri* (L.) Pennell, *Krings 528* (NCSC)

**Linaria canadensis* (L.) Dum. Cours., *McCall s.n.* (NCSC)

SOLANACEAE

**Physalis walteri* Nutt., *Krings 524* (NCSC)

VERBENACEAE

Callicarpa americana L., *Krings 411* (NCSC)

VIOLACEAE

**Viola sororia* Willd., *Paris s.n.* (NCSC)

VITACEAE

Ampelopsis arborea (L.) Koehne, *Krings 407* (NCSC)

Parthenocissus quinquefolia (L.) Planch., *Krings 468* (NCSC)

DISCUSSION

Table 1 lists species apparently discovered for the first time from the Outer Banks or rediscovered after not having been seen by Stalter and Lamont (1997). The find of *Aristolochia serpentaria* (Aristolochiaceae) is rather interesting, although not altogether surprising as it is generally associated with mixed deciduous forests (Radford et al. 1968). As few examples of maritime deciduous forests remain in North Carolina, the species likely remains rare due to habitat availability on the Outer Banks. Although relatively common in the North Carolina Coastal Plain, *Tragia urens* has been previously reported for the Outer Banks only by Burk (1961). Stalter and Lamont (1997) did not mention the taxon and presumably did not observe it. It remains unknown whether the taxon persists on Bogue Banks as reported by Burk (1961). *Celastrus orbiculatus* and *Pueraria lobata* var. *montana* have been weeds of concern to the preserve staff and efforts are underway to severely control, if not eradicate, them from the site.

ACKNOWLEDGMENTS

I thank the Nature Conservancy for access to the preserve and Aaron McCall, Rhana Paris, and Jeff DeBlieu for thoughtful conversations and collection help.

ABSTRACT

Cirsium nuttallii (Asteraceae) is documented for North Carolina. The species had previously been known from Florida to South Carolina and from disjunct populations in Virginia. An illustrated key is provided to aid others in the diagnosis of *Cirsium* in North Carolina and the southeast.

RESUMEN

Se documenta *Cirsium nuttallii* (Asteraceae) para el estado de Carolina del Norte. Previamente se conocía la especie sólo desde Florida a Carolina del Sur y de poblaciones disyuntas en Virginia. Se presenta una clave ilustrada para ayudar los demás en las diagnosis de *Cirsium* en el sudeste.

A southeastern United States endemic, *Cirsium nuttallii* DC. (Asteraceae: Cynareae) has been previously known only from peninsular Florida to Louisiana and South Carolina, and from apparently disjunct populations in southeastern Virginia (Radford et al. 1968, Cronquist 1980). However, recently Randy Westbrooks found an individual in a pasture in Whiteville, Columbus Co., North Carolina. When surveyed, the plant was about 2.4 m tall. Apparently, it had not been seen in the pasture previously. Additional survey by Robert Eplee located a population lightly scattered over 10 acres, north of Hallsboro (also Columbus Co.). The species is known from at least 16 counties in South Carolina, including nearby Marion Co. North Carolina now includes all 12 species of native and naturalized *Cirsium* known from the southeast. Voucher specimens of *C. nuttallii* were prepared for deposit at NCSC, OBI, and US.

Voucher specimen: U.S.A. **NORTH CAROLINA. Columbus Co.:** Whiteville, in a pasture, roughly 8 ft tall, 24 Jun 2002, *R. Westbrooks s.n.* (NCSC, OBI, US).

Cirsium nuttallii DC. (Fig. 1H) is one of the tallest *Cirsium* species in the southeast, capable of attaining heights of 3.5 m (Cronquist 1980). Only *Cirsium altissimum* (L.) Sprengel and *C. discolor* (Muhl.) Sprengel are known to grow to

a similar maximum size (Cronquist 1980). These latter two can be distinguished from *C. nuttallii* by the abaxial leaf surface densely and persistently white tomentose (arachnoid-tomentose to glabrate in age in *C. nuttallii*).

Cirsium nuttallii can be distinguished from its southeastern congeners by the combination of the following traits: (1) plant biennial, 1.5–3.5 m tall, (2) stems not winged, but branched and many-headed, (3) abaxial leaf surface arachnoid-tomentose to glabrate in age, (4) involucres 1.5–2.5 cm long, and (5) middle and outer involucral bracts with a glutinous adaxial ridge and tipped by spines 1–2(–3) mm long. We are providing a key, largely adapted from Cronquist (1980), as well as illustrations in hopes they might prove of diagnostic use to others.

KEY TO *CIRSIUM* IN THE SOUTHEASTERN UNITED STATES

1. Stems conspicuously winged by spiny, decurrent leaf bases (Fig. 1A, i), the wings nearly or as long as the internodes _____ **Cirsium vulgare** (Savi) Ten. (Fig. 1A, ii)
1. Stems not winged by decurrent leaf bases.
   2. Heads conspicuously and closely subtended by a series of narrow, reduced, strongly spiny leaves (Fig. 1C) _____ **Cirsium horridulum** Michx.
   2. Heads not closely subtended by a series of reduced spiny leaves.
      3. Plant colonial, perennial (by creeping roots); polygamo dioecious, the heads nearly unisexual with the pappus of the pistillate head longer than the corresponding corollas and the pappus of the staminate heads shorter than the corresponding corollas (Fig. 1D, i & ii) _____ **Cirsium arvense** (L.) Scop.
      3. Plant not colonial, biennial or perennial; heads all similar and perfect.
         4. Involucral bracts completely lacking spiny tips or only exhibiting a vestigial spinule to 0.5 mm long (Fig. 1B) _____ **Cirsium muticum** Michx.
         4. Involucral bracts bearing spiny tips, the spines typically at least 1 mm long.
            5. Abaxial leaf surface densely and persistently white-tomentose.
               6. Plants robust, 1–3(–4) m tall; largest lobed leaves generally > 5 cm wide; involucres generally 2.5–3.5 cm long
                  7. Leaves deeply pinnatifid (Fig. 1F, i) _____ **Cirsium discolor** (Muhl. ex Willd.) Sprengel (Fig. 1F, ii)
                  7. Leaves toothed or shallowly lobed _____ **Cirsium altissimum** (L.) Sprengel (Fig. 1K)
               6. Plants relatively slender, 0.5–1.5 m tall; largest lobed leaves generally < 5 cm wide; involucres generally 1.5–2.5 cm long
                  8. Cauline leaves mostly 30–70; plants flowering in Aug–Oct; savannahs, bogs, and wet pinelands _____ **Cirsium virginianum** (L.) Michx. (Fig. 1E)
                  8. Cauline leaves mostly 10–25; plants flowering Apr–Jun; open woods and dry, sandy soil _____ **Cirsium carolinianum** (Walt.) Fern. & Schub. (Fig. 1G)
            5. Abaxial leaf surface arachnoid-villous (sometime sparsely so) to glabrate (particularly in age).
               9. Plants 1.5–3.5 m tall, branched and many-headed; involucres 1.5–2.5 cm long (Fig. 1H) _____ **Cirsium nuttallii** DC.
               9. Plants 0.2–1 m tall, unbranched or only sparingly branched; involucres 2.5–5 cm long.
                  10. Young stems and abaxial leaf surfaces thinly and loosely white

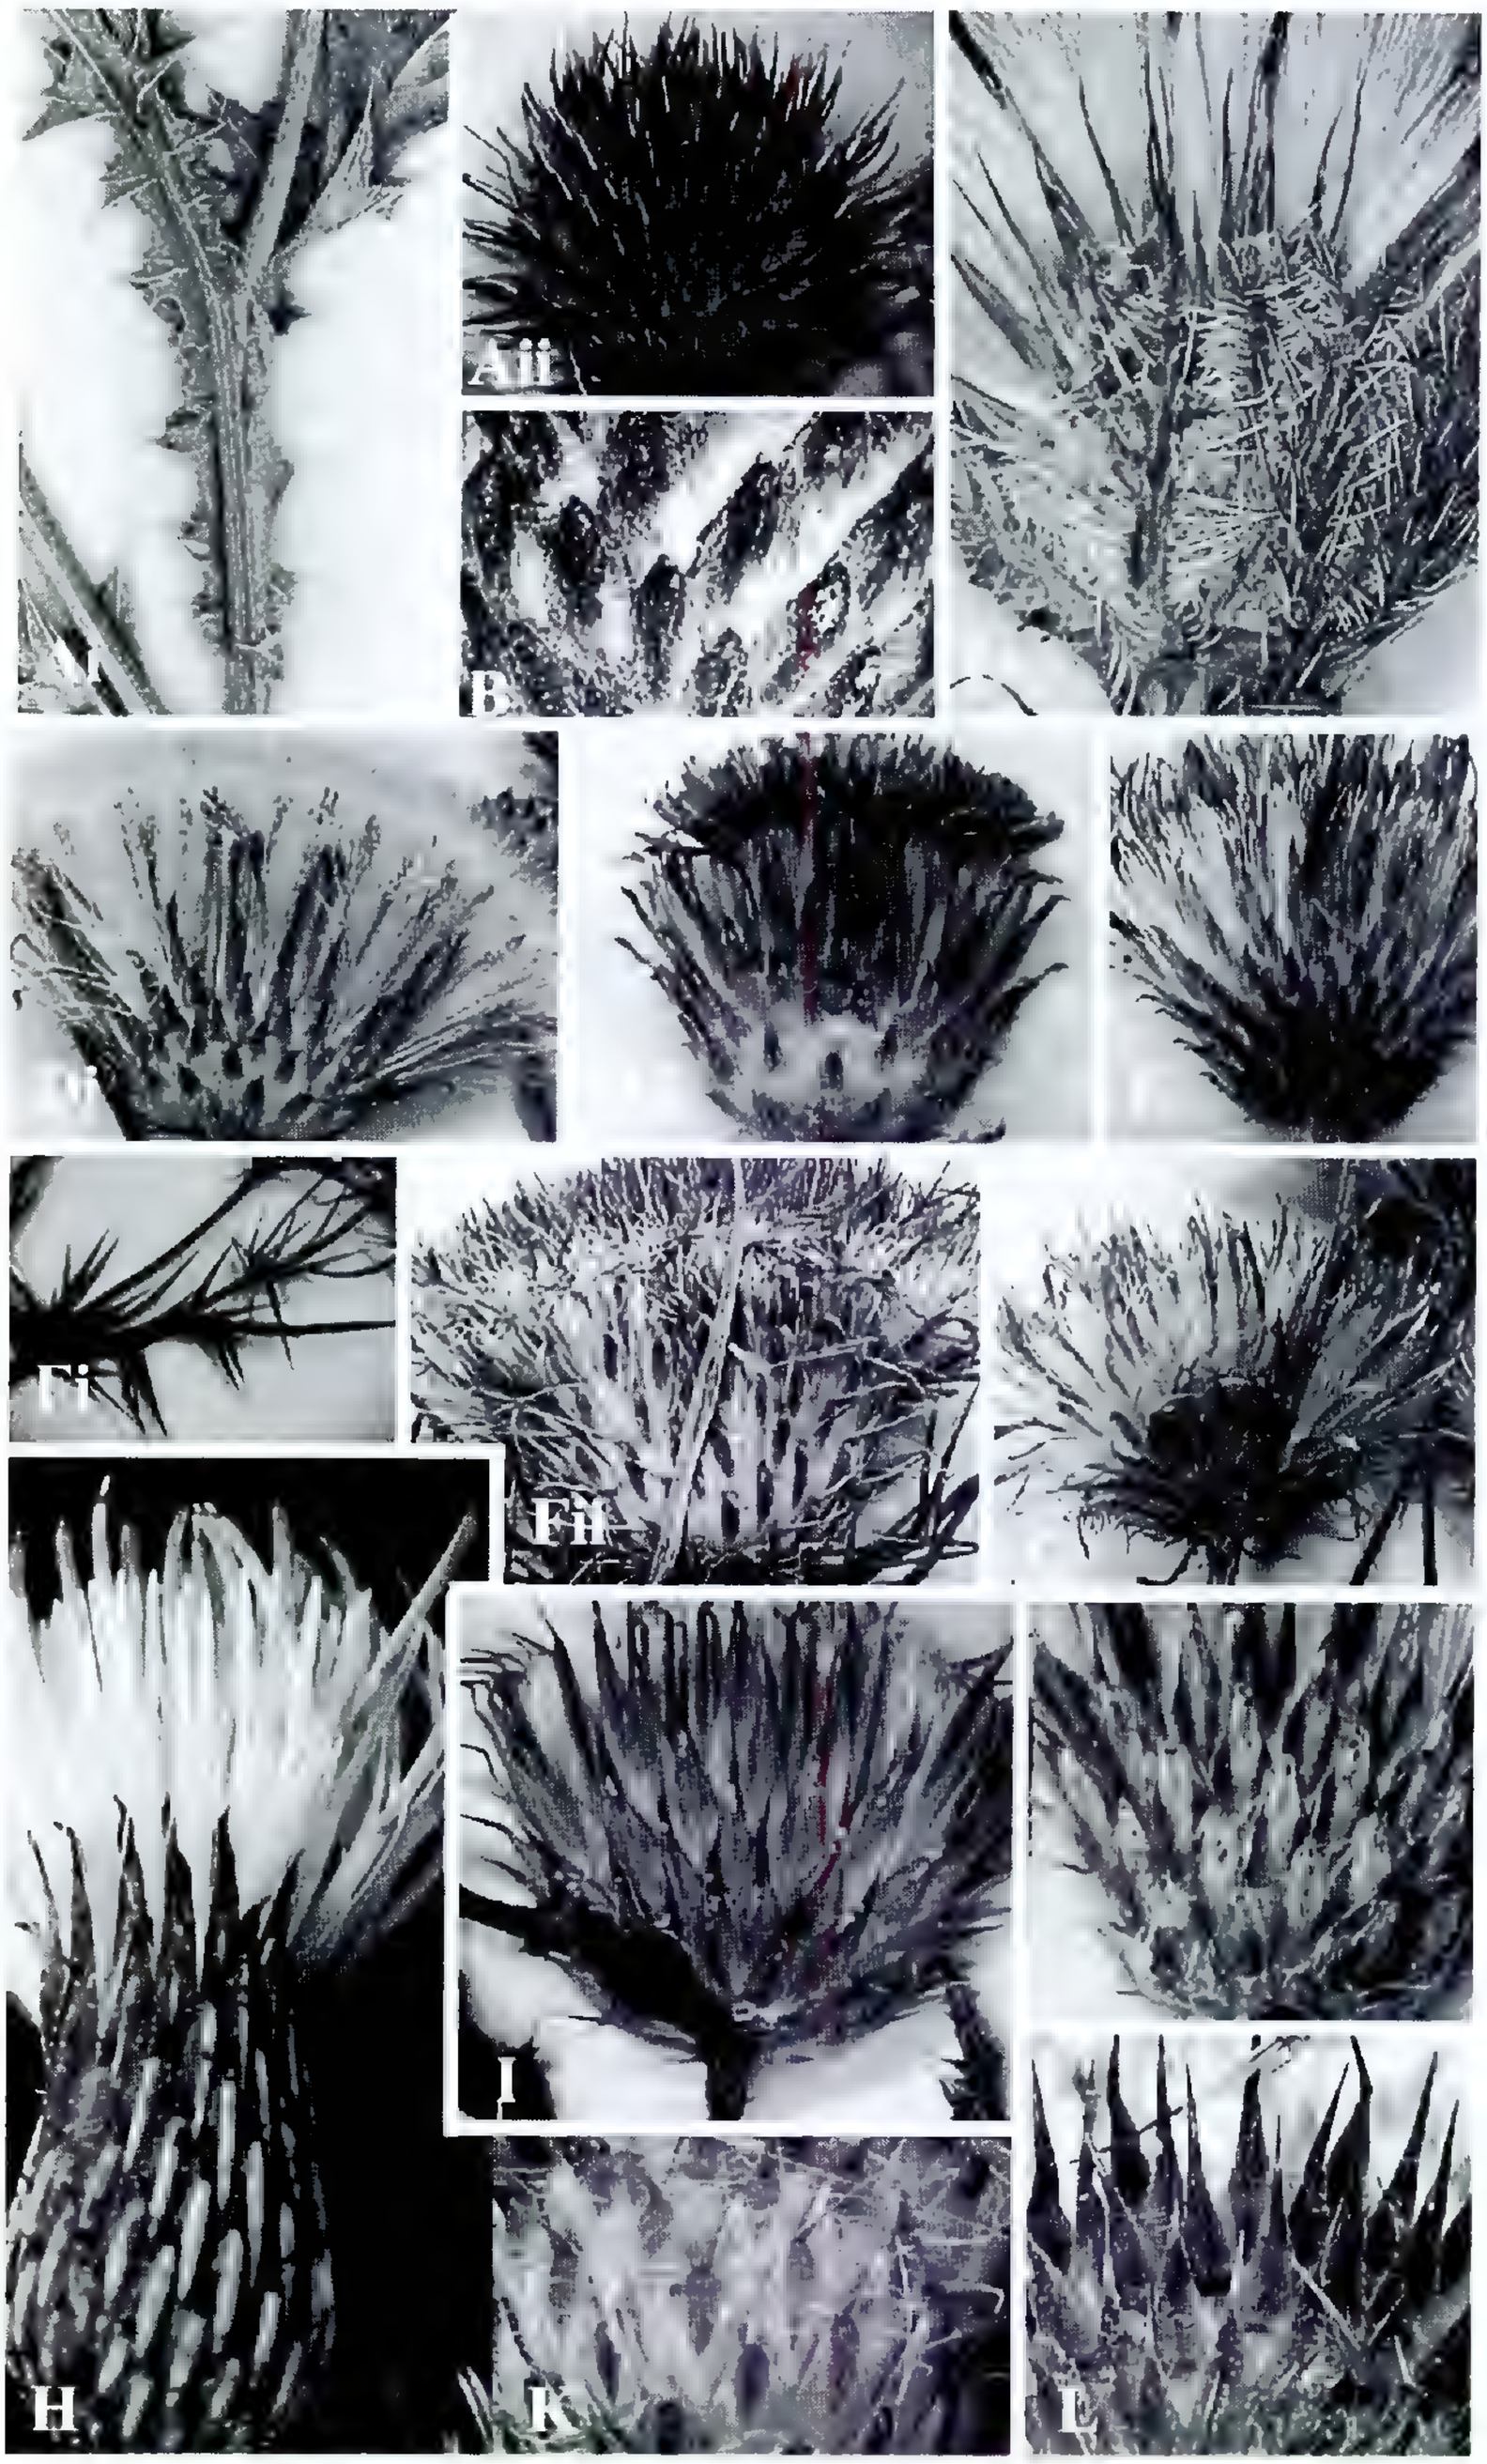

FIG. 1. Southeastern *Cirsium* (Asteraceae): **A,** *Cirsium vulgare* – i, stems winged from decurrent leaves; ii, involucre (*Biltmore Herbarium 168b*); **B,** *Cirsium muticum* involucre (*Whitford s.n.*); **C,** *Cirsium horridulum*, with reduced leaves crowded around involucre (*Veerhoff 346*); **D,** *Cirsium arvense* – i, pistillate flower, note long pappus; ii, staminate flower, note pappus shorter than corollas (*Eames s.n.*); **E,** *Cirsium virginianum* involucre (*Godfrey & Fox 51040*); **F,** *Cirsium discolor* – i, deeply pinnatifid leaves; ii, involucre (*Wilbur 4856*); **G,** *Cirsium carolinianum* involucre (*Godfrey & Fox 50388*); **H,** *Cirsium nuttallii* involucre, note dorsal, elongate glutinous ridge on bracts (*R. Westbrooks s.n.*); **I,** *Cirsium lecontei* involucre (*Blair 759*); **J,** *Cirsium repandum* involucre (*Fox 1693*); **K,** *Cirsium altissimum* involucre (Nicholson s.n.); **L,** *Cirsium pumilum* involucre (*Fox 3687*). All specimens from NCSC.

tomentose, older stems and abaxial leaf surfaces glabrate; heads strongly pedunculate _____ **Cirsium lecontei** Torr. & A. Gray (Fig. 1I)

10. Young stems and abaxial leaf surfaces arachnoid-villous, hirsute, or rarely arachnoid tomentose; heads scarcely or more or less strongly pedunculate.
    11. Cauline leaves crowded, the internodes frequently < 1 cm long; inner involucral bracts gradually tapering to a narrowly pointed tip (Fig. 1J) _____ **Cirsium repandum** Michx.
    11. Cauline leaves typically not crowded (although sometimes so near the base); inner involucral bracts with expanded, chartaceous, crisped, and erose tips (Fig. 1L) _____ **Cirsium pumilum** (Nutt.) Spreng.

REINSTATEMENT OF *VIBURNUM OZARKENSE* (CAPRIFOLIACEAE): AN ENDEMIC TAXON OF THE INTERIOR HIGHLANDS OF ARKANSAS, MISSOURI AND OKLAHOMA

Timothy J. Weckman

Department of Biological Sciences
Eastern Kentucky University
Richmond, KY 40475, U.S.A.

ABSTRACT

Based on field work and morphological analysis of herbarium specimens, *Viburnum ozarkense* Ashe is reinstated as a distinct species. Recognition of the occurrence and distribution of *V. ozarkense* has been compromised by its reduction to synonymy under *Viburnum molle* Michx. A morphological characterization of *V. ozarkense* and *V. molle*, a key to species, and a distribution map are provided. This research supports the recognition of *V. ozarkense* as an endemic shrub of the Interior Highlands of Arkansas, Missouri and Oklahoma.

RESUMEN

Basados en trabajo de campo y análisis morfológico de especímenes de herbario, *Viburnum ozarkense* Ashe se repone como una especie distinta. El reconocimiento de la ocurrencia y distribución de *V. ozarkense* ha estado comprometido por su reducción a sinónimo de *Viburnum molle* Michx. Se ofrecen una caracterización morfológica de *V. ozarkense* y *V. molle*, una clave de especies, y un mapa de distribución. Esta investigación apoya el reconocimiento de *V. ozarkense* como un arbusto endémico de las montañas Ouachita y Ozark de Arkansas, Missouri y Oklahoma.

INTRODUCTION

Viburnum ozarkense was described from material W. W. Ashe collected in Stone County, Arkansas with the type locality providing the only distributional reference (Ashe 1928). Ashe was a prolific collector, amassing some 30,000 specimens by his death (Massey 2001). Ashe also published 510 species and varietal names from these collections, but many have been reduced to synonymy (Coker et al. 1932). *Viburnum molle* was described by Michaux from material he collected in Kentucky in the late 1700s (Michaux 1803). Ashe was aware of *V. molle* Michx., and provided characteristics to separate *V. ozarkense* from *V. molle* in his species description. Original material from both of these collections has not been readily accessible to American botanists: the Michaux collection of *V. molle* was deposited in the Paris herbarium (P)(acronyms after Holmgren et al. 1990), and most of Ashe's collections were inaccessible in his private herbaria at the time of his death (Coker et al. 1932).

The name *V. ozarkense* was retained in an early checklist for Arkansas (Moore 1941) and in a generic treatment of *Viburnum* by McAtee (1956). How-

ever, it was reduced to synonymy under *V. molle* Michx. by Steyermark (1963) and this placement has been followed by current treatments (Tucker 1976; Smith 1988; USDA, NRCS 2002). Neither taxon is currently monitored by heritage programs in Arkansas, Missouri or Oklahoma. Based on morphological analysis of *Viburnum ozarkense* and *V. molle*, I recognize these taxa as distinct, provide a key to differentiate them, and map the current distribution of both taxa in Arkansas, Missouri and Oklahoma.

MATERIALS AND METHODS

Loans were requested from herbaria with Ashe collections: A, GH, ILL, L, LCU, MO, NCU, POM, and US, and certain herbaria having Arkansas, Missouri and Oklahoma *Viburnum* material: APCR, BRIT, NA, NYBG, OKL, SMS, UAM, UARK, and UMO. Additional specimens were collected during field work in Arkansas, Missouri and Oklahoma in 1999–2001.

Measurements were recorded for 14 quantitative characteristics: leaf size, toothing, venation, length of leaf tip, petiole length on fertile and vegetative shoots, peduncle length, number of rays, inflorescence width and height, corolla width, stamen length and fruit length and width. Qualitative characteristics including leaf shape, leaf and petiole pubescence, the presence, placement and pubescence on stipules and inflorescence bracts, flowering times and shoot pubescence and color were noted. Mensural and qualitative data were used to prepare a diagnostic key for the species.

Habitat and associate information was gleaned from vouchers and from field work. A distribution map of all known populations of *V. ozarkense* and *V. molle* occurring in Arkansas, Missouri and Oklahoma was prepared from annotated loans and new collections.

RESULTS AND DISCUSSION

Loans resulted in 236 vouchers for study. An additional 119 collections were produced from field work during 1999–2001 in Arkansas, Missouri and Oklahoma. Of these, 193 were referable to *Viburnum ozarkense* and 162 to *V. molle*. They are all listed in the specimens examined section for each taxon.

Mensural results

Mensural analysis indicates that the most useful features for differentiating *Viburnum ozarkense* from *V. molle* are leaf width, number of teeth per half leaf, number of veins per half leaf, leaf tip length, petiole length below an inflorescence or at the apex of a vegetative shoot, corolla width and fruit length. The means of these characters were all statistically significantly different (Table 1). Measured features not significantly different between the species were leaf length, peduncle length, inflorescence width and height, stamen length and fruit width.

Based on my measurements leaves in *Viburnum ozarkense* averaged 7.2 cm wide, with 5.3 veins and 13.9 teeth per half leaf, and had an acuminate apex averaging 7.7 mm long. Leaves of *V. molle* were wider, averaging 8.2 cm broad, with 6.1 veins; more toothed, averaging 25.6 teeth per half leaf; and with an acute apex averaging 2.9 mm long. *Viburnum ozarkense* petioles on both flowering and sterile shoots are shorter than those of *V. molle*. The first petioles below an inflorescence averaged 1.1 cm in *V. ozarkense* and 2.4 cm for *V. molle*. Petioles on the distal ends of vegetative shoots are similarly shorter on *V. ozarkense* shoots ($\bar{x}$= 2.1 cm) than *V. molle* shoots ($\bar{x}$= 3.4 cm). Corollas were significantly wider in *V. ozarkense* flowers ($\bar{x}$= 6.6 mm) than in *V. molle* flowers ($\bar{x}$= 4.4 mm), but these data were derived from a small sample (n= 40). Mature fruits were significantly longer in *V. ozarkense* ($\bar{x}$= 1.1 cm) than in *V. molle* ($\bar{x}$= 0.9 cm), but again, sample size was small (n= 41). Vegetative specimens of these taxa are differentiated based on the number of teeth per half leaf. This characteristic overlaps in only a few individuals with distinct peaks well separated (Fig. 1).

Qualitative characteristics

Qualitative features such as leaf shape, leaf and petiole pubescence, color of current year shoots and bark features also provided useful characteristics to separate the species (Table 1). In outline, *Viburnum molle* leaves are broadly ovate or orbicular; those of *V. ozarkense* are narrower and appear ovate in outline. Adaxial leaf surfaces of *V. ozarkense* are uniformly hirsute, with short hairs (ca. 0.25 mm long) across the surface. In contrast, adaxial surfaces of *V. molle* leaves are glabrous or may have a few scattered red, glandular hairs. Similarly, petioles of *V. ozarkense* are pubescent, covered with moderate to dense strigose and glandular hairs and an open furrow. Petioles of *V. molle* are essentially glabrous and any observed pubescence is typically manifested as a few glandular hairs at the distal end of the petiole or as a few villous hairs along the margin of the closed petiole furrow. Stipules are present in both species; in *V. molle* these occur in single pairs, while in *V. ozarkanse* two pairs of stipules per leaf stalk are often observed. In cross section, *V. ozarkense* petioles appear oval while *V. molle* petioles appear terete. The color of current year shoots at mid-season also provides a useful way to differentiate these taxa. For *V. ozarkense* they are reddish-brown, in contrast to the yellow-tan shoots of *V. molle*. The most obvious field character separating these viburnums is the presence of exfoliating bark persistent on stems after the second year of growth on *V. molle* shoots verses the tight bark throughout the branching of *V. ozarkense*. Although this is a prominent field character, it is not consistently present on herbarium sheets, as many collections do not show enough branch to capture it.

DIAGNOSTIC KEY

Leaves ovate, adaxially hirsute, 8 to 21 (mode 14) marginal teeth per half leaf; petioles of first pair of leaves below inflorescence $\bar{x}$= 1.0 cm, $\bar{x}$= 2.0 cm at tips of vegeta-

TABLE 1. Comparison of characteristics useful in differentiating *V. ozarkense* and *V. molle*. N = number of individuals measured or sampled. Data – range with means and standard deviations in parentheses. * = values significantly different at $p < .05$.

Phenology

Flowering material (about 5% each of *Viburnum molle* and *V. ozarkense* vouchers) for the plants that occurred in Arkansas, Missouri and Oklahoma indicated that *V. ozarkense* flowers earlier than *V. molle*. Based on the material I examined, *V. ozarkense* flowered between May 6 and June 7, with a peak flowering time of May 19. *Viburnum molle* flowered between May 15 and May 29, with a peak on May 27–29 (Fig. 2).

Habitat and Associates

Information gleaned from herbarium labels and field experience indicated that *Viburnum ozarkense* and *V. molle* occupied similar habitats and had a similar set of associates. Most associate data were compiled from field notes of the author.

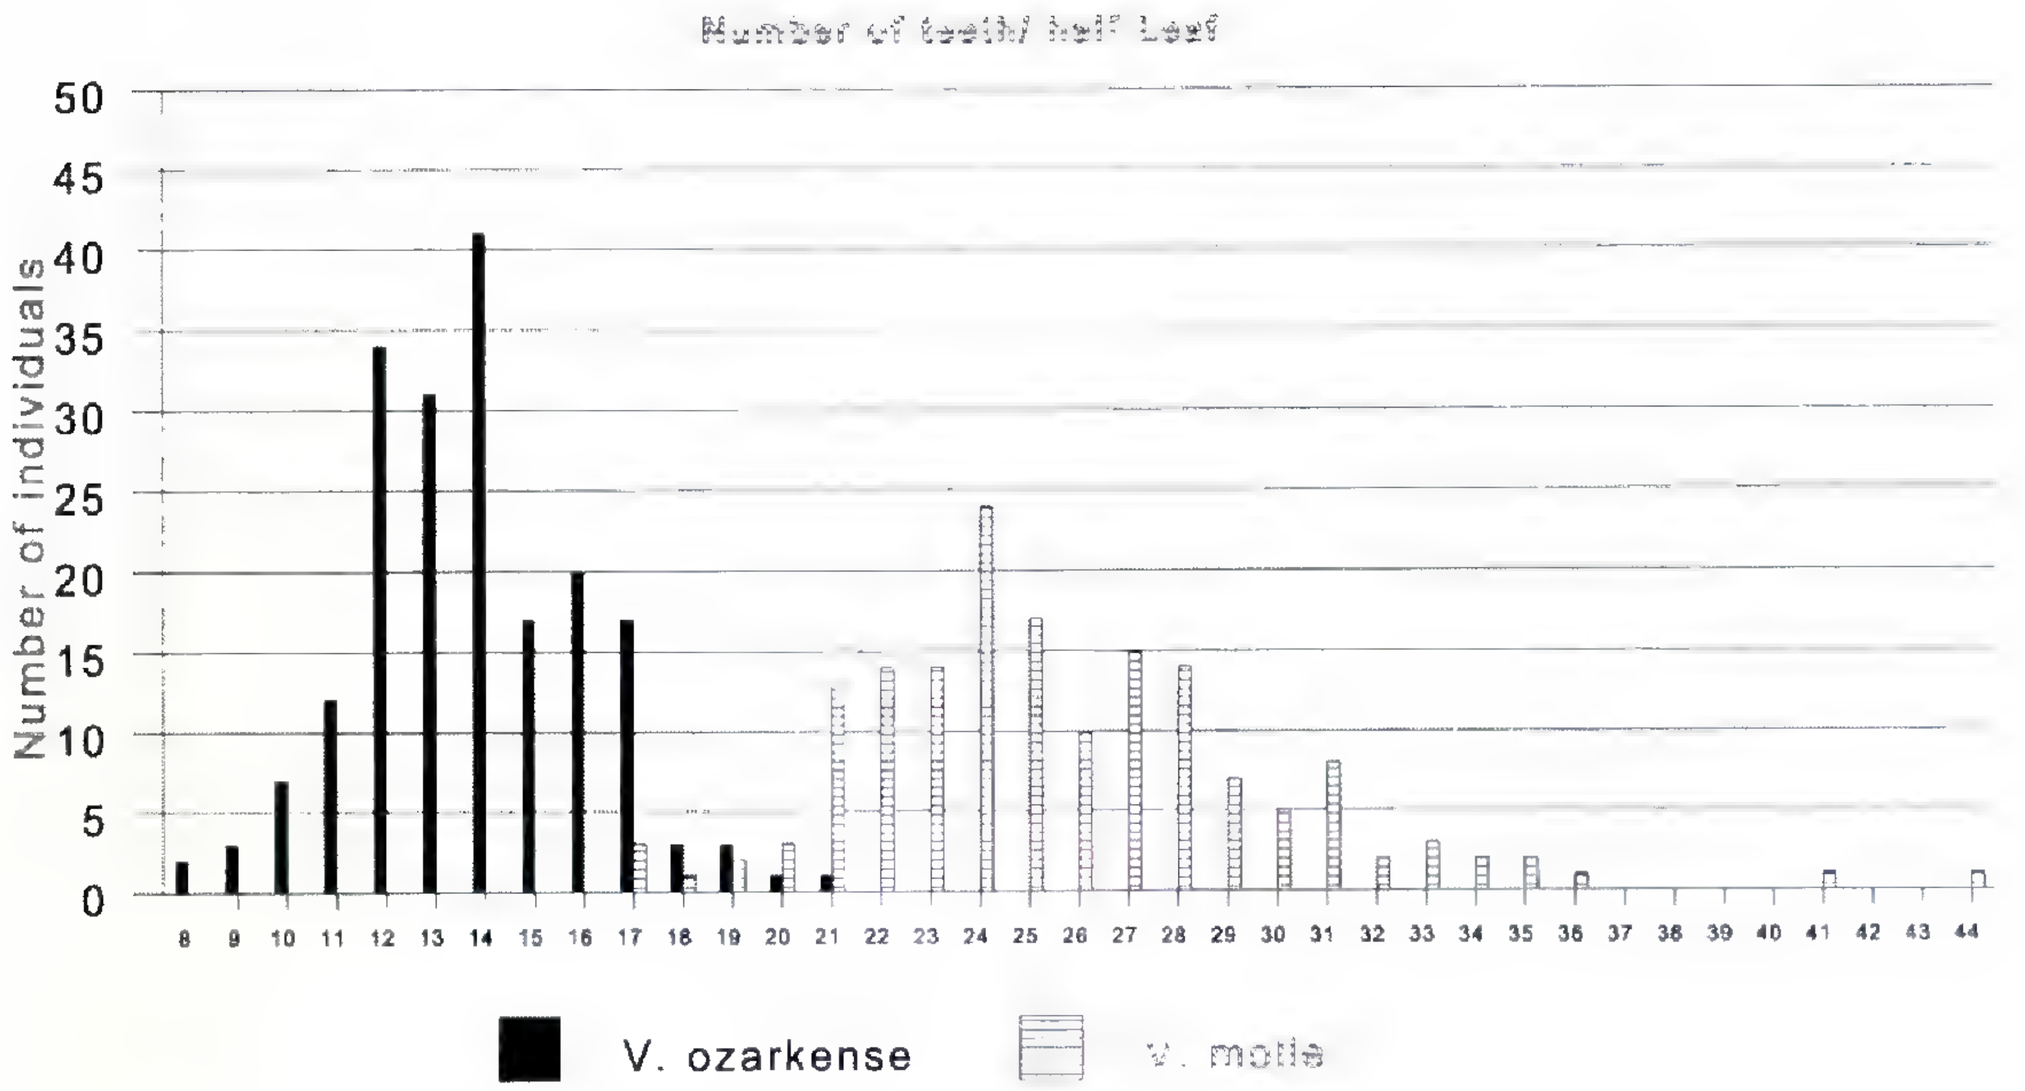

FIG. 1. Number of marginal teeth per half leaf for *Viburnum ozarkense* and *Viburnum molle* specimens collected in Arkansas, Missouri and Oklahoma.

Viburnum ozarkense

Populations of *Viburnum ozarkense* in Arkansas are most often encountered on north-facing ridges, rocky limestone hillsides and wooded slopes in rich woods. It also occurs on ledges and in rocky woods above and along creeks (ex. Alum Fork, Bard Springs, Buffalo River, Cap Fork, Little Red River and Stepp Creek). Associates of *V. ozarkense* in Arkansas include: *Acer saccharum, Arundinaria gigantea, Berchemia scandens, Carpinus caroliniana, Carya cordiformis, Chionanthus virginicus, Cornus florida, Diospyros virginiana, Dirca palustris, Hamamelis vernalis, Hydrangea arborescens, Magnolia acuminata, Philadelphus pubescens, Quercus muhlenbergii, Q. stellata, Rhamnus caroliniana, Rhus aromatica, Sideroxylon lanuginosum, Staphylea trifolia, Tilia americana, Vaccinium arboreum* and *Viburnum rufidulum.*

In Missouri, *Viburnum ozarkense* has been collected from north and northeast facing limestone ledges and bluffs above the Eleven Point River, from limestone slopes along Myatt Creek, and north facing limestone slopes along the South Fork of the Spring River. These are often mid-slope locations with filtered light. Associates of *V. ozarkense* in Missouri included: *Acer saccharum, Berchemia scandens, Carpinus caroliniana, Cornus florida, Fraxinus quadrangulata, Lindera benzoin, Ostrya virginiana, Quercus alba, Q. muhlenbergii, Q. rubra, Sideroxylon lanuginosum,* and *Viburnum rufidulum.*

In Oklahoma, *Viburnum ozarkense* has been collected from a rocky north facing chert slope above Caney Creek in Adair County, and wooded oak-pine hillsides in McCurtain County. Associates of *V. ozarkense* in Oklahoma at the

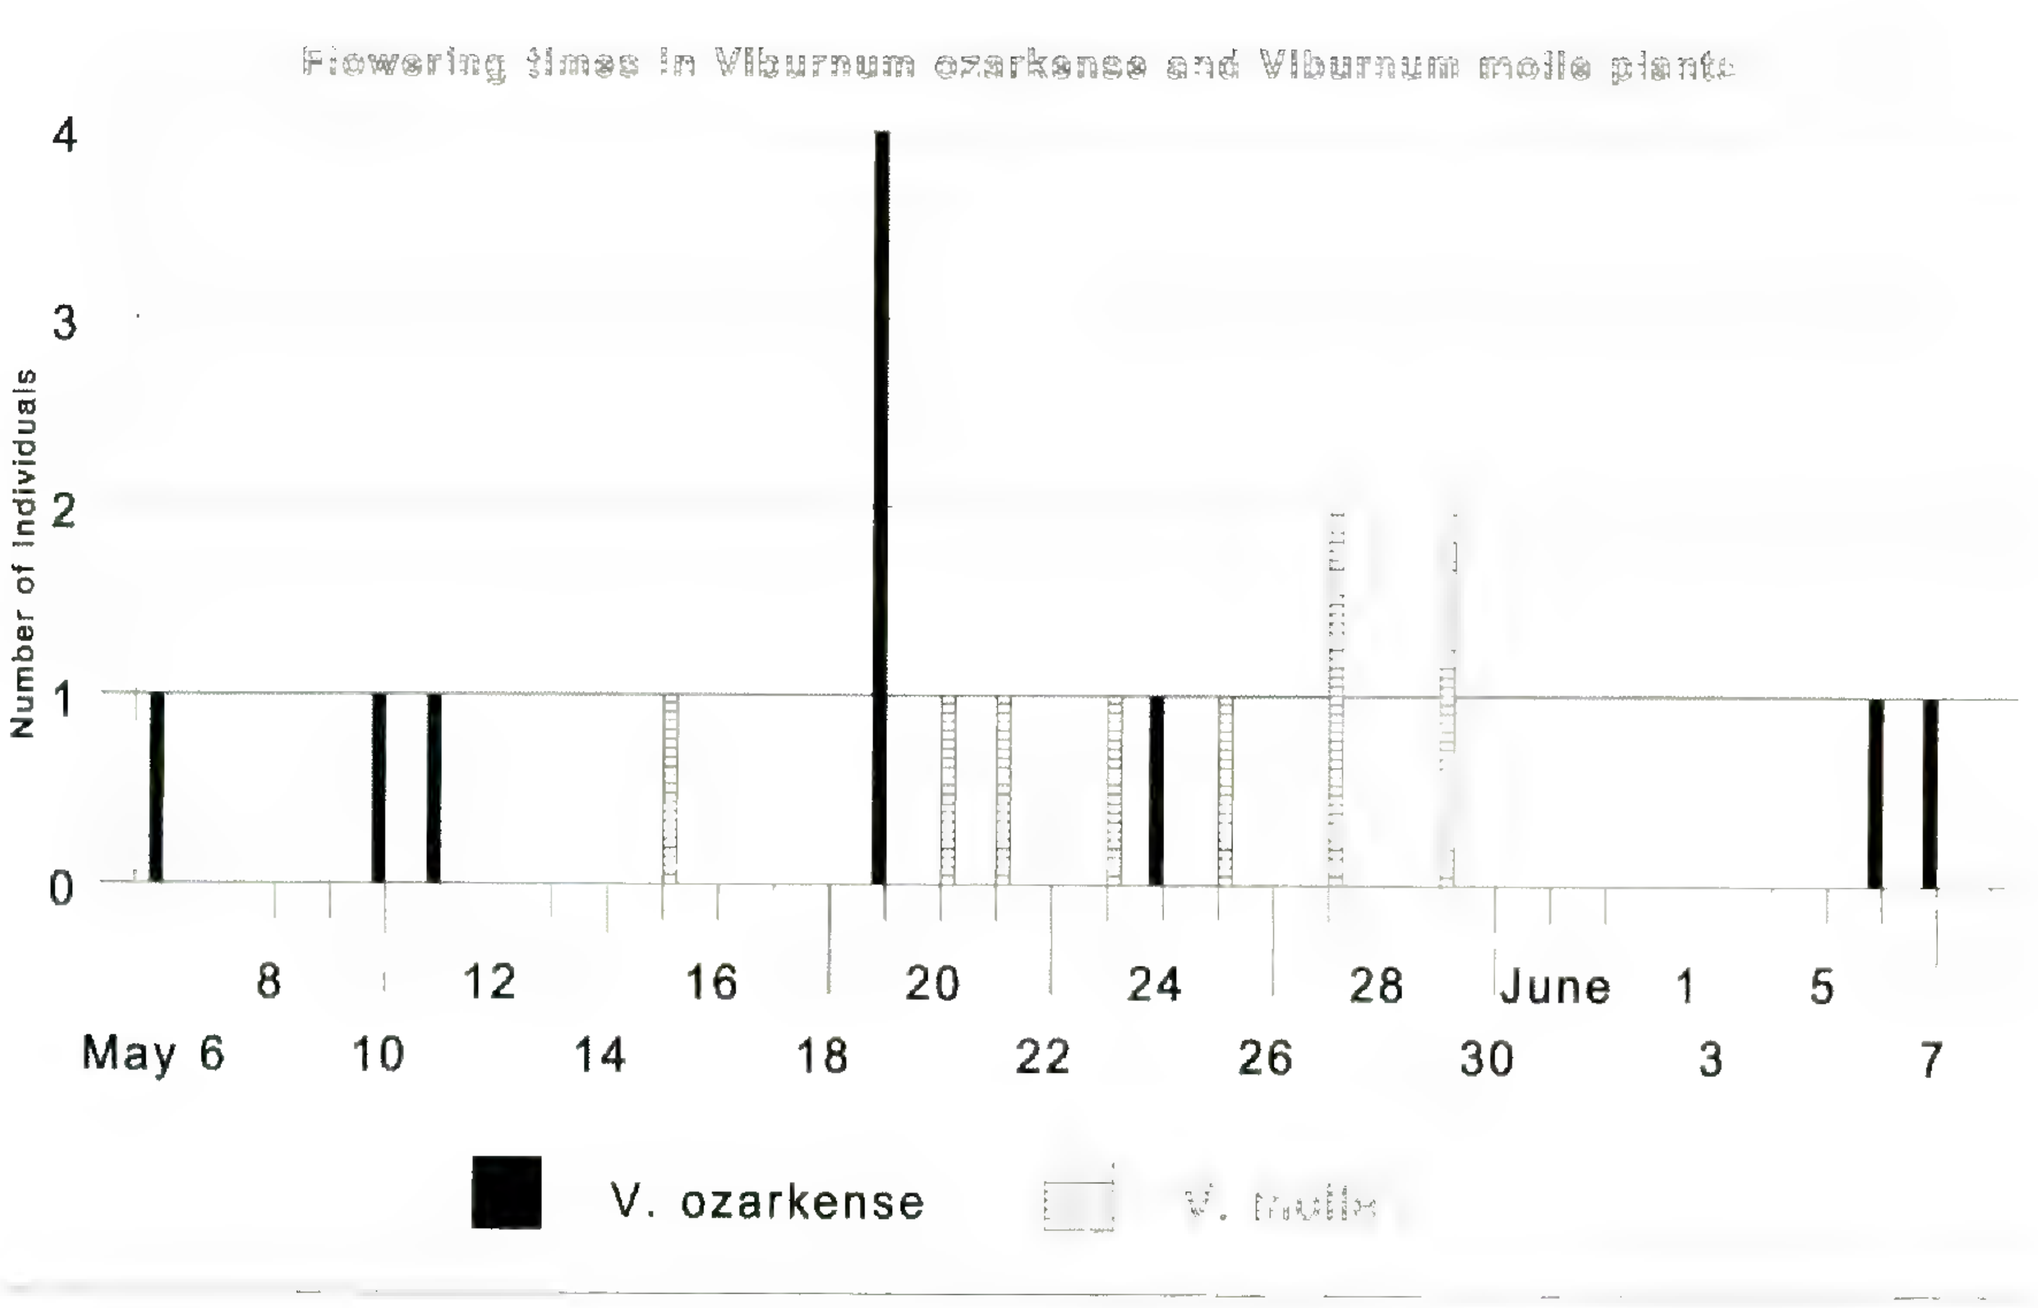

FIG. 2. Flowering phenology of *Viburnum ozarkense* and *Viburnum molle* in Arkansas, Missouri and Oklahoma.

Adair County site included: *Acer saccharum, A. rubrum, Asimina triloba, Cercis canadensis, Corylus americana, Hydrangea arborescens, Lindera benzoin, Nyssa sylvatica, Quercus alba, Sassafras albidum, Staphylea trifolia, Tilia americana* and *Viburnum rufidulum.*

Viburnum molle

Viburnum molle occurs in Arkansas on chert slopes at the base of north facing bluffs along War Eagle Creek in Madison County. A single collection by E.J. Palmer documented *V. molle* in Boone County from "rocky ledges, Harrison." Associates of *V. molle* in Arkansas at the War Eagle Creek site included: *Acer saccharum, Asimina triloba, Hydrangea arborescens, Juglans nigra, Lindera benzoin, Magnolia acuminata, Quercus muhlenbergii, Q. rubra, Staphylea trifolia,* and *Tilia americana.*

Habitats in Missouri which support *Viburnum molle* include north facing slopes, bluffs and limestone ledges along creeks and rivers (ex. Castor River, Cole Camp Creek, Gasconade River, Jacks Fork of Current River, James River, Jonca Creek, Lost Creek, Meramec River, Piney Creek, River Aux Vases, Stinson Creek, Swan Creek, West Fork Cuivre River). Along these creeks and rivers, *V. molle* plants typically occur as understory elements receiving filtered or part day sunlight, at the mid-slope point, neither in the floodplain nor at the more xeric ridge crest. In Missouri associates included: *Acer saccharum, Asimina triloba, Carpinus caroliniana, Cornus florida, Dirca palustris, Juniperus*

virginiana, *Quercus muhlenbergii*, *Sideroxylon lanuginosum*, *Tilia americana*, and *Viburnum rufidulum*.

Viburnum molle is not known to occur in Oklahoma.

Distribution and rarity

Distribution of *Viburnum ozarkense* was compiled from annotated herbarium vouchers and new collections produced for this study (Fig. 3). *Viburnum ozarkense* is confined to the Ouachita and Boston Mountains and Ozark plateau, and is documented from 14 counties in Arkansas, Howell and Oregon counties in Missouri, and Adair and McCurtain counties in Oklahoma. While some populations have been sampled repeatedly over the past 75 years, (ex. type population in Stone Co., Arkansas), others are documented by single collections. Based on herbarium material, 50% of the known populations of *V. ozarkense* have not been sampled for more than 30 years, and some populations not sampled for as long as 80 years. Some Arkansas populations have conservation protection in the Ozark National Forest, and along the Buffalo National River.

Viburnum ozarkense populations in Missouri are afforded some protection at sites along the Eleven Point River in the Mark Twain National Forest. A population examined in 2000, at the western edge of the range in Adair County, Oklahoma, was composed of about 15 individuals and is not known to have conservation protection. The size and conservation status of the McCurtain County, Oklahoma population is unknown; this population has not been sampled since 1966. With a known distribution of 18 counties in three states, *V. ozarkense* clearly falls under the 26 county upper limit for rare southeastern endemics established by Estill and Cruzan (2001). *Viburnum ozarkense* should be considered for state listing in states where it occurs and attempts should be made to locate additional populations.

The commonness or rarity of *V. molle* throughout its range has not been critically reviewed. In Arkansas, *V. molle* is restricted to Madison and Boone counties (Fig. 3). The Madison County population of *V. molle*, was discovered by Shepherd in 1987 while working for the Arkansas Natural Heritage Commission. This population was re-visited in 2001 by Weckman and Shepherd and is estimated to consist of 35–50 individuals. It is on private land with no current conservation protection. An attempt by the author to relocate the Boone County population collected by Palmer in 1914 was not successful in 2000. The terse label information, "rocky ledges, Harrison" gave few clues as to its location. This population may no longer be extant. This research indicates *V. molle* is the rarest *Viburnum* species in Arkansas.

Viburnum molle occurs in 16 counties in Missouri. A population observed in Oregon County in 2001 was estimated to consist of about 12 individuals. Labels typically lack information about numbers of plants in a population; thus sizes of other populations are unknown. In the three state study area, herbarium

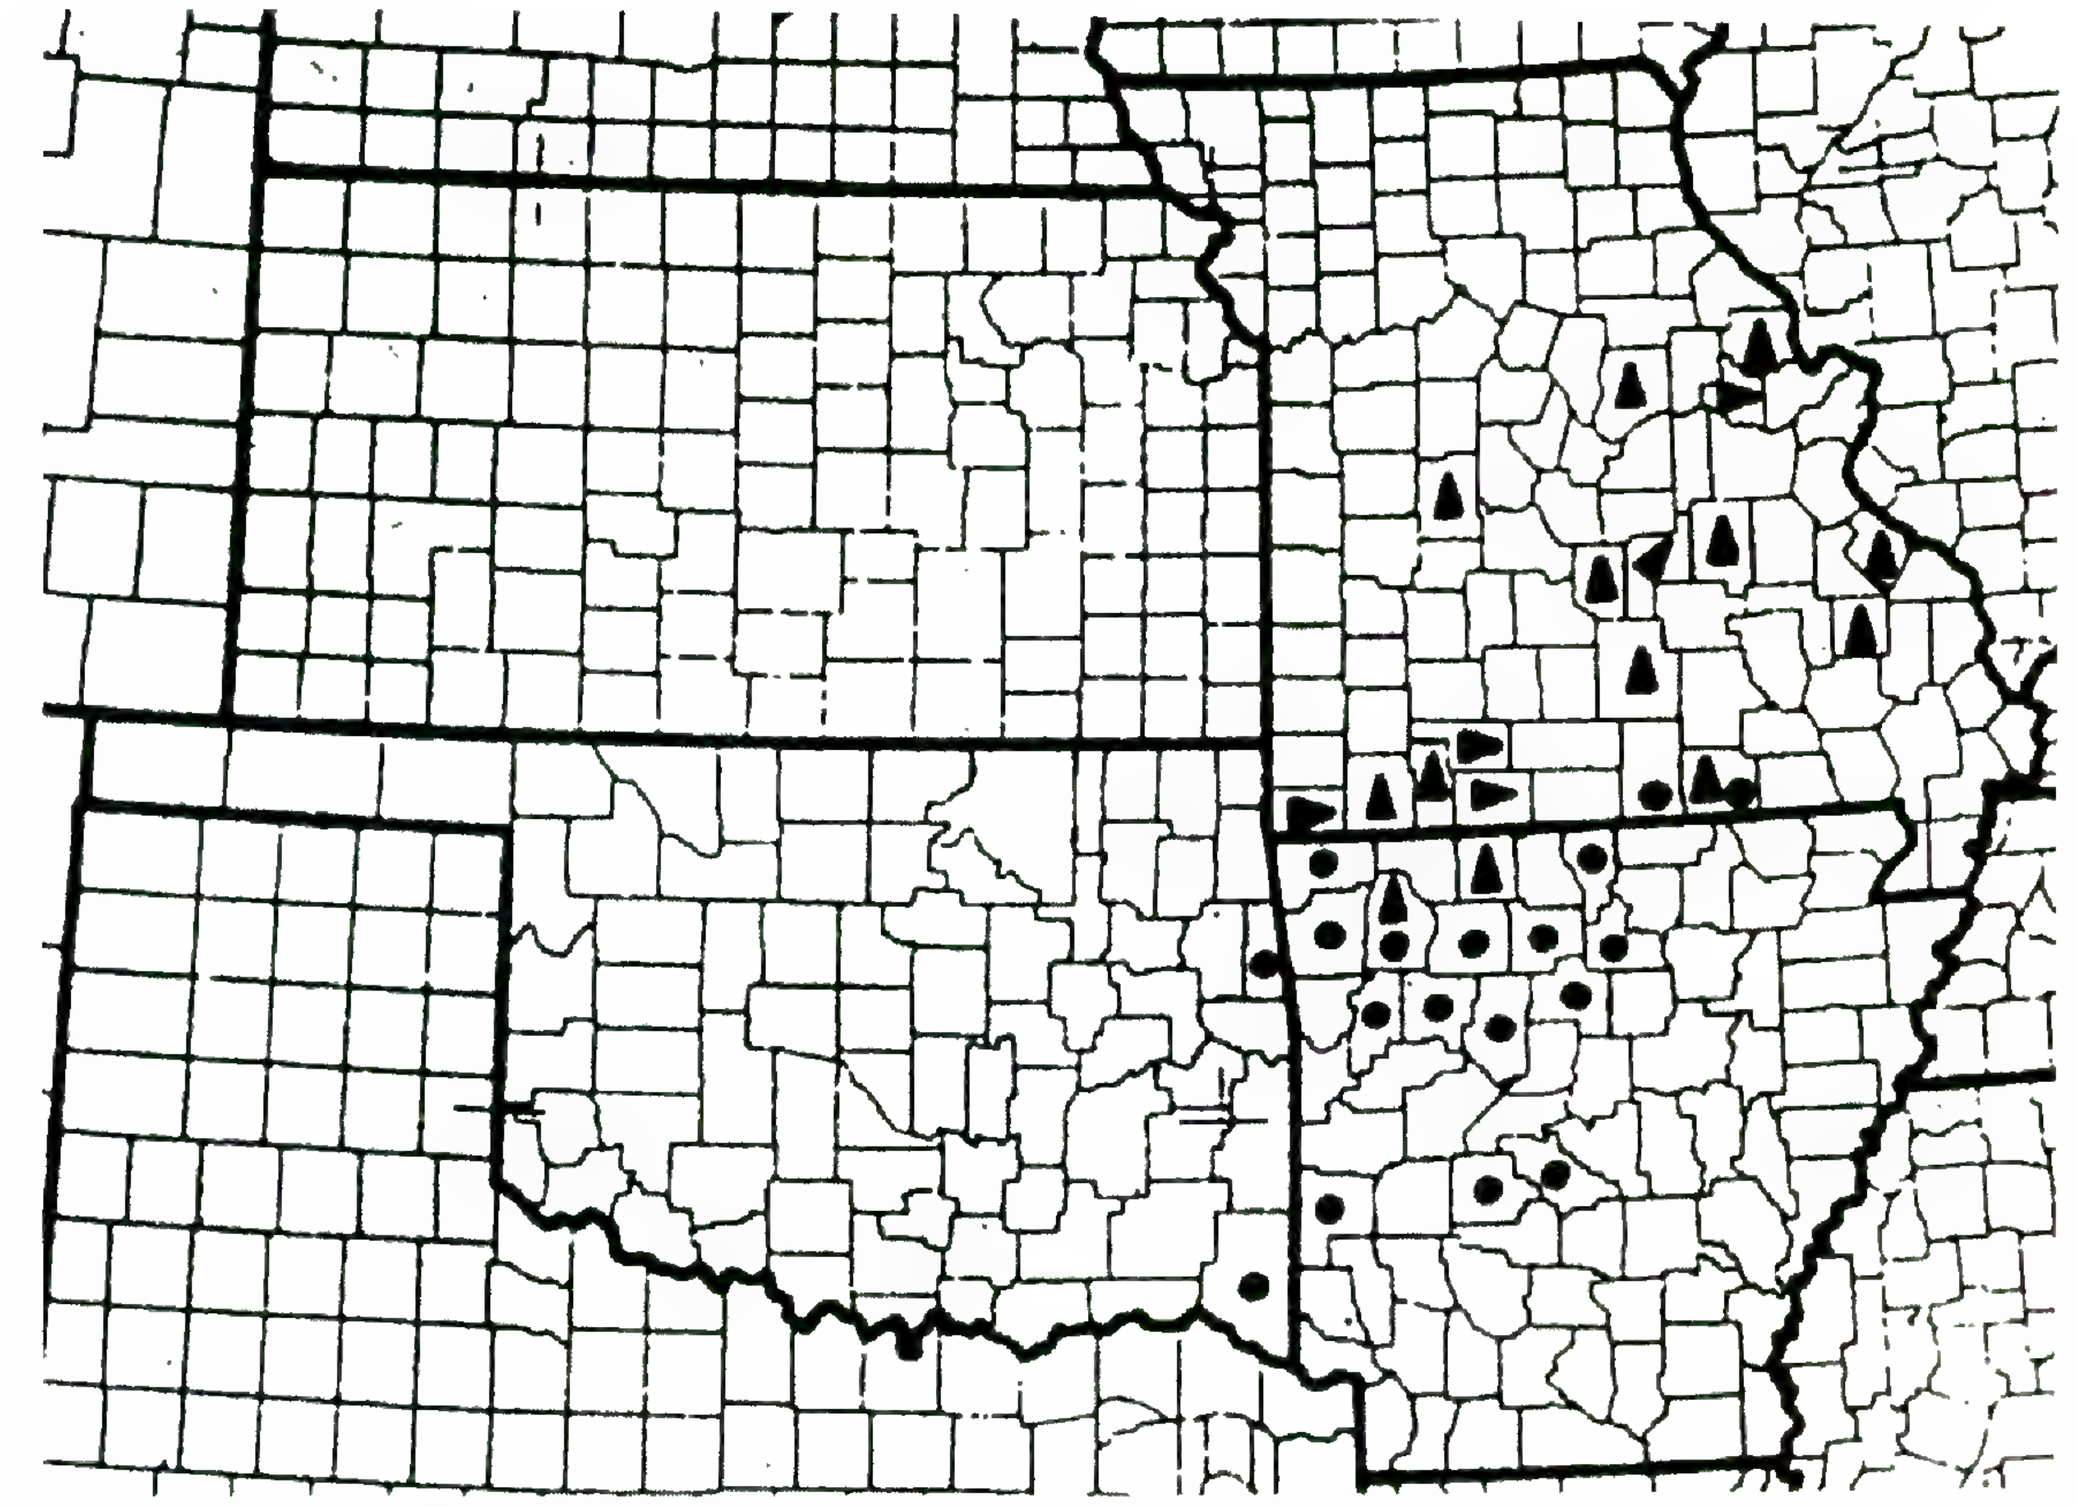

FIG. 3. Distribution of *Viburnum ozarkense* Ashe (●) and *Viburnum molle* Michx. (▲) in Arkansas, Missouri and Oklahoma, based on annotated herbarium vouchers.

vouchers examined of *V. molle* reveal that 50% of the counties were last collected in or before the 1950s. Conservation status of the Missouri populations of *V. molle* are unknown but some may be afforded protection in the various units of the Mark Twain National Forest and along the Eleven Point River.

Overlap of morphology and geographic range

For the mensural characters used in this study, ranges of the measurements overlap, however 8 of 14 characters were statistically significantly different at p= <0.05. If single character taxonomy is desired in the field, the *sine qua non* for *Viburnum molle* is the presence of exfoliating bark and conversely the absence of exfoliating bark defines *V. ozarkense*. This is an inviolate *Viburnum molle* character, used by Michaux in his type description, and observed by the author in the field for plants in Kentucky, Ohio, Missouri, and Arkansas, and on herbarium specimens of *V. molle* through its range in Tennessee, Indiana, Illinois, and Iowa. For determination of herbarium material collected without older stems, the suite of abundantly toothed leaf margins, short apex, and glabrous, terete petioles on yellow-tan twigs would lead one to *Viburnum molle*. Conversely, a specimen with moderately toothed leaves, longer, acute tips, and glandular-

pubescent, oval petioles on reddish-brown twigs would lead one to *Viburnum ozarkense*. These suites of characters allow for the differentiation of these two related species.

Viburnum ozarkense and *V. molle* co-occur in Madison County, Arkansas and Oregon County, Missouri, at the southwest edge of the range of *V. molle* (Fig. 3). In Arkansas the populations are about 30 air miles apart, while in Missouri the populations are about 12 river miles apart. No sympatric populations of *Viburnum molle* and *V. ozarkense* were located by the author, nor were any individuals appearing intermediate between these species observed in the field or voucher material examined.

ACKNOWLEDGMENTS

I would like to thank Stephen Walker who introduced me to the unusual "*V. molle*" of Arkansas and Bill Shepherd for facilitating re-location the *V. molle* population he discovered in Arkansas in 1987. Additionally, Johnnie Gentry, Burnetta Hinterthuer, Philip Hyatt, Lang Kirshberger, Gene Leeds, Janet Self, Karen Tinkle and Gary Tucker shared valuable locality information and provided logistical support in Arkansas. In Missouri, essential locality information was provided by Bill Summers and George Yatskievych. Analysis of statistical data was greatly facilitated by Judith Weckman. This work was supported in part by funding from the Office of the Dean, College of Arts and Sciences, Eastern Kentucky University. Finally, I am indebted to the curators of the herbaria listed above who generously lent from the specimens in their care.

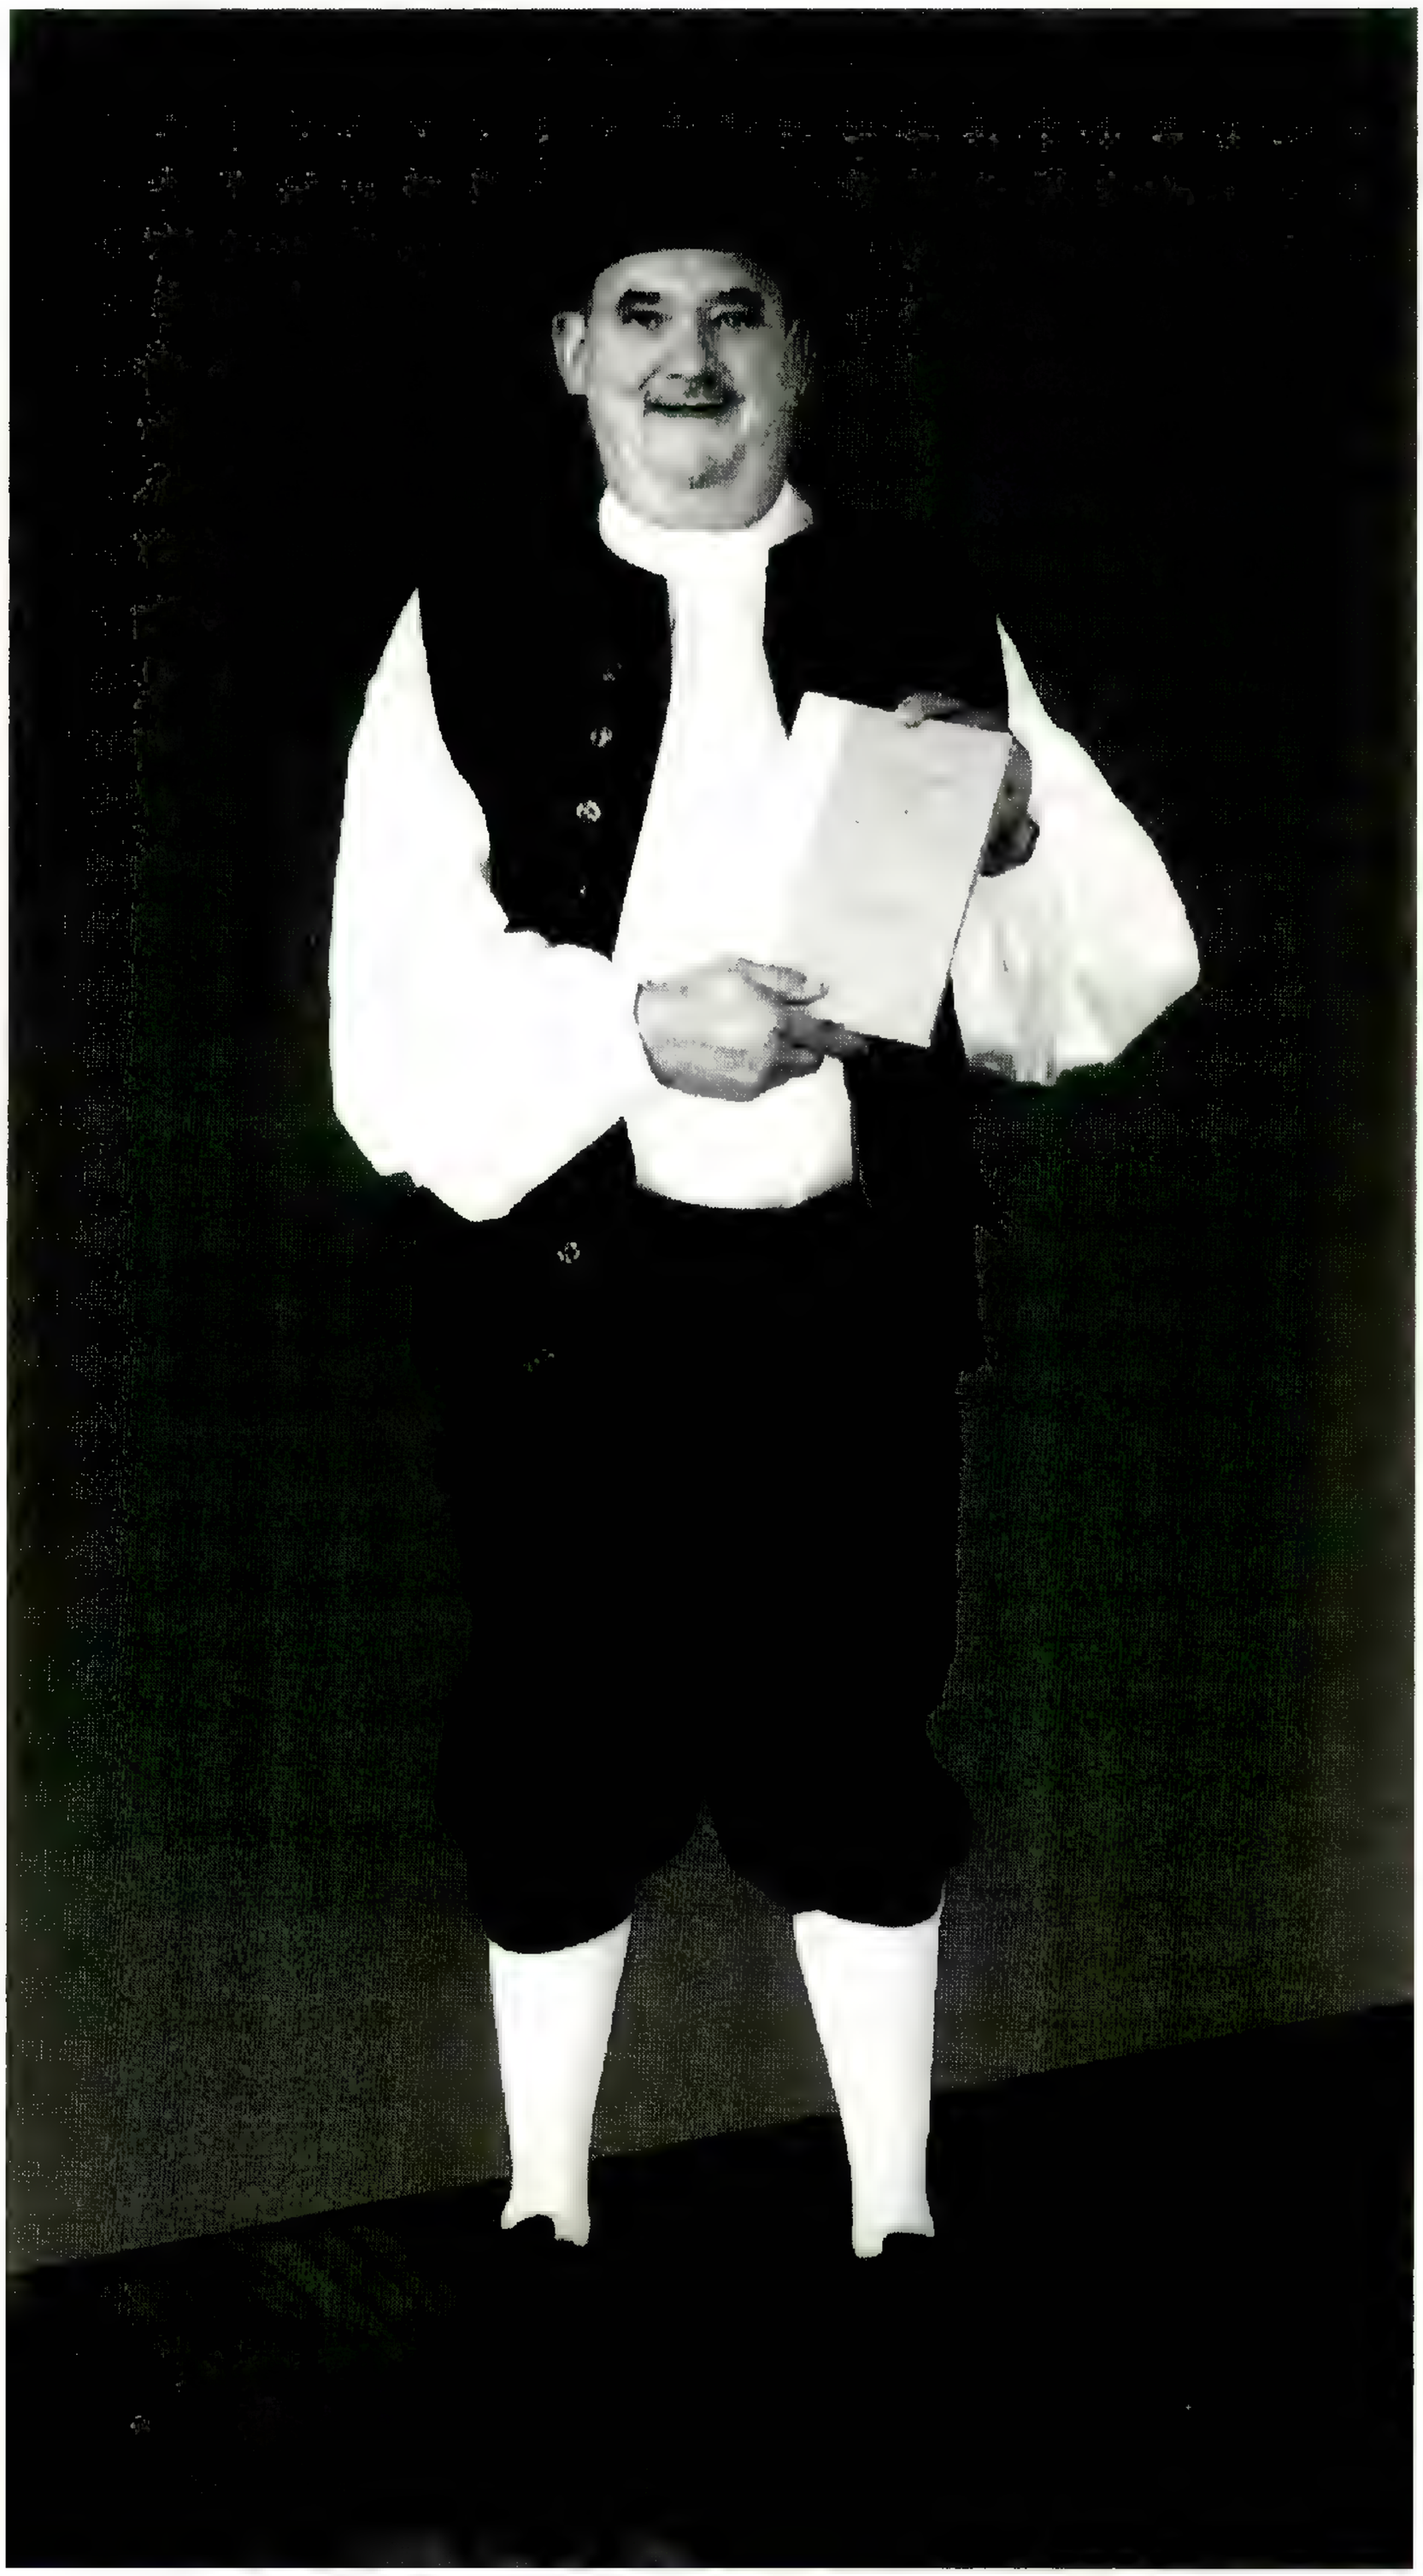
CELEBRATION HONORS PIONEER FIELD BOTANIST ANDRÉ MICHAUX

William R. Burk



John N. Couch Biology Library
University of North Carolina
CB#3280 Coker Hall
Chapel Hill, NC 27599-3280, U.S.A.

André Michaux, noted 18th century North American plant explorer extraordinaire, died on the island of Madagascar two hundred years ago. On the occasion of the bicentennial of his death, Michaux's life and contributions to North American botany were highlighted and elucidated at "A Michaux Celebration," attracting nearly 4,000 people. The events began with the André Michaux International Symposium (AMIS), held May 15-17, 2002 in Gaston County, North Carolina. The subsequent two days—called "Celebrate France! Festival Foire!"—occurred at the Daniel Stowe Botanical Garden, a relatively young garden with strong public programs. AMIS constituted the official symposium for the Southern Appalachian Botanical Society (SABS), held for the first time separately from the Association of Southeastern Biologists' annual meeting. Belmont Abbey College (BAC), the Daniel Stowe Botanical Garden (DSBG), and Gaston Day School (GDS) were the hosts of the celebration, three years in the planning. Librarian Charlie Williams was the key architect and organizer of the Celebration, whereas Jeanne Miller was the coordinator. Michael J. Baranski (SABS) served as Program Chair for AMIS. Others were Carol Brooks, Dean de la Motte & Robert Tompkins (BAC); Mike Bush (DSBG); Martha Mayberry (Mint Museum of Charlotte); Richard Rankin (GDS); and Jean-Pierre Riviere (French-American Chamber of Commerce, NC).

Setting the tone for the first day were two field trips, enticing and piquing attendees' curiosities and expectations of Michauxiana to come. That evening ethnobotanist Mark Plotkin delivered the opening address at the Gaston Day School. We learned about the importance of natural products from tropical Brazil and Surinam, such as a potential painkiller from the poison dart frog. He emphasized the need for a holistic approach to conserving tropical flora and fauna. Just as pioneer Michaux persevered under the rigors of exploration, conservation efforts require persistent leadership under equally challenging circumstances.

The fast-paced sequence of 28 fact-packed presentations of May 16 and 17, enlightened our knowledge of Michaux. James L. Reveal, historian of botany, delivered the plenary talk, "No Man is an Island: The Lives and Times of André Michaux." After placing into perspective the accomplishments of naturalists prior to Michaux's arrival in the United States, he discussed Michaux's contri-

SIDA 20(2): 861–864. 2002

Walter K. Taylor as André Michaux at AMIS, 16 May 2002, Belmont Abbey College, Belmont, North Carolina. (Photograph by Ronald L. Stuckey, Columbus, Ohio)

butions to field botany. Subsequent paper presentations were of two types: invited (9) and contributed (19). Two other scheduled papers on "The Lowcountry Connection of André Michaux" and "Nature and History of the Botanical Materials of André Michaux in the Herbarium of the Academy of Natural Sciences of Philadelphia" were not presented.

Each presentation was virtually unique in topic, overlapping little with others. Among the varied themes on Michaux and his activities, were: his connection with the Bartrams of Philadelphia; his Canadian journey; several accounts on plants—named as new to science by him—including *Magnolia macrophylla*; the rediscovery of the site of his botanical garden in Charleston, South Carolina by archaeologists from the College of Charleston; his involvement with the intriguing Edmund Charles Genet Affair in American history; and his excursion to Madagascar where he died on October 11, 1802 (confirmed by a newly discovered death certificate from Mauritius). When speaker/author Walter K. Taylor gave his talk on Michaux in Spanish East Florida during 1788, he appeared in a period costume, eliciting surprise and delight from the audience. In closing the symposium, Françoise Winieska, noted photographer of gardens and plants representing France at the program, gave a slide presentation, "18th century French Gardens in the Domains of Versailles and Rambouillet," sharing her striking photographs with the captivated viewers.

Additional field trips were held during the symposium and at its conclusion. We enjoyed two dinners at the Stowe Botanical Garden, the evening of May 16 being a "French Gala" of cuisine, eighteenth century period music and dance. On the last evening of AMIS a special treat was an exhibit of engravings and watercolors by eighteenth century botanical artist Pierre-Joseph Redouté at the Mint Museum in Charlotte. Opening in March 2002, the exhibit was specially developed as an adjunct to the Michaux symposium and included five associated talks, among them, "Botanical Illustration: Redouté and the Michaux," by librarian/historian Ian McPhail. The exhibit will close this year on Bastille Day, July 14.

During breaks and other free periods of time, attendees were lured by exhibits, such as the book displays by the Missouri Botanical Garden and by symposium speakers and other participants. Among the latter were books and audio-cassettes by C. Ritchie Bell; Gail Fishman; Walter K. Taylor and Eliane M. Norman; and Charlie Williams. Locally produced and limited in distribution, the booklet "Memoirs of the Life and Botanical Travels of André Michaux," by J.P.F. Deleuze is of special note to librarians and historians. Conceived and edited by Charlie and commemoratively published for the symposium, it contains four appendices, among them a supplementary bibliography by Ronald Gilmour. Charlie's role as editor is a misnomer of the extent of his contribution, as he is also the writer of two of the appendices. The Catawba Lands Conservancy prepared the useful color map folded in the back of the text. The map traces nine journeys that Michaux made in North America from 1787 to 1796.

The publication is available only from Charlie Williams, 6720 Wheeler Drive, Charlotte, NC 28211. Checks are to be written for $16.50 (which includes postage/handling) to "Belmont Abbey College." Artist and school administrator Erin Whitener had a popular display of her line of note cards, featuring color illustrations of plants discovered by Michaux, which sold out early in the program. Her design of the *Magnolia macrophylla*, leaf or fruit, appeared on symposium stationery, handouts, and tote bags given to attendees

Two AMIS booklets in our orientation bags may be of interest to others, particularly librarians. These were an "Attendee Roster" containing names, titles, addresses, phone, fax, and email addresses of all attendees; and "Abstracts," providing succinct summaries of each presentation. Fortunately, the proceedings of AMIS are planned to be published in *Castanea* and its *Occasional papers*.

The French Festival featured special talks, French cuisine, and vendors of merchandise such as artwork, jewelry, and Limoge porcelain. This Festival was open to the public and included activities for children such as face painting, games, and guignol (a Punch and Judy show). Sponsored by the French-American Chamber of Commerce (NC), this event took place at the Stowe Garden on May 18 and 19.

The Michaux Symposium is a model for future theme-type conferences. Both the Symposium and the highly popular "Celebrate France!" were resounding successes. The fervor of symposium goers was evident as noted by conversations sparked by the presentations and scholarly interests of those in attendance. Special thanks are extended to the organizers, hosts, and myriad behind-the-scenes people for bringing together such a distinguished assemblage of Michaux scholars and providing a wide array of events.

Historians of botany will have access to a collection of information sheets and brochures available at the conference that have been assembled by The Ohio State University botanist Ronald L. Stuckey. He has deposited the compilation in the Hunt Institute for Botanical Documentation, Pittsburgh. This contribution also includes all of the photographs he took of the invited speakers participating in AMIS.

The symposium will be a lasting contribution to the history of botany, bringing visibility and recognition to the great botanical pioneer André Michaux. "Celebrate France!" accentuated the important French contribution to American culture. "Celebrate Michaux" merged science and culture to make for a fascinating five days of learning and entertainment. Vive Michaux! The influence of Michaux also was recently recognized by the NC Department of Highways, which landscaped an intersection of Interstate 85 in Gastonia with plants first discovered by Michaux. The plot is identified with a permanent marker.

ACKNOWLEDGMENTS

Ronald L. Stuckey, The Ohio State University, Columbus, assisted with writing the paper (May 24, 2002).

DEL WENIGER (1923-1999), REMARKABLE TEACHER AND NATURALIST

Marjorie Fohn Epler

924 East 50th Street
Austin, TX 78751, U.S.A.

In 1960, Del Weniger joined the faculty of Our Lady of the Lake College in San Antonio, Texas.

He was later to become the chairman of the Biology Department. After teaching general biology and ecology for nearly forty years, Del retired from O.L.L. in 1988 as Professor Emeritus.

Although born in Kingman, Kansas, Del thought of himself as an adopted Texan. Appropriately so, since he researched the plants and animals of the state for half a century, this resulting in numerous published articles, and his first two books, Cacti of the Southwest and Cacti of Texas and Adjacent States. The first book received, in 1970, Theta Sigma Phi's "Author of the Year's Best Book By A Texas Publisher" award, as well as accolades from numerous organizations and reviewers. *Echinocereus wenigeri*, a Texas cactus was named for him.

His first two books were followed by Explorers Texas, Vol. I, which the Texas Historical Commission judged to be the "Best Historical Publication of 1984." Vol. II of the series soon followed. Volumes III and IV were in progress at the time of Del's death. He also co-authored the book, San Antonio in the Eighteenth Century, which received the Texas Historical Commission's 1978 "Official Texas Award For The Best Publication of the Year in Local or Regional History."

Del spent many hours researching whatever was written down by the early explorers and pioneers of Texas. His family and friends remember the great pleasure he took in finding new journals or letters of early explorers or settlers who recorded what they saw as they traveled Texas. His deep sense of stewardship of the earth and its gifts was evident in his teaching, his lectures, his volunteer work, and his ecological consultation for federal and local agencies. He stressed responsible, respectful use of our natural heritage as he served as a founding member of the San Antonio Botanical Center, and on local, state and regional boards of the Nature Conservancy and Sierra Club.

A thorough-going naturalist with a respect for all forms of life, Del exhibited an educator's affection for those of his students who demonstrated enthusiasm for the study of biology. As a former student I can attest to his effectiveness in teaching both the fundamentals of ecology and the delight of field work associated with such studies. Professor Weniger loved teaching as much as he loved learning and always took extra time for a student's interest or inquiry.

SIDA 20(2): 865–866. 2002

Those of us who were familiar with Del Weniger's dedicated working habits and regular good humor were amazed to learn, upon his death, that he had been living, since birth, with an illness called Eisenmenger Complex, a condition whereby a person is born with only a 3-chambered heart. Medical experts think that, because of the heart having to work so much harder, one's life expectancy is lowered to less than 40 years. Delbert Kenneth Weniger, born May 10, 1923, died at the age of 76 on July 10, 1999.

Del Weniger (1923-1999)

Book Reviews

The National Biodiversity Team of the Republic of the Marshall Islands. 2000. **The Marshall Islands, Living Atolls Amidst the Living Seas: The National Biodiversity Report of the Republic of the Marshall Islands.** (ISBN 982-9045-02-1, pbk.) St. Hildegard Publishing Company. Santa Clarita, CA 85719, U.S.A. Price not given, 345 pp, numerous illustrations, 8 1/2" × 11".

During the Earth Summit in Rio de Janeiro, Brazil in 1992, the Republic of the Marshall Islands was among the first to sign the Convention on Biodiversity. Consequently, the Republic sanctioned a report on the biota of its atolls with the hope of raising public awareness to the various aspects of biodiversity. The goal of this report is to "provide background about the Marshall Islands, its history, especially in relation to plants, animals and ecosystems, to give an overview of its biodiversity and biological resources" (p.3). It is mainly a compilation of biological information previously published by other scientists, place in a single format, thereby making it more accessible to the residents of the Marshall Islands. Even the writing style is informal, "with the idea of making the information available to all sorts of people, even high school students."

While on the surface this book might seem appropriate for only a small target audience, only a brief look into this book reveals many informative features. Many of the organisms are illustrated, such as the reef crab and giant grouper, with the Marshallese name and derivation provided. Text boxes featuring a special topic present important biological concepts. A section on "What is a Coral" informs the reader about the different groups of corals and coral-like organisms. Likewise, a section on endemism defines the topic and the term "invasive species" is discussed in some detail.

The first part of the book is comprised of three chapters, which deal with the history of the Marshall Islands and its people, biological resources, and threats to biodiversity. Chapter one begins with a short historical account of the Marshall Islands and its people, history about the formation of the Marshall Island atolls and their relatively recent colonization by terrestrial life only 3,000-4,000 years ago. Furthermore, the detrimental effects people have had on the atolls, with the introduced plants and animals they brought, has resulted in the extinction of several species, including the endemic flightless Wake rail, the purple-capped fruit dove and the Micronesian pigeon. The history of government reveals that the Marshalls have been under the control of several countries, including Germany, Japan and the United States, before becoming their own commonwealth in 1990 and joining the United Nations. This chapter also provides information on the individual atolls comprising the Marshalls, with the Marshallese names of each, the number of square land miles they occupy, and brief historical information.

Chapter two, entitled "Biodiversity and Biological Resources," gives a brief overview of the ecosystems on the Marshall Islands, listing each by plant community and including information on location, importance, status and threats. Following is a concise overview of the biota of the Islands, divided into plants and animals, with tables to give quick information about total number of species, percent native species, percent endemism, number of threatened and endangered species, etc. The fragility of these islands and invasive nature of newly arrived exotics is evident in these tables, since only 18% of vascular plants and 23% of animals are native.

Chapter three deals with current and historical threats to biodiversity, which include nuclear testing, the invasion of exotics, changes in population and lifestyle of the native people and global climate change.

The second half of the book is dedicated to tables and lists of biota. Separate tables are included for plants, pulmonate and non-marine mullosks, spiders, insects, fish, reptiles and amphibians, birds, and mammals. For each of the species in these tables, scientific name, English name, Marshallese

name, status and traditional uses are reported. Next, information on biota deemed worthy of conservation concerns with definitions of conservation terminology (example: threatened vs. endangered). In addition, a table of endemic species, one on pestiferous and invasive species and those species protected by Marshall Island law ease the reader in identifying biota of critical importance. Illustrations are found throughout the book, often with scientific and Marshallese name, and five color figures with keys to identify the organisms in an important community, such as a coral reef. These illustrations enhance the book's properties, helping reader appreciate the biodiversity on the Marshall Islands.—*Amy Trauth Nare, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX, 76102 U.S.A., amy_trauth@yahoo.com.*

CHARLES H. SMITH. 2000. **Biodiversity Studies: A Bibliographic Review**. (ISBN 0-8108-3754-4, hbk.) Scarecrow Press, 4720 Boston Way, Lanham, MD 20706. U.S.A. http://www.scarecrowpress.com (Orders: The Rowman & Littlefield Publishing Group, 15200 NBN Way, Blue Ridge Summit, PA 17214-0191, U.S.A., 800-462-6420). $69.00, 449 pp, 5 1/2" × 8 1/2".

Charles H. Smith, Science Librarian and Associate Professor of Library Public Services at Western Kentucky University, cites literature both on the biological study of diversity itself, and on the socio-natural science of diversity conservation. His effort has received two very prestigious recognitions. His work was listed in *Library Journal*'s Best Reference Sources for 2000, and it won the biannual 2001 Oberly Award for Bibliography in the Agricultural or Natural Sciences.

Two bibliographies are included in this work. Bibliography I, "Books and Articles," lists approximately 1,200 monographs and 4,500 articles, while Bibliography II, "Special Issues," provides a selective accounting of special issues of journals/serials dealing exclusively with biodiversity in all aspects. His emphasis is on the literature of the investigation of biodiversity, the written record of efforts to measure, understand, monitor, and preserve it. Some self-imposed restrictions had to be considered during his exhaustive literature search, which included over one hundred electronic databases and an equal number of print bibliographies and references cited lists. Because of space limitations individual papers appearing in edited collections were excluded, as were electronic sources, theses, dissertations, reference works, systematic or floral/faunal revisions, and juvenile literature. Almost every entry in the list is in the English language. What is featured is the primary literature of biodiversity-directed natural science, social science, and humanities subjects, with a select amount of science journalism. Coverage centers on the period 1986 to 1998, but extends to many works published prior to that date that remain relevant to trends occurring during it.

His basic goal was to provide as much information as possible in as little space as possible for each entry. Each citation is enhanced with bibliometric ratings, brief annotations, and/or a list of descriptive "added terms." The bibliometric rating for journals appears as a 1 to 3 scale according to the average number of times they have been listed as cited over a several- to ten- or twelve-year period in the combined *Citation Index* portions of *Science Citation Index, Social Sciences Citation Index,* and *Humanities Citation Index*. Monographs are rated on the same 1–3 scale but on three different factors: (1) the number of OCLC libraries who hold the item; (2) number of times the work was reviewed after publication, and (3) number of citations it has generated. Both ratings appear in brackets after the pagination in the citation. An "Honors" list appears in his introduction for the ten most frequently mentioned publishers and the twelve serial publications most frequently cited. The addition of the bibliometric ratings makes this bibliography not only unique but also especially useful due to its analysis of the relative importance or value of each entry.

The three indexes, covering general, geographical, and organismal subjects, respectively, generate over 20,000 referrals to the items in the bibliography. Index I is alphabetically arranged by subject. Index II is divided into nine regional lists. Index III contains nine taxonomic lists. The indexing features many cross referrals because so many of the significant concepts in the developing field

of biodiversity are associational. The other major feature of the indexes derives from the bibliometric approach taken in Bibliography I. Item numbers in the Indexes that are underlined represent works which were rated with the higher scores. This feature will make it easier to prioritize readings. The work also surveys closely related topics from such allied fields as environmental ethics, nature philosophy, environmental law, agricultural ecology, evolutionary biology, biometrics, sustainable development, environmental policy, forestry, genetics, education, climatology, and paleobiology. It provides a good overview of important research and will make the literature review process easier.

While "Biodiversity Studies: A Bibliographic Review," is highly recommended for scientists, educators and professionals-to-be, it cites a fair amount of material that can be understood by undergraduates or even high school students. This book would be a valuable addition to library reference collections and should be in all graduate and professional library collections.—*Gary L. Jennings, Botanical Research Institute of Texas, Fort Worth, TX 76102-4060, U.S.A.*

MARY TOOMEY and EVERETT LEEDS. 2002. **An Illustrated Encyclopedia of Clematis.** (ISBN 0-88192-508-X, hbk.). Timber Press, Inc., 133 S.W. Second Avenue, Suite 450, Portland, OR 97204-3527, U.S.A. (Orders: www.timberpress.com, 800-327-5680, 503-227-2878, 503-227-3070 fax). $59.95, 428 pp, 652 color photos, 5 b/w illustrations, 151 line illustrations, 2 maps, 8 1/2" × 11".

An Illustrated Encyclopedia of Clematis was written by distinguished Clematis experts Mary Toomey and Everett Leeds and supported in spirit and publication by the British Clematis Society. Their goal was to produce a reliable, substantial and definitive work on the genus. This comprehensively illustrated work will meet those needs, particularly of passionate gardeners, hybridizers, and nurseries.

The popularity of the genus *Clematis* as a garden plant rose dramatically in the 1990s in part because of the extraordinary diversity of its flowers and in part because gardeners were exposed to a better and wider range of large flowered cultivars from all corners of the world. Clematis, be they cultivars or species, can also be found in bloom almost every month of the year. Add the astonishing range of flower color and the size and shape of the flowers and it becomes apparent why clematis has been justifiably crowned queen of the climbers. They are very accommodating garden plants. Drama, rhythm, and movement can be created in a garden of any size or shape. Widely known as climbers, the genus also includes shrubby, and herbaceous species and cultivars.

It is the first-ever encyclopedia on the genus and includes more than 550 garden-worthy species and hybrids of the more that 800 listed in the *Royal Horticultural Society's Plant Finder* (1999-2000 ed.). Profusely illustrated, there is an full-color illustration for each of the species and cultivars described located next to the detailed description.

This long-awaited book is separated into two Parts. The first Part is devoted to the care and cultivation of clematis, history and botany, pruning, propagation and hybridization, pests and diseases, and a chapter devoted to growing clematis in North America. The second Part provides an A–Z directory of more than 550 plants, from the acclaimed large-flowered forms to the less familiar shrubby, sub shrubby, and herbaceous forms that are beginning to be available. Using everyday language, the authors provide plant descriptions that include information on synonyms, origin, plant habit and height, flowers, pruning group, flowering period, cultural requirements, recommended uses in the garden, and hardiness zones. Several useful appendices assist gardeners in choosing the right plant for the right site and in obtaining reliable plants and seeds. A list of nurseries is included which specialize in mail order, both foreign and domestic. There is also information included to enable gardeners to choose a clematis by name or by color. The text is accompanied by more than 650

magnificent color photos, making this encyclopedia an indispensable reference and guide. This book is written by gardeners with a passion for these wonderful, colorful plants for gardeners with a passion to grow them. It is recommended for all gardeners and amateur growers, as well as the nursery professional and those libraries serving them.—*Gary L. Jennings, Botanical Research Institute of Texas, Fort Worth, TX 76102-4060, U.S.A.*

MAGNUS JOHNSON. 2001. **The Genus Clematis. Edited and Translated by Bengt Sundström.** (ISBN 91-631-1030-X, hbk.). Magnus Johnson Plantskola AB and Bengt Sundström, Bränningestrandsvägen 63, 151 39 SÖDERTÄLJE, Sweden. (Orders: 08-550 979 77; +468 550 970 77). $110.00, 896 pp, 24 gouaches, about 100 illustrations from classical literature and ink drawings by the author, about 170 color photos, 6 3/4" × 9 1/2".

The Genus Clematis, by Magnus Johnson, is a summary of the knowledge the author acquired during his career as a botanist, landscape architect and nurseryman about clematis. He purpose was to provide a historical review of its use and cultivation in gardens and to present an ordered arrangement of descriptions of the species and cultivars.

There are plants esteemed for their fragrance roses, lilies of the valley, others because they are associated with certain values—bluebonnets of spring, saw tooth maples bursting into color, tall grass prairies reaching to the sun, and still others charged with symbolism—white lilies, red poinsettias and blue forget-me-nots. A clematis has its effect by its immediate beauty. The shape of the flowers, the infinite variation of color, their graceful and elegant foliage. One may experience this through the beauty and structure exhibited in the gouaches and ink drawings of Magnus Johnson's reproduced in this work. He was awarded the Grenfell Medal by the Royal Horticultural Society for his gouaches.

The book is presented in three parts. The first deals with the history, horticultural aspects, and the cultivation and propagation of clematis. The second part is a scientific description of clematis and gives an overview of different characteristics in text and drawings. It also includes a historical review of the genus classification by different scientists cumulating with the author's view. In the third part, each section is introduced by a description of general characteristics, maps showing the distribution of each section, and comments on the use of Clematis in gardening. Each description begins with references to the literature cited, with a complete bibliography following the description section. A total of 325 species are described with around 180 varieties and 1,400 cultivars treated. A basic terminology of particular words used in the text is included, with about 200 words, in English-German-French-Latin and -Swedish listed.

Originally published in 1996 in Sweden, this translation undertaken by Johnson's son-in-law. He has delivered with flair both the charm and intrinsic beauty of the work. Dr. Mary Toomey assisted in turning the translation into readable English and in developing the chapter on history, taxonomy and characteristics.

This book is recommended for serious gardeners, nursery professionals, and botanists and researchers who wish to understand clematis better. Highly recommended for libraries serving this population. It is too early to declare that this is a classic but it bears all the markings of one.—*Gary L. Jennings, Botanical Research Institute of Texas, Fort Worth, TX 76102-4060, U.S.A.*

JAMES F. FRALISH and SCOTT B. FRANKLIN. 2002. **Taxonomy and Ecology of Woody Plants of North American Forests (excluding Mexico and Subtropical Florida).** Illustrations by Hyosun Park. (ISBN 0-471-16158-6, hbk.) John Wiley and Sons Inc. One Wiley Drive, Somerset, NJ 08875, U.S.A. (Orders: 732-469-4400, 732-302-2300 fax). $100.00, 624 pp, 550 line drawings.

Advances and developments in forestry and wildlife management in recent years have been borne out of vast amounts of scientific information and heightened public awareness of the value of our forests. This book seeks to educate its audience about the taxonomy and community ecology of North American forests. It begins with two chapters that appropriately introduce reader to taxonomy and forest ecology. Key ecological terms, such as population vs. community, are clearly defined, a section on forest community ecology and community (cover) types is included, and taxonomic concepts are introduced. Taxonomy seems to be one of the major themes in this book, with more emphasis on the principles of taxonomy and less on simple sight identification of only important commercial trees.

The book is generally divided into four major parts: **I.** Taxonomic Concepts and Methodology, **II.** Gymnosperms (Division Pinophyta), **III.** Woody Angiosperms (Division Magnoliophyta), and **IV.** Forest Community Ecology: Combining Species into Communities. **Part I** begins with the fundamentals of plant classification. Definitions of family, genera, species are provided, as well as explanations of latin binomials and author names. Proper techniques for collecting, labeling and preserving plant specimens are explained. Finally, the authors instruct on how to construct and use taxonomic keys.

In **Part II,** gymnosperms are considered. The section begins with an overview of gymnosperms, which includes, for example, sections on evolutionary history, wood composition and geographic range. The following chapter is a discussion of vegetative and reproductive structures. Subsequent four chapters are comprised of taxonomic descriptions of gymnosperm species in the Pinales, Taxales, Ginkgoales and Cycadales.

Part III deals with woody angiosperms, beginning like part II with an overview of the group. Information is included on life form, morphology and the taxonomic classification that follows Cronquist. There are two chapters on vegetative morphology and one chapter on reproductive morphology. The following eight chapters are dedicated to taxonomic descriptions. As in part II, taxonomic descriptions begin with a short discussion of familial characteristics, the number of taxa and taxonomic affinities. After each family are individual species descriptions with common names, a comprehensive, yet not overly complex discussion of morphological characters, economic importance, geographic distribution and cover types. Cover types can be cross referenced to part IV.

Last, **Part IV** interprets forest community ecology, integrating the gymnosperm and angiosperm species previously discussed into communities. The first chapter in this section explains the different factors that contribute to forest composition. Factors such as climate, soil, topography and geology are considered. Moreover, a discussion of forest classification systems is put forth. To identify communities within natural vegetation regions, the authors employed the National Vegetation Classification Standard developed by the Nature Conservancy and developed their own naming strategy for the various communities described, which closely follows the Society of American Foresters' cover type system. The last five chapters of this book describe different forests in North America. Generally, these include Northern Conifer-Hardwood, Central Hardwood, Southern Pine-Hardwood, Rocky Mountain Conifer, and Northern and Southern Conifer Forests. The book ends with glossaries of technical terms and genus and species names, and separate species and subject indices.

This review would be incomplete without some recognition of the illustrations provided in this book. With 550 line drawings, the majority of the species described herein are illustrated. These

illustrations are informative, expository and beautiful. While they enhance the aesthetics of the book, they also tremendously increase the scientific value by providing a clear identification tool to support each species description. With more than 800 species described, this book is absolutely packed with information on woody plants. The comprehensive nature of this book makes it invaluable and a necessary text for any classes where dendrology, taxonomy, forestry, botany, resource management or environmental studies are taught. Fralish and Franklin have clearly set a high standard for the future of dendrology texts.—*Amy Trauth Nare, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX 76102, U.S.A., amy_trauth@yahoo.com.*

DONALD WATTS. 2000. **Elsevier's Dictionary of Plant Names and their Origin.** (ISBN: 0444503560, hbk.). Elsevier Science B.V., Sara Burgerhartstraat 25, P.O. Box 211, 1000 AE Amsterdam, The Netherlands. $209.50, 1001 pp, 6 1/2" × 9 1/2".

The dictionary contains about 30,000 vernacular and literary names of plants (primarily of English origin, although American, Australian, New Zealand, and South African names are included), both wild and cultivated, with their botanical name and a brief account of the names' meaning if known

Knowledge of plant names can give insight into largely forgotten beliefs. Such names were probably the result of some taboo against picking the plant or eating the fruit. Names may also be purely descriptive, and can also serve to explain the meaning of the botanical name. Literary, or "book" names, have also been included in this dictionary, as being a very important part of the whole. That is, names of plants that were written but never used in the vernacular. Names in many instances provide links to the transmission of words through the ages.

The work represents an extensive accumulation of names from a wide diversity of sources. An entry is presented by the vernacular name followed by its botanical (Latin) synonym. This may be expanded by the addition of a vernacular synonym and the source of the primary epithet. Users must reference the source by referring to the bibliography at the front of the dictionary. There is access to a botanical name when a vernacular name is known but not the converse. There is no index of botanical names. There is not a single main entry for vernacular 'binomials'. Each part has its own complete, and largely duplicated, entry. There are no cross-references, thus Aaron's Beard and Beard, Aaron's share the information. All of the vernacular synonyms have their own individual entries rather than being grouped together under a common botanical name.

The work was conceived as part of the author's wider interest in plant and tree lore, and ethnobotanical studies. A labor of love, a monument to the author, but its bulk, poor editing, out-of-date botanical nomenclature, and price only serve to make this less than an adequate choice for most libraries or researchers. Its restricted geographic scope also weighs against a potential purchase. It is not only British in scope, but heavily biased towards southern Britain. Although many of the names listed are current, most belong in the past, and the author makes no attempt to indicate which are current. This work is recommended only for those very large libraries that must have everything available on the subject.—*Gary L. Jennings, Botanical Research Institute of Texas, Fort Worth, TX 76102-4060, U.S.A.*

DAVID J. SCHMIDLY. 2002. **Texas Natural History: A Century of Change.** (ISBN 0-89672-469-7, hbk.). Texas Tech University Press, P.O. Box 41037, Lubbock, TX 79409-1037, U.S.A. (Orders: 800-832-4042, www.ttup.ttu.edu/). $39.95, 576 pp, 144 b/w figures, 43 maps, notes, 7" × 11".

With the publication of "*Texas Natural history: A Century of Change,*" Dr. Schmidly has done a great service for both professional and amateur naturalists in Texas. The bulk of this volume is a re-publication of Vernon Bailey's "*Biological Survey of Texas.*" The survey was conducted between 1889 and 1905 by Bailey and twelve "federal agents" and was published in 1905. The *Survey* has been out of print since the 1920s, so it has been inaccessible to older naturalists and essentially unknown to younger naturalists. The *Survey* contains a wealth of information that is valuable for the historical perspective it provides as well as forming a basis of comparison with the current status of biological diversity in Texas.

The **first chapter** of this seven-chapter book covers the historical setting and events leading up to the initiation of the biological survey of Texas. Dr. Schmidly provides a detailed account of the people involved, their personalities, and their professional and personal lives. In fact, there is so much information that it may be bewildering for readers who have little knowledge of the important figures in the history of natural history. In spite of the voluminous information in this chapter, some details that would be of considerable interest are lacking. In addition to the people, Dr. Schmidly covers the political situation and the government agencies involved in the effort to document the nation's biological resources. One of the motivations of this effort was agricultural concerns, especially in the western states, so much of the survey was focused on plant communities and mammals, whose economic and agricultural impacts are potentially great. Thus Dr. Schmidly's approach is decidedly, admittedly, and appropriately centered on mammals.

The **second chapter** is the re-publication of the *Biological Survey of Texas*, which covers pages 51–266 of the book. The first 37 pages of the *Survey* describe "faunal areas" or "life zones" of Texas, and outlines their characteristic flora and fauna. This section of the *Survey* contains much valuable information for those interested in the vegetation zones of the state and their associated vertebrate fauna. The next several pages cover lizards and snakes, although amphibians are unfortunately completely omitted. The remainder of the *Survey* is a detailed account of the biology, distribution, and conservation status of 181 taxa of mammals. By any standard, this is an impressive contribution to scientific knowledge, and in this case the information was obtained under conditions that were primitive at best. Forty-nine new taxa of mammals were described through the efforts of the survey team, nine of which were first described in the *Survey* itself. As Dr. Schmidly points out, all but nine of these species are currently recognized as valid, which is testament to the scientific ability of the federal agents. Obviously the mammal section of the *Survey* contains much information of historical value, such as reports of large carnivores and ungulates, but it also contains information that elucidates changes in distribution and abundance of rodents, bats, "varmints," and other species of current biological interest.

In **chapter 3,** "Annotations of the *Biological Survey of Texas*" Dr. Schmidly updates the information presented in the *Survey*, and includes changes in taxonomy, nomenclature, distribution, and abundance, as well as comments on conservation status. The information comes from the scientific literature and the author's decades of experience with Texas mammals. This chapter will be of considerable use to professional mammalogists in comparing the information in the survey with current knowledge, and in interpreting changes in patterns of distribution and abundance. For the informed amateur or the professional field biologist who specializes in an area other than mammalogy, Chapter 3 gives a look at the give and take through which taxonomy and systematics proceeds, and

at changes in the fauna as well as changes in the scientific study of the fauna. We also occasionally get a glimpse into the past that highlights the professional activities of predecessors or old friends.

Chapter 4, "Texas Landscapes, 1889–1905" gives Bailey and the federal agents the opportunity to tell us what they saw in their own words, and through their photographs show us the Texas landscapes they saw. This chapter will fascinate anyone interested in biogeography and the biotic districts of Texas. The many photographs and first-hand descriptions reveal landscapes that were in many instances already heavily transformed by human activity. According to Dr. Schmidly, "Of all the community types...the greatest adverse impacts appear to have been on grasslands." In fact, the blackland prairies of north central Texas are barely mentioned in the survey. This should not be surprising because the blacklands are among the most fertile areas of the country, and had been converted to croplands long before the years of the biological survey. In reading the accounts and seeing the photographs, it appears that some Texas landscapes were more heavily transformed in the late 1800s than they are today. This realization gives hope that remnants of each of the "life zones" of Texas may be preserved. Unfortunately, other information in this chapter makes it clear that there is little hope that Texas biological communities can be restored to a state even vaguely similar to their condition before settlement by Europeans.

Chapter 5, "Twentieth Century Changes in Texas Landscapes and Land Uses" continues the development of the idea that although the 20th century was one of dramatic change in Texas biota, the reader should not assume that there had been no changes prior to the years of the survey. In fact, one of the most important points of this work is that much of the Texas landscape had been altered substantially before the survey was conducted. Another important point is that not all of the changes that have occurred since the survey were for the worse. Many changes in the 20th century have come about through conservation and restoration efforts by government agencies, private organizations, and concerned landowners.

Chapter 6 on "Twentieth Century Changes in the Texas Mammal Fauna" will probably prove to be the most useful to professional mammalogists. This chapter discusses several categories of changes that have occurred, including local (e.g. within Texas) extinctions, dramatic declines in abundance, changes in distributions, and discovery of new taxa.

Sections on the introduction of exotic ungulates for show and hunting (the "texotics") and on the historical development of mammalogy in Texas will interest the amateur naturalist. The section on "Introduction of nonindigenous species" appears to take Dr. Schmidly pretty far afield; why not just say "exotic" rather than "nonindigenous"? The discussions of the red imported fire ant and the brown tree snake barely scratch the surface of the literature on these exotic species and their effects on endemic biota

Finally, in **chapter 7,** Dr. Schmidly discusses "Challenges for Wildlife Conservation in Texas." This chapter is insightful in some places but frustratingly vague and incomplete in other places. In the first pages the discussion leaves unanswered or glosses over some potentially substantial areas of controversy, for instance the multiple (and conflicting) uses of the term "sustainable" and how sustainability figures into conservation strategies. The chapter discusses "new perspectives in conservation," many of which are strategies that have been discussed in conservation circles for years. The focus in the latter part of the chapter seems to be on "managing wildlife diversity," although what type of wildlife needs to be managed is not made clear. The emphasis seems to be on large mammals and other game animals, but this is not specified. The discussion of "challenges to managing wildlife diversity" presents a series of strategies for promoting conservation of biological diversity which have appeared in the conservation literature in the recent past

It is impossible to produce a book of this scope without errors creeping in, and this work is no exception. Some errors are a result of inattentive editing, such as typographical errors (some of which are quite noticeable), but others are a result of careless editing, such as a typesetting error on page 47

and captions for figures that don't match the figures. Many of the black and white photos reproduced in the book provide a valuable perspective, but there are several that are of such poor quality that they detract from the presentation more than they add. In some sections is seems that Dr. Schmidly is unsure whether his audience is professional biologists or informed amateurs. Professionals would like to see more precise use of scientific vocabulary (e.g. variation, communities, adaptation) and more documentation from the primary literature, where amateurs would prefer clear and concise descriptions of events and processes without technical jargon.

In spite of these minor criticisms, this book is a substantive contribution to our knowledge and understanding of Texas natural history, and provides a perspective on changes in the biota of Texas with applicability far beyond its borders. Because "east meets west and north meets south" in Texas, many of the changes that occurred and the processes that caused them will have occurred in other places, and the understanding of the changes and processes that this book provides will inform scientists working in those areas. Dr. Schmidly has indeed done a great service for professional naturalists in Texas and elsewhere.—*Steven Goldsmith, Department of Biology, Austin College, Sherman, TX 75090, U.S.A. sgoldsmith@austincollege.edu.*

TROPICAL DENDROLOGY IN COSTA RICA

(Field Identification of trees and shrubs)

Intensive SHORT COURSES offered EVERY YEAR since 1993

In English (March & June-July) — In Spanish (April)

March 17–29, 2003 (in English)

June 23–July 5, 2003 (in English)

Abril 14–26, 2003 (en Español)

Learn Tropical Dendrology and more about tropical forests **while traveling** over Costa Rica. Course given in **four** contrasting climatic environments **(Life Zones)**.

Highly **efficient teaching methodology developed for this course.** Course considered as the best first contact with tropical forests. References from previous students on our Website (see address below).

Course costs **US $1800.00** which includes everything while you are in Costa Rica. We offer **partial fellowships, so please contact us.**

40 Years

IN CELEBRATION OF SIDA'S 40TH YEAR OF PUBLICATION, BRIT PRESS BRINGS YOU THE LIFE OF LLOYD HERBERT SHINNERS IN HIS OWN WORDS.

Lloyd Herbert Shinners: By Himself is a biography of a man who has been described as,"one of the strongest and most interesting workers in the entire field of systematic botany in the United States."Told largely in his own words it is a story of great personal ambition and struggle. From childhood Shinners felt himself different from others and became his own critical and amused observer.

Shinners life, 1918 to 1971 spanned a particularly turbulent time in world history and in the history of botany. He was a dedicated student of both. He was the raucous defender of the romantic view of his science against the unstoppable tide of new technologies. His previously unpublished *Phylogeny in Five Dimensions* is printed here as an example of his philosophy.

The book also relates the story of Shinners' unending and self-destructive efforts to champion the cause of Botany at Southern Methodist University, where he was a professor for twenty five years. Almost single-handedly he developed and maintained its herbarium and systematics library.

This complicated, many-faceted character, this taxonomic genius who believed that nothing worthwhile was achieved without pain, found his satisfaction in working with the complexities of the Texas flora. His achievements in this field, culminating with the publication of his masterwork, *Spring Flora of the Dallas Fort Worth Area Texas*, are also part of this book.

ABSTRACT

In the course of a cladistic analysis and systematic revision of *Charianthus* (Melastomataceae: Miconieae), it was discovered that one species, *C. fadyenii* (Hook.) Griseb., is unrelated to the other members of that genus, and this species is thus reassigned to *Tetrazygia*

RESUMEN

En el curso de un análisis cladístico y revisión sistemática de *Charianthus* (Melastomataceae: Miconieae), se descubrió que una especie, *C. fadyenii* (Hook.) Griseb., no está relacionada a los otros miembros de este género y por ello es reasignado a *Tetrazygia*.

INTRODUCTION

Tetrazygia fadyenii is a very attractive melastome endemic to the Greater Antillean island of Jamaica. This species was first described by W. J. Hooker (1849) as *Tetrazygia fadyenii*. A. H. R. Grisebach (1864), misled by superficial morphological adaptations common to hummingbird-pollinated plants, transferred the species to *Charianthus* Don. The incorrect placement of this species (as *C. fadyenii* (Hook.) Griseb.) persisted through subsequent classifications and floristic treatments by Triana (1871), Cogniaux (1891), Hodge (1941), Adams (1972), and Howard (1989). Judd and Skean (1991) recognized the non-monophyletic circumscription of *Charianthus*, and transferred this species to *Miconia* sect. *Miconia*. Convergent evolution, likely driven by parallel shifts to bird pollination in *Charianthus* and *Tetrazygia fadyenii*, has resulted in the presence of relatively large, red, pseudocampanulate corollas and nectar production in both taxa. We note that J. Dan Skean, Jr. has observed hummingbirds visiting flowers of *T. fadyenii* (pers. comm.; *Skean & Samuels 1840*).

In the course of cladistic analyses of *Charianthus* based on both morphology and nuclear ribosomal ITS sequences (Penneys 2001, in prep.), it was discovered that numerous morphological and molecular synapomorphies unite

the six species of that clade. As newly circumscribed (Penneys 2001), *Charianthus* is the only plant genus endemic to the Lesser Antilles.

Additionally, *Tetrazygia fadyenii* was found to form a clade with *T. bicolor* and *T. crotonifolia* (and presumably, other species of *Tetrazygia*). Although *T. fadyenii* is currently best placed within *Tetrazygia*, ongoing investigations by the authors (and collaborators) on the phylogenetics of the Miconieae are needed to confirm this placement. The monophyly of *Tetrazygia* is supported in our preliminary analyses, but additional investigations, using more species, are needed. The monophyly of *Miconia* is doubtful, and recognition of other genera within the tribe may make *Miconia* paraphyletic, but this matter is beyond the scope of this paper.

Some morphological characters distinguishing *Tetrazygia fadyenii* from *Charianthus* and uniting it with *T. bicolor* include: the presence of druse crystals (vs. these lacking), anthers opening by terminal pores (vs. slits), a 2-loculate (vs. 4-loculate) ovary, presence of mite domatia (vs. such structures lacking), spatulate (vs. broadly ovate) petals, the calyx constricted above the ovary (vs. not constricted), an adaxial thickening of the anther base (vs. anther base non-thickened), and rounded branches (vs. flat branches) of the stellate hairs. The presence of a hypanthium strongly constricted in fruit above the ovary may be a synapomorphy for *Tetrazygia*, and is clearly evident in *T. fadyenii*. Thus, this distinctive species should again be known by its basionym, *T. fadyenii*. Its resemblance to *Charianthus* is superficial. As outlined above, these similarities presumably reflect convergent adaptations to bird pollination.

It is also of interest that the species of *Tetrazygia* occur chiefly over limestone, as does *T. fadyenii*, while the species of *Charianthus* sensu stricto grow on volcanic substrates.

Jamaica is home to four species of *Tetrazygia*, of which three are considered to be endemic (Adams 1972). This pattern of endemism is the norm for *Tetrazygia* throughout its range; the majority of species in the genus are single-island endemics. *Tetrazygia fadyenii* can be distinguished from other Jamaican members of the genus by the combination of elliptic (rarely widely elliptic or narrow obovate), essentially glabrous leaves, and bright red petals that are 9.5 to 13.5 mm long.

TAXONOMIC TREATMENT OF *TETRAZYGIA FADYENII*

Tetrazygia fadyenii Hook., Hooker's J. Bot. Kew Gard. Misc. 1:379, t. 12. 1849.

Charianthus fadyenii (Hook.) Grisebach, Fl. Br. W. Ind. Isl. 264. 1864. *Miconia fadyenii* (Hook.) W. Judd & Skean, Bull. Florida Mus. Nat. Hist. 36(2):25–84. 1991. LECTOTYPE, designated here: "*Melastoma*. Hab – [illegible] District St. Anns [sic]. This is the most beautiful plant I have seen in Jamaica. Seeds 227." Macfadyen (K, H2001/02842-1, fragment A!). ISOLECTOYPES, designated here: "Jamaica. Dr. McFadyen *Tetrazygia fadyenii*." (K, H2001/02842-2, fragment D!); "*Tetrazygia? fadyenii* Hook. Kew Journ. 1849. Jamaica. Macfadyen. Hooker 1849." (K, H2001/02842-3, fragment G!).

Nomenclatural note.—Three sheets located at K must be considered in the lectotypification of *Tetrazygia fadyenii* Hook. Each of the three sheets contain three twigs, which have been designated with consecutive letters for clarity, thus, sheet H2001/02842-1 has fragments labeled A through C, H2001/02842-2 with fragments D through F, and H2001/02842-3 with fragments G through I. All specimens designated here as lectotype material were seen by Hooker in 1849, or earlier, and were collected by MacFadyen. Proof of this is demonstrated either by their label data or by representation in the illustration of the species published by Hooker in 1849.

The BM collection H2001/02842-1 has attached to it the illustration that accompanied Hooker's description of the new species (Hooker's J. Bot. Kew Gard. Misc. 1:379, t. 12. 1849.). In that description, Hooker noted that MacFadyen provided him with specimens of the species, which he then named in his honor. This sheet also has a label, presumably written in the field by MacFadyen, that reads, "*Melastoma* sp. Hab – [illegible] District St. Anns [sic]. This is the most beautiful plant I have seen in Jamaica. Seeds 227." Written in a different hand at the top of that label is "*Charianthus* sp. nov." Fragment A, a leafy twig in fruiting condition, is here selected as the lectotype of *Tetrazygia fadyenii* Hook. This collection is from the Hooker herbarium, and was annotated by Hooker as *T. fadyenii* Hook. A fruit and seed of fragment A are represented as figures six and seven in the abovementioned illustration. Fragment B is in bud and flower, but cannot be definitively considered to have been seen by Hooker. Fragment C is a poor, sterile specimen.

Label data are completely lacking on H2001/02842-2. However, fragment D, at least, was observed by Hooker, who wrote next to that flowering twig, "Jamaica. Dr. McFadyen *Tetrazygia fadyenii*." This fragment was likely used for the habit (figure unnumbered) and flower figures two and three of the illustration cited above, which it very closely resembles, and we consider it to be an isolectotype. Fragment E is a smaller flowering twig, and F is nothing more than a scrap with five mature fruits and the date 1850. The sheet is annotated in an unidentified hand as *Charianthus fadyenii* Griseb.

From the sheet H2001/02842-3, it may be presumed that Hooker sent material of *Tetrazygia fadyenii* to Bentham as this sheet has "Herbarium Benthamianum 1854" stamps next to fragments G and I. Fragment G is a small flowering specimen overlaid by a label stating: "*Tetrazygia? Fadyenii* Hook. Kew Journ. 1849. Jamaica Macfadyen. Hooker 1849." It, therefore, appears that this fragment was included with the material originally under consideration by Hooker when he described the species. We consider it to be a possible additional isolectotype. The fruiting (and sparsely budding) twig H cannot definitively be assigned to either of the other two samples of this sheet. Fragment I is a budding twig with a label glued over it on which it is written, "Jamaica. Hooker 1843." The collec-

tor of fragment I is unknown. This sheet is annotated below as "*Charianthus fadyenii* Griseb. Triana in Linn. Trans. Vol. 28, p. 99."

Description.—Evergreen shrubs or small trees to 10 m high. Druse crystals present. Bark smooth to shallowly, longitudinally fissured; young twigs terete (slightly quadrangular), gray-brown, essentially glabrous but with a very sparse indumentum of inconspicuous, stellate and unicellular, uniseriate hairs, the stellate hairs ca. 0.09–0.13 mm in diameter, nodes (1.93–)2.13–3(–5) mm in diameter, a slightly expanded, inconspicuous interpetiolar ridge present, with inconspicuous stellate pubescence, the hairs (0.05–)0.08–0.19(–0.21) mm in diameter. Leaf blade coriaceous, elliptic (widely elliptic or narrow obovate), (3.2) 4.4–6.5(–8) cm long, (1.8–)2.2–3.1(–3.5) cm wide, blades somewhat V-shaped, margins flat (very slightly revolute), light green, yellowish-green below, with midrib, secondary veins, and margins sometimes reddish; apex acute (barely obtuse), base acute, acute cuneate or cuneate (obtuse); adaxial surface of young blades with sparse stellate hairs (some sunken in pits) and unicellular hairs, the stellate hairs (0.05–)0.08–0.19 mm in diameter, mature leaves glabrous with extremely sparse stellate and unicellular hairs, abaxial surface of young blades with few unicellular or multicellular uniseriate hairs, sometimes with very dense stellate hairs (0.05–)0.08–0.19(–0.24) mm in diameter, mature leaves appearing glabrous but with few stellate hairs, often sunken in pits and appearing as punctations (0.05–)0.08–0.24(–0.25) mm in diameter; domatia (occasionally absent) of primary-axillary hair tufts, the domatial hairs multicellular multiseriate dendritic setae, domatia (0.48–)0.56–2.34(–2.80) mm long, (0.32–) 0.33–1.47(–2.54) mm wide; margin entire; venation suprabasal (basal) with (1–) 2 pairs of secondary veins, and 1 pair of inconspicuous submarginal secondary veins, the tertiary veins very indistinct (10–)12–19(–21), intergrading with quaternary veins at base and apex; midrib and secondary veins flat to slightly impressed adaxially, tertiary and quaternary veins very indistinct adaxially, midrib raised abaxially, secondary veins slightly raised to flat abaxially, tertiary and quaternary veins flat abaxially. Petiole (0.51–)0.60–1.35(–1.80) cm long, shallowly canaliculate, often reddish, moderately stellate pubescent, with the hairs ± evenly distributed on all parts of petiole or somewhat denser abaxially, these (0.06–)0.08–0.19(–0.25) mm in diameter. Inflorescence terminal, cymose, paniculate (loosely corymbose), (3.6–)5.7–8.8(9.5) cm long, (3.4–)3.5–5.4(–5.5) cm wide, with 2–3 orders of branching, the caducous bracts to ca 3 cm long; peduncle (1.9–)2.2–2.9(–3.6) cm long, first internode above peduncle (1.03–)1.30–1.80(–2.20) cm long, first lateral internode (1–)1.1–1.7(–2.2) cm long, the flowers (21–)27–43(–76) per inflorescence. Pedicels (4.75–)5.25–7.75(–10.50) mm long, with stellate hairs (0.09–)0.11–0.16(–0.18) mm in diameter. Hypanthium cylindrical to suborbicular around ovary, tubular above ovary, (2.69–)2.75–3.60(–3.63) mm long as measured from base of hypanthium to torus, (2.07–)2.16–3.14(–3.47) mm wide, indumentum of stellate hairs, (0.05–)0.06–0.11(–0.18) mm in diam-

eter, the portion of hypanthium free from ovary (0.97–)1.11–1.38(–1.57) mm long; inner hypanthium smooth (inconspicuously ridged), torus to calyx apex length (1.72–)2.50–3.54(–3.73) mm, torus to calyx notch length (1.63–)2.19–3.27(–3.32) mm. Calyx lobes 4, (0.09–)0.16–0.53(–0.69) mm long, (2.13–)2.32–2.97(–3.13) mm wide, lobes very broadly triangular (often to such a degree that the lobes are difficult to discern), the indumentum similar to that of hypanthium, the external calyx teeth (0.25–)0.33–0.63(–0.67) mm long, usually only a blunt knob on rim of hypanthium. Petals 4, bright red, oblong spatulate, the apex truncate, (9.50–)9.88–13.13(–13.63) mm long, (3–)3.13–4(–4.31) mm wide, glabrous, many-veined, erect or slightly spreading. Stamens 8, folded adaxially in bud, in two series, isomorphic, (19–)20–21.5(–22) mm long; filaments pink, slightly tapered towards apex, 14.5–16 mm long, with proximal filament segment (0.38–)0.41–0.60(–0.67) mm wide, distal segment (0.22–)0.28–0.50(–0.53) mm wide; anthers yellow, (4.46–)4.94–5.94(–6.07) mm long, (0.53–)0.60–0.81(–0.82) mm wide, elliptic, slightly curving, opening by a single apical pore (0.19–)0.27–0.37(–0.45) mm wide. Ovary inferior, 2-loculate, (1.94–)1.97–2.94(–3) mm long, (1–)1.13–1.41(–1.87) mm wide, with an apical appendage (0.94–)0.97–1.22(–1.25) mm long, with deeply intruded axile placentation; style pink or red, straight to shallowly S-shaped, glabrous, (20.5–)21–24(–24.2) mm long, (0.38–)0.41–0.57(–0.60) mm wide; stigma not expanded, papillose. Berries globose-urceolate, 4–7 mm in diameter, urceolate, deep purple. Seeds pyramidal, 1.35–1.50 mm long, 0.75–1.03 mm wide, the testa smooth. See Figure 1 (see also Hodge 1941, *plate 6, figures 5 and 6*).

Distribution and ecology.—*Tetrazygia fadyenii* is endemic to Jamaica. It occurs on limestone hills in xeric to mesic woodlands and forest edges from 450 to 950 meters elev. where it may be locally common (Fig. 2).

Phenology.—*Tetrazygia fadyenii* has been collected in reproductive condition throughout the year, with the exception of the month of November.

Specimens examined: **JAMAICA. Illustrations of this species can be found in Hooker (1849) and Fawcett and Rendle (1910–1936). Hodge (1941) provided photos of flowers and fruits in plate six, figures five and six.

ACKNOWLEDGMENTS

We gratefully acknowledge the following individuals: Norris H. Williams and W. Mark Whitten provided vouchers and material freshly collected in silica gel that was used in the molecular analyses. Kent Perkins and Trudy Linder at FLAS kindly provided curatorial services. Thanks also to the staff at A, GH, GOET, IJ,

MO, NY, P, S, US. The authors are especially grateful to the staff of Kew for furnishing taxonomically critical specimens from their type collection.

ABSTRACT

A new combination is made for A Flora of the Chihuahuan Desert Region and for Flora of North America North of Mexico in the now more broadly constructed *Acleisanthes* (Nyctaginaceae): **Acleisanthes lanceolata** (Wooton) R.A. Levin var. **megaphylla** (Fowler & B.L. Turner) Spellenb. & J. Poole, comb. nov. This is based on evidence published recently by Levin (2000) showing that neither *Acleisanthes* nor *Selinocarpus* as traditionally treated is monophyletic, but together they form a well-defined clade in the Nyctaginaceae. We also provide a short review of the literature showing that *Commicarpus somalensis* (Chiov.) Lebrun & Stork is correctly an *Acleisanthes* (sensu lato), based on *Selinocarpus somalensis* Chiov. Due to need for consistency in level of infraspecific rank in treatments in Flora of North America North of Mexico *Abronia umbellata* Lam. subsp. *breviflora* (Standl.) Munz is recombined as **Abronia umbellata** Lam. var. **breviflora** (Standl.) L.A. Galloway, comb. et stat. nov.

RESUMEN

Se hace una combinación nueva para "A Flora of the Chihuahuan Desert Region" y para "Flora of North America North of Mexico" en el género *Acleisanthes*, ahora construido mas ampliamente: ***Acleisanthes lanceolata*** (Wooton) R.A. Levin var. ***megaphylla*** (Fowler & B.L. Turner) Spellenb. & J. Poole, comb. nov. Esta combinación resulta de la evidencia recientemente publicada por Levin (2000), demostrando que ni *Acleisanthes* ni *Selinocarpus*, como se han tratado tradicionalmente, son monofiléticos, pero juntos forman un clado bien definido en las Nyctaginaceae. También, ofrecemos citaciones bibliográficas declarando que *Commicarpus somalensis* (Chiov.) Lebrun & Stork es actualmente una *Acleisanthes* (sensu lato), basado en *Selinocarpus somalensis* Chiov. A causa de la necesidad de consistencia a nivel de categorías infraspecíficas en los tratamientos de "Flora of North America North of Mexico" *Abronia umbellata* Lam. subsp. *breviflora* (Standl.) Munz se ha recombinado como ***Abronia umbellata*** Lam. var. ***breviflora*** (Standl.) L.A. Galloway, comb. et stat. nov.

INTRODUCTION

The most recent taxonomic revisions of *Acleisanthes*, *Ammocodon*, and *Selinocarpus* have maintained the genera as distinct (Fowler & Turner 1977; Smith 1976). *Acleisanthes* (7 spp.) and *Selinocarpus* (9 spp.) have been considered distinct genera since their inception; *Ammocodon* (1 sp.) was originally described as a *Selinocarpus* (Torrey 1859). All are from arid or semi-arid regions in southwestern United States and northern Mexico, mostly on the Chihuahuan Desert or adjacent semi-arid closely allied floristic areas, except for *S. somalensis* Chiov., which occurs in northeastern Africa.

SIDA 20(3): 885–889. 2003

Recently Levin (2000), through the use of nuclear and chloroplast genes, demonstrated that *Acleisanthes* and *Selinocarpus* formed a well defined clade within the Nyctaginaceae, but individually the genera were not monophyletic. Levin (2002) then transferred those species traditionally recognized as *Selinocarpus* and *Ammocodon*, and which she recognized as valid taxa, to *Acleisanthes*. Levin did not recognize varieties in her study, considering them insignificant for her work (pers. comm. to J. Henrickson, 2002). Although the winged fruits of *Selinocarpus* and *Ammocodon* are conspicuous in their differences from the round-ribbed fruits of *Acleisanthes*, it might be inferred from Willson and Spellenberg (1977) that a change from ribbed to winged fruit is not difficult. As discussed by Levin and others, most *Acleisanthes* are herbaceous, whereas many *Selinocarpus* are suffrutescent or woody. *Ammocodon* is herbaceous. All genera produce cleistogamous flowers. In addition, *Selinocarpus diffusus* is very difficult to distinguish from *A. wrightii* vegetatively.

NOMENCLATURE

For an upcoming volume of Flora of North America North of Mexico and for A Flora of the Chihuahuan Desert Region, we are adopting Levin's interpretation of this portion of the Nyctaginaceae, recognizing those taxa traditionally called *Ammocodon* or *Selinocarpus* as *Acleisanthes*. Turner (in Turner et al. 2003) has also adopted an expanded concept of *Acleisanthes* and has made some nomenclatural transfers there. Levin (2002) made only species level nomenclatural transfers. An easily missed error occurred in her work when specific epithets were transferred in the masculine from *Selinocarpus* [masculine] to *Acleisanthes* [feminine]. Corrections necessary are considered orthographic and will be made in upcoming treatments.

Acleisanthes lanceolata (Wooton) R.A. Levin var. **megaphylla** (Fowler & B.L. Turner) Spellenb. & J. Poole, comb. nov. BASIONYM: *Selinocarpus lanceolatus* Wooton var. *megaphyllus* Fowler & B.L. Turner, Phytologia 37:181. 1977. TYPE: MEXICO. CHIHUAHUA: Jurassic gypsum ca. 15 mi SW of Estacion Moreon on Rio Conchos Lake Road, Sierra de la Monillas, 25 May 1971, *Powell 2105* (HOLOTYPE: LL; ISOTYPE: TEX!).

Acleisanthes megaphylla (Fowler & B.L. Turner) B.L. Turner in B.L. Turner et al., Atlas Vasc. Pl. Texas 7. 2003. *Selinocarpus megaphyllus* (Fowler & B.L. Turner) B.L. Turner. Phytologia 75:242. 1993.

The *Acleisanthes lanceolata* complex consists of obligate gypsophiles distributed in islandlike populations from northern New Mexico through western Texas to east-central Chihuahua. There is an irregular cline of increasing leaf width and less noticeably, perianth size, from north to south, with a more or less abrupt difference evident in populations south of the Mexico–U.S. border. *Acleisanthes lanceolata* var. *lanceolata* has lanceolate to broadly lanceolate leaves (larger leaves 5–18 mm wide), whereas *A. lanceolata* var. *megaphylla* has

ovate to round leaves (larger leaves 12–41 mm wide). In the var. *megaphylla* proportionately broadest leaves occur especially on the basal half of the stem. It is this variation that Fowler and Turner were attempting to circumscribe nomenclaturally when they described the new variety, *Selinocarpus lanceolatus* var. *megaphyllus*. Turner went even further in 1993, elevating the var. *megaphyllus* to species level as *S. megaphyllus* (Fowler & B.L. Turner) B.L. Turner and later (2003) as *Acleisanthes megaphylla* (Fowler & B.L. Turner) B.L. Turner in B.L. Turner et al. He formally recognized intermediate populations in western Texas and eastern Chihuahua as *S. maloneanus* B.L. Turner, reducing it to varietal status again in 2003 as *Acleisanthes lanceolata* var. *maloneana* (B.L. Turner) B.L. Turner. Levin (2002) lists all names in the complex that were available at the time as synonyms of *A. lanceolata*.

For A Flora of the Chihuahua Desert Region we will recognize the extremes of variation in the *Acleisanthes lanceolata* complex, which more or less correlate with geography, as two varieties in A. *lanceolata*, the var. *lanceolata* (which includes *A. lanceolata* var. *maloneana*) and var. *megaphylla*. One collection from the southern part of the range of *A. lanceolata* supports the view that these taxa better represent varieties than species. Within a single population are round-leaved plants, intermediates, and lanceolate-leaved plants, the last uncommon in the population (Mexico, Chihuahua, Mcpio. Camargo, 13.6 km W of Camargo on road to Lago Boquilla, on gypsum river terraces, 14 Aug 1974, *Spellenberg and Syvertsen 3758*, CIIDIR, IEB, MEXU, NMC [sheets 46553, 62814], TEX. So that future confusion might be avoided, two replicates of the same collection (3758) were independently prepared and accessioned at NMC several years apart, the first with the label stating distance of the site from Camargo as 8.5 miles rather than 13.6 km, the second stating the distance in kilometers).

Jim Henrickson relates to us in his review of this manuscript that the stated type locality of *Selinocarpus lanceolatus* var. *megaphyllus* is problematic. He states that Estacion Moreon is correctly Estacion Morrión. There is no Sierra de Monillas, but there is the Sierra Morrión (misspelled on Henrickson's gazetteer map [Henrickson & Straw 1976] as Sierra Gorrion). He writes in his review, "But there is a lake behind Presa Luis. L. León along the Río Conchos and there is a road to the south end of the lake about 15 mi SW of Est. Morrión and that is probably the type locality.

Acleisanthes somalensis (Chiov.) R.A. Levin: To trace the interpretation of *Commicarpus somalensis* (Chiov.) Lebrun & Stork (1989) requires access to literature difficult to obtain by those working in the Chihuahuan Desert region. We review the situation here. Lebrun and Stork, in making their new combination, examined a photograph in Chiovenda (1929, Tab. XXXIII, fig. 1) that was labeled as the type of *Selinocarpus somalensis*. The type of that taxon, however, is actually pictured in the adjacent photo (Fig. 2), labeled as *Boerhaavia*

reniformis [now considered *Commicarpus reniformis* (Chiov.) Cufod.]. The captions were switched in Chiovenda's work, as pointed out by Thulin (1994, p. 1111), misleading Lebrun and Stork. The descriptions are valid and the type is indeed a *Selinocarpus* [now as *Acleisanthes somalensis*], as indicated by the molecular data of Levin (2000).

Abronia umbellata var. **breviflora** (Standley) L.A. Galloway, comb. et stat. nov.
BASIONYM: *Abronia breviflora* Standley, Contr. U.S. Natl. Herb. 12:312, plate 30. 1909. TYPE: U.S.A. CALIFORNIA. MENDOCINO CO.: Mendocino, Jun 1989, *H.E. Brown* 833 (HOLOTYPE: US, not seen; ISOTYPE: MO!).

With little exception, the rank of variety has been used for infraspecific taxa in the Nyctaginaceae. The Flora of North America North of Mexico project requires that all infraspecific taxa within a generic treatment be at the same rank. In *Abronia*, and the Nyctaginaceae in general, the rank of variety has been most used and to continue to use rank results in the least nomenclatural disturbance. One transfer from subspecies to variety is necessary. This new combination makes the FNA *Abronia* treatment consistent, replacing *Abronia umbellata* subsp. *breviflora* (Standl.) Munz (Aliso 4:90. 1958).

ACKNOWLEDGMENTS

We thank the following: Jim Zarruchi for providing literature from the Missouri Botanical Garden regarding *Commicarpus somaliensis* and copies of relevant pages of Atlas of Vascular Plants of Texas, Neil Harriman for his opinion regarding the gender of specific epithets when transferred from *Selinocarpus* to *Acleisanthes*, Jim Henrickson and Guy Nesom for helpful comments on a draft manuscript, Roy Gereau for locating an isotype of *Abronia umbellata*, and to Leo Galloway for his patience and attention during the long process of preparing FNA Nyctaginaceae treatment. Leo Galloway has asked us to include this nomenclatural transfer in this note, thus this combination should be regarded as "L.A. Galloway in Spellenb. & Poole."

Book Review

Lincoln Taiz and Eduardo Zeiger. 2002. **Plant Physiology, Third Edition.** (ISBN 0-87893-823-0, hdbk.). Sinauer Associates, Inc., 23 Plumtree Road, P.O. Box 407, Sunderland, MA 01375. (Orders: www.sinauer.com, 413-549-1118 fax). $104.95, 690 pp., 542 illustrations, 8 1/2" × 11".

The third edition of this highly regarded undergraduate textbook has been revised, updated, and given a facelift. Though preceded by two hefty editions, this third edition is more than 100 pages shorter than the second. The authors, Tiaz and Zeiger, elected to place two chapters on a dedicated website. By using the Internet as a communication tool for some important plant physiology topics, they have included information on energy, enzymes, gene expression and signal transduction in electronic form. Clearly, the website shows the authors' willingness to keep the hard copy version of the text a workable size without compromising its content. Additionally, all figures in this latest version are in full color and subtended by captions containing a wealth of information pertinent to the chapter.

The book is generally divided into three units: *Transport and Translocation of Water and Solutes*, *Biochemistry and Metabolism*, and *Growth and Development*. The first unit begins appropriately with chapters on plant cells, water transport and balance. Other chapters included in this unit are mineral nutrition and solute transport. Unit two is filled with information on metabolic reactions. Chapters in this unit are respiration, assimilation of mineral nutrients, secondary metabolites, and three chapters on photosynthesis. Unit three has chapters on cell walls, hormones, control of flowering, stress physiology, phytochrome and light control of development.

Each chapter is subsequently broken into sections and subsections with headings. These headings would undoubtedly prove helpful for the student, since the headings are written in the form of a single sentence summary, giving the student a 'heads up' on what they are about to read.

The companion website, www.plantphys.net, not only contains two chapters not covered in the textbook, but also has a series of web topics and essays to reinforce the subject-matter covered in the text. A list of web topics and essays at the end of each chapter in the text refer to these readings on the website.

Certainly, this valuable text has been significantly improved for its third edition. The companion website is put together well and is surely an indication of the fate of future textbooks. *Plant Physiology* has clearly set a standard in college science texts and the authors are to be commended for their revisions and editorial work. Without doubt, this book should be a standard text in botany and biology departments.—*Amy Trauth Nare, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX, 76102 U.S.A., amy_trauth@yahoo.com.*

YUCCA CERNUA (AGAVACEAE: SERIES RUPICOLAE), A NEW SPECIES FROM NEWTON AND JASPER COUNTIES IN EASTERN TEXAS

Eric L. Keith

Raven Environmental Services Inc.
P.O. Box 6482
Huntsville, TX 77342, U.S.A.
eric.keith@excite.com

ABSTRACT

A new species of *Yucca* from the series Rupicolae is described from Jasper and Newton counties in eastern Texas. Series Rupicolae is distinguished by its characteristically denticulate leaves and beaked fruits. This new species, *Yucca cernua*, sp. nov. is described, illustrated, and distinguished from other acaulescent species in ser. Rupicolae. The combined characteristics of a tall flowering scape; the tendency of the branches of the inflorescence to recurve and droop as they lengthen; the moderately to densely floccose inflorescence; large leaves typically growing erect; relatively short capsules, pistils, and stamens; unique habitat; and disjunct distribution distinguish this species from other acaulescent species in ser. Rupicolae. The rarity of this species warrants its consideration as a candidate for state and federal regulatory protection. Also included is a key of the entire or denticulate, non-filiferous leaved North American species of *Yucca*.

RESUMEN

Se describe una nueva especie de *Yucca* de la serie Rupicolae de los condados Jasper y Newton en el Este de Texas. La serie Rupicolae se distingue por las hojas denticuladas y frutos picudos. Esta nueva especie, *Yucca cernua* sp. nov., se describe, se ilustra y diferencia de las otras especies de la serie Rupicolae. Un conjunto de varias características distingue esta especie de las otras especies acaulescentes de la serie Rupicolae. Estas características son la presencia de un escapo alto con flores, la tendencia de las ramas de la inflorescencia a retorcerse y colgar cuando se alargan, la inflorescencia de mediana a densamente flocosa, cápsulas, pistilos y estambres relativamente cortos, las hojas grandes que típicamente se desarrollan de forma erecta, un hábitat único, y su distribución disyunta. La rareza de esta especie justifica su consideración como candidata para la regulación de protección estatal y federal. También se incluye una clave de todas las especies de Yucca norteamericanas con hojas denticuladas y filíferas.

In May of 2001, an unusual population of *Yucca* was discovered along U.S. Highway 190 in Newton County, Texas. It appeared distinctive because of its tall inflorescence (up to four meters) and the characteristic tendency of the inflorescence branches to recurve and droop as they lengthened. On closer investigation, these plants appeared most similar to *Y. pallida* McKelvey with mostly flat, glaucous, denticulate leaves. No plants were collected because the significance of the population was not recognized at the time. Plants were later collected in flower in June of 2002 and in fruit in November of 2002. It was unknown whether this population was escaped from cultivation, disjunct, or represented

SIDA 20(3): 891–898. 2003

an undescribed species. After examination of live plants and numerous herbarium specimens of its apparent closest relatives, it was determined to represent a new species. Acronyms of the herbaria cited follow Index Herbariorum (Holmgren et al. 1998).

Yucca cernua Keith, sp. nov. (**Figs. 1, 2**). TYPE: U.S.A. TEXAS. NEWTON CO.: brown, clayey roadside on US Hwy 190, 3/8 mi E of Newton-Jasper County line, plants ranging from 1.5–4 m tall, branches of inflorescence drooping with age, 11 Jun 2002, *Eric L. Keith* 183 (HOLOTYPE: TEX; ISOTYPES: BRIT, SHSU).

A Yuccae pallidae ac Yuccae rupicolae similis fructibus rostratis et marginibus serrulatis foliorum; ab utroque differt inflorescentia elatiore (usque ad 4 m) ramis moderate vel dense floccosis recurvantibus ac cernuentibus simul elongentibus, foliis majoribus (usque ad 80 cm longis ac 6.5 cm latis), pistillis brevioribus (2–2.7 cm), et staminibus brevioribus (1.2–1.7 cm).

Acaulescent, forming large solitary clumps and spreading from thick rhizomes, 1–2 cm diameter. ***Leaves*** (30–)40–70(–80) cm long, (3–)3.5–6.5 cm wide at widest point, greatly narrowed (0.7–1.2 cm) to just above union with base, young leaves glaucous, the lowermost leaves usually undulate and twisting, older leaves becoming yellowish-green to olive green and flat or slightly concave, turning purplish or brown on drying, acute or slightly acuminate, becoming concave and inrolled 0.7–2.5 cm below tip; leaf margins corneous, yellowish and minutely denticulate; spines, 0.3–1 cm long, pungent, yellowish at base and reddish-brown at tip. Inflorescence long-exserted, (1.5–) 2–4 m tall, scape (1.2–)1.5–3.2 m in length; inflorescence panicled, moderately to densely floccose, branched from base to racemose tip; inflorescence branches characteristically recurved and drooping as they lengthen, longest branches to 35 cm long. ***Flowers*** mostly white or slightly greenish white, campanulate, pendant; tepals free, glabrous, outer whorl narrowly elliptic or lanceolate, 3.4–5(–5.8) cm long, 0.75–1.7 cm wide, inner whorl elliptic 3.5–5(–5.8) cm long and 1–1.8 cm wide; stamens 1.2–1.9(–2.2) cm long; filaments reflexed or even slightly twisted or contorted especially on drying, echinate; anthers to 0.7 mm long, sagittate; pistil 2–3 (–3.3) cm long as measured from base of ovary to tip of stigmas; ovary slender, oblong-cylindric, 0.4–0.8 cm diameter; styles 3, 0.8–1.5(–1.7) cm long, erect to slightly spreading, branches usually papillose. ***Fruit*** dry, dehiscent, pendant, 3.2–4.5 cm long, 2–2.5 cm in diameter, symmetrical, oblong-cylindric, at dehiscence splitting for entire length on primary fissures and usually $^1/_4$ to $^1/_2$ of the length of capsule on secondary fissures; beaks 0.5–1 cm in length, usually turned inward at 45° angles where split on secondary fissures (Fig. 1). ***Seeds*** polymorphic, obovate to D-shaped 5–7 mm long and 4–6 mm wide, thicker toward edges, 0.5–1 mm thick.

Etymology.—The epithet refers to the characteristic tendency of the inflorescence branches to recurve and droop as they lengthen, an apparently distinctive feature separating it from all other *Yucca* species.

Habitat and Distribution.—*Yucca cernua* occurs in open or slightly shaded

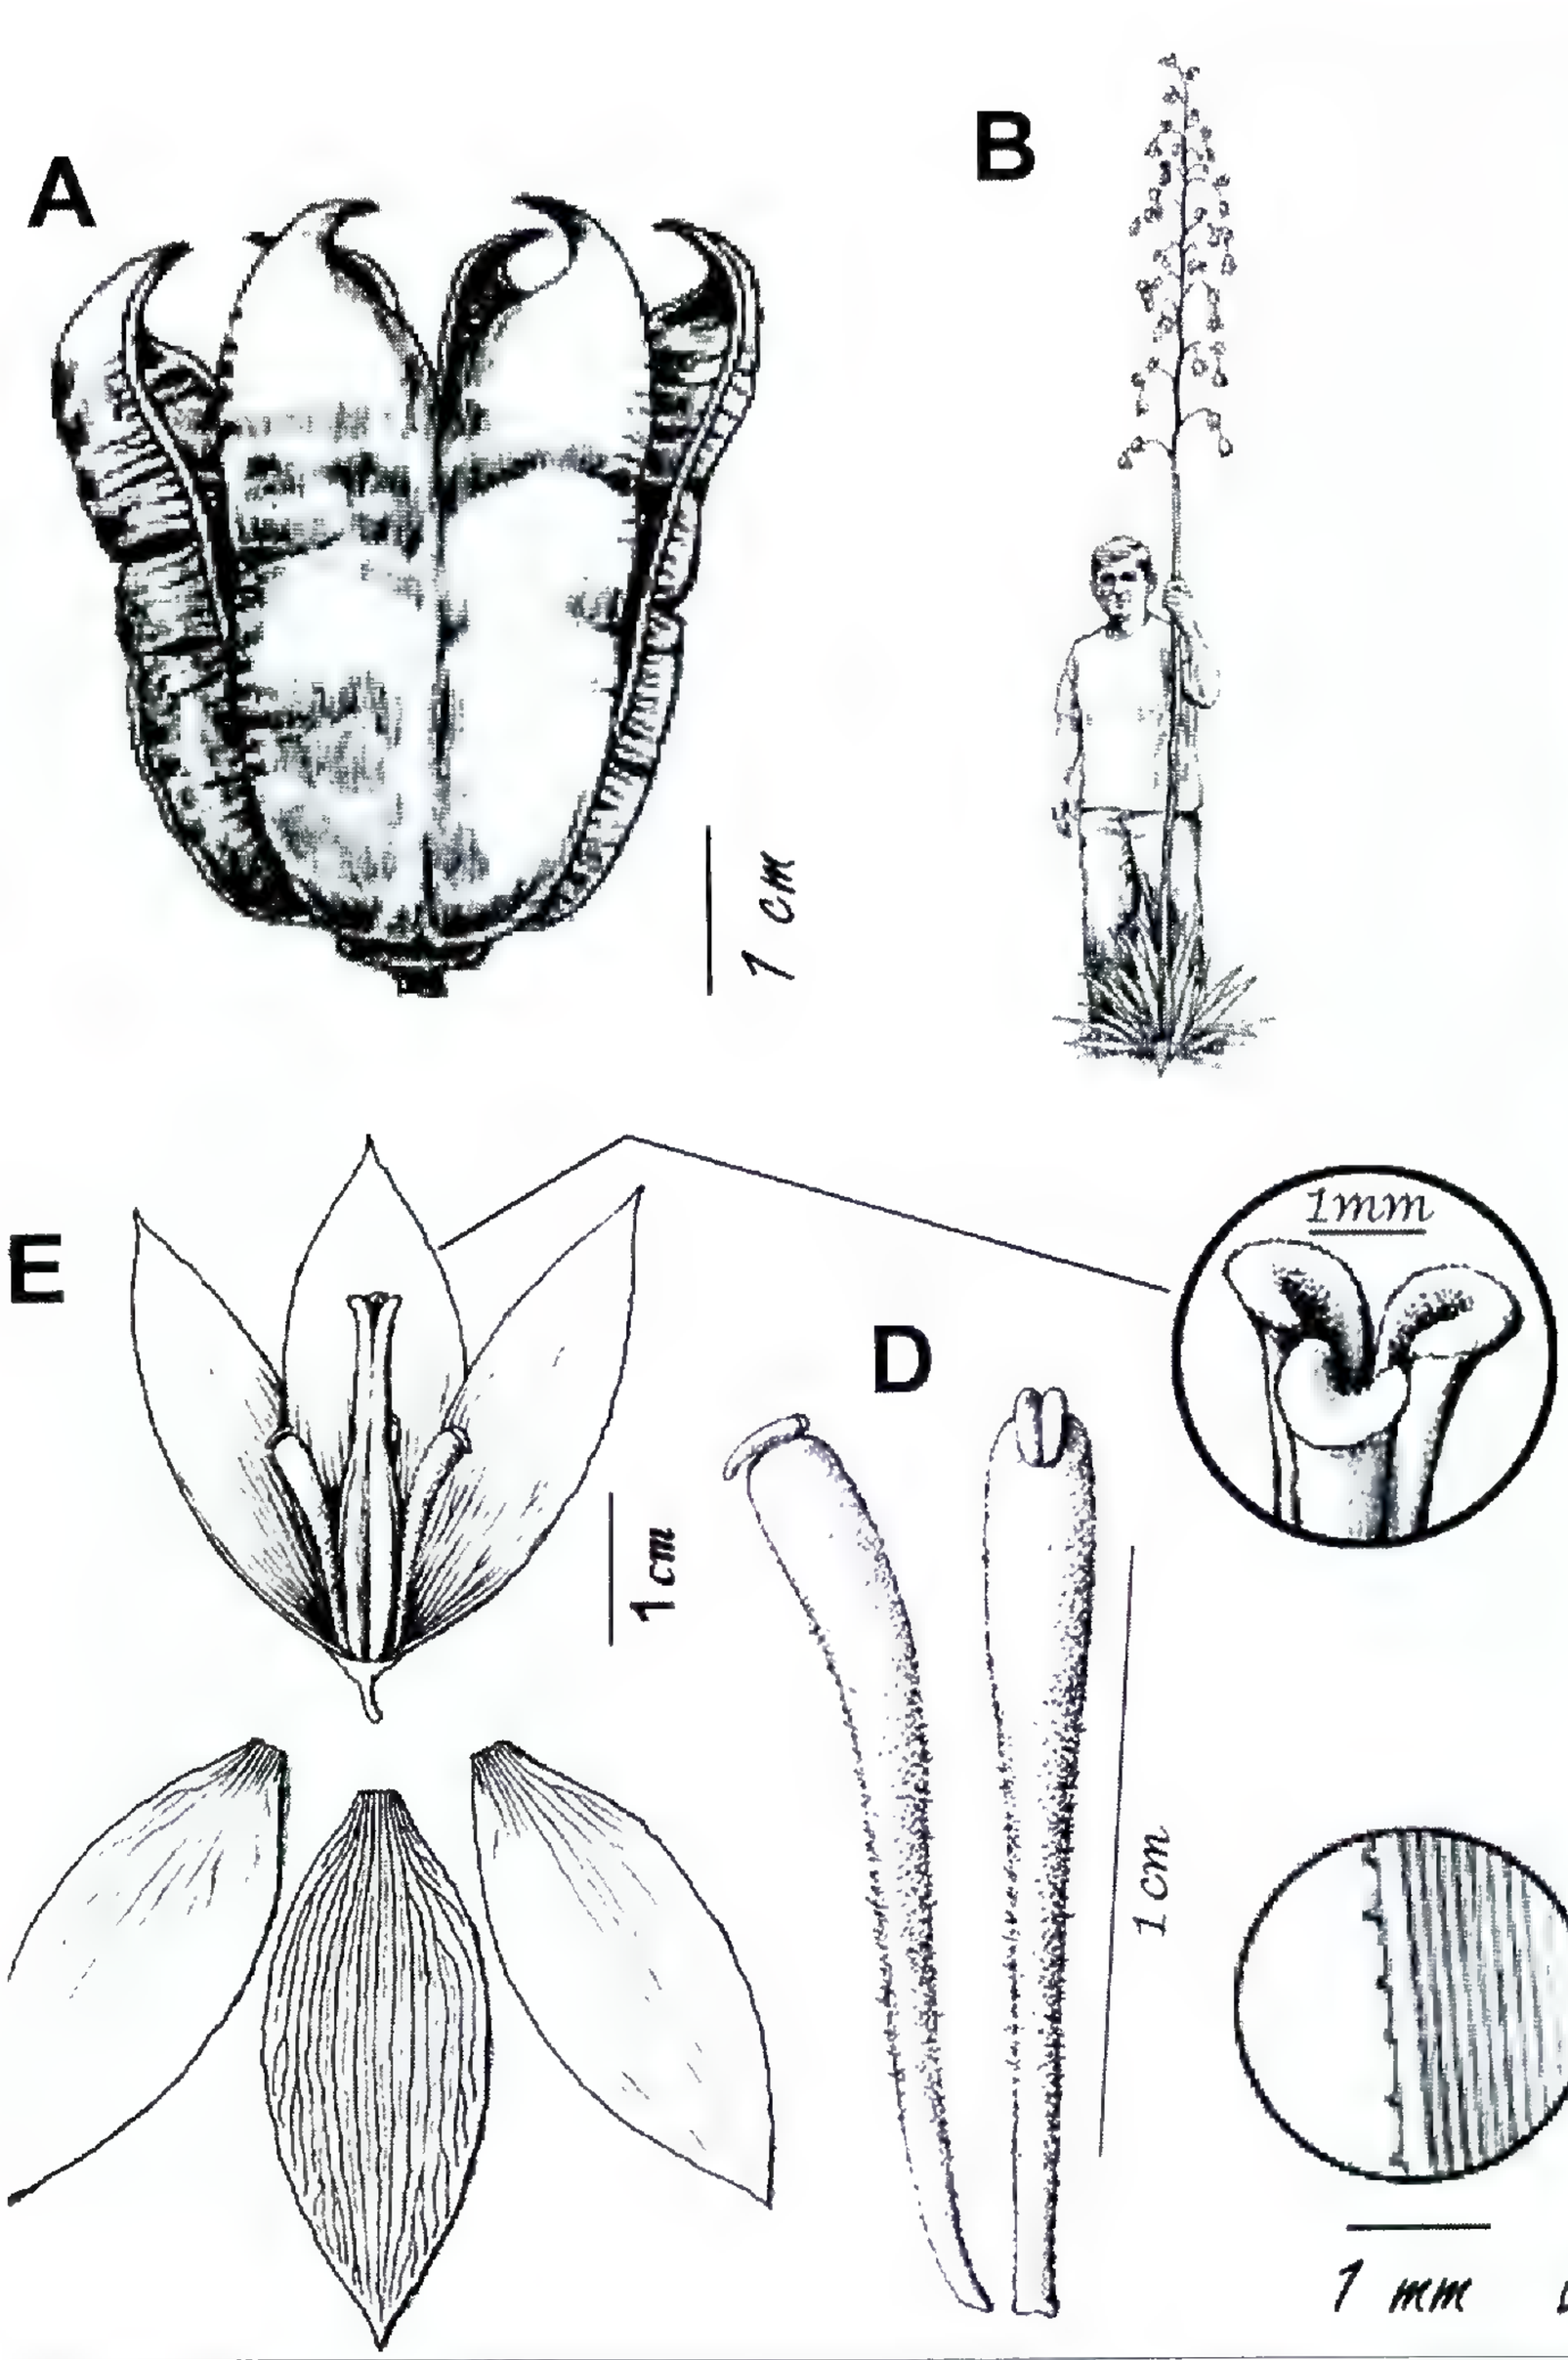

FIG. 1. *Yucca cernua*. **A.** Capsule. **B.** Habit. **C.** Representative leaf, abaxial surface, with leaf margin magnified 11×. **D.** Stamen, front view and side view, slightly enlarged. **E.** Flower; inset detail of stigma lobes.

areas apparently restricted to brownish, acidic clayey soils of the Redco Soil Series in Jasper and Newton counties in eastern Texas (Neitsch 1982). The Redco Soil Series occurs in southeastern Texas from Newton County westward to Walker County (McClintock 1979; Neitsch 1982; USDA 2002). This species is currently known only from an area approximately 6-km^2 centered in west-central Newton County and just into the far eastern portion of Jasper County. One large population of approximately 1000 plants and six small populations

FIG. 2. *Yucca cernua* Keith. **A.** Young leaves glaucous. Note lower leaves slightly undulate and twisting. **B.** Older leaves yellowish-green or olive and flat. **C.** Inflorescence recurved and drooping. **D.** Habit.

of less than a 100 plants each are known. In 1987, Thomas and Allen collected this species (labeled as *Yucca* sp.) at the type locality. A 1951 collection of *Y. cernua* (labeled as *Yucca*) at the Botanical Research Institute of Texas (BRIT) from Jasper County indicates that it was collected in the town of Jasper. This population, if still extant, is at least five miles west of any known location. No other collections of this species are known. This species is apparently tolerant of soil disturbance. All of the plants are found along roadsides and other disturbed areas, and it rapidly colonizes areas with bare soil. It is hoped that more populations will be found throughout southeastern Texas in similar habitats.

Associated species.—*Eurybia hemisphaerica* (Alexander) Nesom, *Helianthus angustifolius* L., *Panicum anceps* Michx., *Solidago canadensis* L., *Tridens strictus* (Nutt.) Nash, *Smilax bona-nox* L., *Pinus taeda* L., *Symphyotrichum lateriflorum* (L.) A.&D. Löve, *Symphyotrichum dumosum* (L.) Nesom, *Carex flaccosperma* Dewey, *Liquidambar styraciflua* L., *Ilex vomitoria* Ait., and *Coreopsis* sp.

Additional collections examined: U.S.A. **TEXAS. Jasper Co.:** Jasper, leaves up to 69 cm long and 4 cm broad; terminal spine 5–7 mm long, 20 Jul 1951, *H.R. Reed 1238* (BRIT). **Newton Co.:** on S side of U.S. 190, 8.8 mi E of Texas 63 intersection near Jasper and 4.3 mi W of Newton, Texas, top of dry, sandy hill on S side of U.S. 190, 07 Sep 1987, *R. Dale Thomas & Charles M. Allen 101823* (NLU).

Yucca cernua is a very distinctive species adapted to a unique soil type. It appears to be closely related to *Y. pallida* and *Y. rupicola* Scheele in the series Rupicolae and which it most closely resembles by its acaulescent habit, denticulate leaves, and beaked capsules (Hess & Robbins 2002; McKelvey 1947; Trelease 1902). The closest known populations of either species are over 300 km to the west and northwest of *Y. cernua* (Correll & Johnston 1970; Diggs et al. 1999; Hochstaetter 2000; McKelvey 1947).

Table 1 provides a list of the major differences between these three species. To date, our understanding of the species indicates that it is endemic to this region and is extremely rare. Adverse impacts to this population described above could pose serious threats to the continued existence of the species. All known populations of *Yucca cernua* are found on private land and public highway rights-of-way and are not currently protected. Fortunately, a preliminary agreement with a private landowner will set aside a preserve along both sides of Highway 190 where the largest population occurs. Since this species appears to have a very restricted distribution based on unique soil requirements, it should be considered as a candidate for federal and state protected species status.

Included herein is a key of the entire or denticulate, non-filiferous leaved North American species of *Yucca*. Key is derived from Hess and Robbins (2002) and personal observations.

1. Mature plants caulescent; rosettes each with more than 100 leaves; distribution in western Texas.
   2. Mature plants 2.5–3.6 m, not including inflorescence; leaf blade 25–60 × 1.2–1.7 cm, widest considerably above middle, smooth _____ **Yucca rostrata**

TABLE 1. A comparison of *Yucca cernua*, *Yucca pallida*, and *Yucca rupicola*. Characters are taken from personal observations, Diggs et. al (1999), Hess and Robbins (2002), and McKelvey (1947).

Feature	*Yucca cernua*	*Yucca pallida*	*Yucca rupicola*
Distribution	Jasper and Newton counties in eastern Texas	Central Texas northward to North Central Texas	Edwards Plateau
Habitat	Acidic clays of the Redco Soil Series	Open areas on limestone outcrops	On limestone ledges and plains
Leaf dimensions	(30–)40–70(–80) cm long, (3–)3.5–6.5 cm wide at widest point	18–35(–56) cm long, (1.0–) 2.5–3.2(–4.5) cm wide at widest point	25–60(–82) cm long, (1.7–) 2.3–5(–6) cm wide at widest point
Leaf characteristics	Most leaves flat except green lowermost leaves which are usually undulate and twisted, young leaves glaucous becoming olive or yellowish with age	Most leaves flat and persistently blue-green glaucous	Most leaves olive-green and undulate and twisted
Spine characteristics	Yellow at base, reddish brown at tip	Mostly all yellow, occasionally slightly reddish near base	Orange, yellowish-brown, or reddish-brown
Inflorescence height	(1.5–)2–4 m tall	1.3–2.5 m tall	1.5–3.6 m tall
Inflorescence characteristics	Moderately to densely and floccose, branches recurved and drooping	Glabrous and glaucous, branches wide-spreading	Glabrous or slightly pubescent, branches erect-ascending
Tepal dimensions	3.4–5(–5.8) cm long, 0.75–1.8 cm wide	(3.6–)5 -6.5 cm long, (1.5–) 2–3.2 cm wide	(4–)5.5–8.2 cm long, (1.4–) 2–3.2 cm wide
Pistils **Stamens** **Capsules**	2–3(–3.3) cm long 1.2–1.9(–2.2) cm long 3.2–4.5 cm long	2.4–4 cm long 2.1–3.2 cm long 3.8 5 cm long	2.7–4 cm long 1.8–2.8 cm long 4.8–7.5 cm long
Capsule beaks	0.5–1 cm long, usually turned inward at 45° angles where split on secondary fissures	0.8–1.2 cm long, usually erect	0.9–1.2 cm long, erect or slightly reflexed

2. Mature plants 0.7–2.5 m, not including inflorescence, leaf blade 20–30(–45) × 0.7–1.2 cm, widest at or above middle, ± scabrous _____ **Yucca thompsoniana**

1. Mature plants acaulescent, usually forming colonies; rosettes each with fewer than 100 leaves.
   3. Mature leaf blade undulate and twisted, strongly concave, margins orange or yellowish-brown to reddish-brown; endemic to eastern Edwards Plateau _____ **Yucca rupicola**
   3. Mature leaf blade straight (lowermost leaves usually twisted in. *Y. cernua*), flat or slightly concave, margins yellow or reddish brown.
      4. Mature leaf blades 1–2(–2.5) cm at greatest width, inflorescence densely floccose with branchlets spreading or ascending; endemic to western Edwards Plateau _____ **Yucca reverchonii**
      4. Mature leaf blades (1–)2.5–6.5 cm at greatest width, inflorescence either moderately to densely floccose with recurved and drooping branchlets or glabrous with wide-spreading branchlets.
         5. Plants in colonies of 10–30 rosettes each, leaves (1–)2.5–3.2(–4.5) cm at greatest width, persistently blue-green glaucous, inflorescence glabrous with wide-spreading branchlets; endemic to central and north-central Texas _____ **Yucca pallida**
         5. Plants usually solitary, leaves (3–)3.5–6.5 cm at greatest width, young leaves glaucous becoming olive or yellowish-green with age, inflorescence floccose with recurved and drooping branchlets; apparently endemic to eastern Texas _____ **Yucca cernua**

ACKNOWLEDGMENTS

I would like to thank Karen Clary of Austin, Texas for all her advice and encouragement, for sharing her expertise on *Yuccas*, and for critical review of the paper. William J. Hess also gave critical review of the paper and offered helpful suggestions. I would also like to thank Guy Nesom of the Botanical Research Institute of Texas (BRIT) for all his help and for providing the Latin diagnosis. University of Texas Herbarium curator Tom Wendt, interim collections manager Amy Trauth Nare at BRIT, and Justin Williams at Sam Houston State University kindly allowed me to use the collections and were very helpful. In addition, I examined *Yucca* loan material at TX/LL from A, ARIZ, BAY, DS, GA, GH, MO, NLU, NY, TAES, TX, UC and US.

I give special thanks to my botany professors at Stephen F. Austin State University, Elray Nixon and James Van Kley, for instilling my interest in plant taxonomy and ecology and to Larry Brown of Houston Community College and Spring Branch Science Center for his enthusiastic tutelage on the flora of Texas.

I also thank my co-workers, Ross Carrie and Kevin Mundorff, for their assistance including critical review of the paper. Richard Lane of the Huntsville Public Library and Vinessa Mundorff of Sam Houston State University were also very helpful in acquiring most of my reference material.

Most of all, I would like to thank my family for all their love, support, and patience during my botanical pursuits including my wife, Elizabeth (who also edited the paper), and two sons, Lance and Will. My father, William Keith of

Lufkin, Texas, provided the Spanish translation of the abstract, and my uncle, Larry Keith of Houston, Texas, provided the illustrations.

ABSTRACT

Two new species of *Parathesis*, *P. pseudocalophylla* Ricketson & Pipoly from Chiapas, Mexico, and *P. pseudocrassiramea* Ricketson & Pipoly from San José, Costa Rica, are described and illustrated. Further revision of the genus has revealed the necessity of neotypifying *P. rothschuhiana* Mez.

RESUMEN

Se describen y se ilustran dos especies nuevas pertenecientes al género *Parathesis*, *P. pseudocalophylla* Ricketson et Pipoly, y *P. pseudocrassiramea* Ricketson et Pipoly, provenientes de Chiapas, México y San José, Costa Rica. Además, se neotipifica *P. rothschuiana* Mez.

The genus *Parathesis* (A. DC.) Hook. f. contains 95 species distributed from northern Mexico to Panama, the Caribbean, and throughout the Andes from Venezuela to Bolivia and adjacent Brazil. The genus is defined by the unique glandular papillae of the corolla lobes, and bright yellow anthers. In preparing the treatment of the genus *Parathesis* for *Flora Mesoamericana*, two new species were discovered, and are described herewith.

Parathesis pseudocalophylla Ricketson & Pipoly, sp. nov. (**Fig. 1**). TYPE: MEXICO. CHIAPAS: Mpio. La Independencia, third ridge along logging road from Las Margaritas to Campo Alegre, 2,300 m, 3 Jul 1981 (fl.), *D. Breedlove 51314* (HOLOTYPE: MO; ISOTYPES: CAS, LL).

Quoad laminam bullatam inflorescentiam lateralem *P. calophyllae* valde affinis, sed ab ea ramulis pedunculis laminisque rigide rufo (non adpresse ferrugineo-) arachnoideo- dendroideo-tomentosis, petiolis 0.7–1.5 (non 2.8–3.4) cm longis, calyce 1.6–1.8 (non 2.2–2.4) mm longo, corolla 6.1–6.3 (non 7.2–7.5) mm longa, atque staminium 4.5–4.7 (non 4.3–4.5) mm longarum, filamentis 2.9–3.1 (non 2.5–2.7) mm longis, ac antheris lanceolatis (non ovatis) 2–2.2 (nec 1.8–2.1) mm longis statim separabilis.

Trees to 6.1 m tall. ***Branchlets*** slender, angulate, 3–6 mm in diam., densely and stiffly rufous arachnoid and dendroid tomentose. ***Leaves***: with blades chartaceous to subcoriaceous, elliptic, 8.8–14.4 cm long, 2.2–4.7 cm wide, apically acuminate, the acumen 0.6–1.6 cm long, basally acute, decurrent on the petiole, conspicuously and prominently punctate and punctate-lineate, glabrous above except scattered to densely rufous dendroid tomentose at the base and along the midrib, with scattered arachnoid and dendroid trichomes below

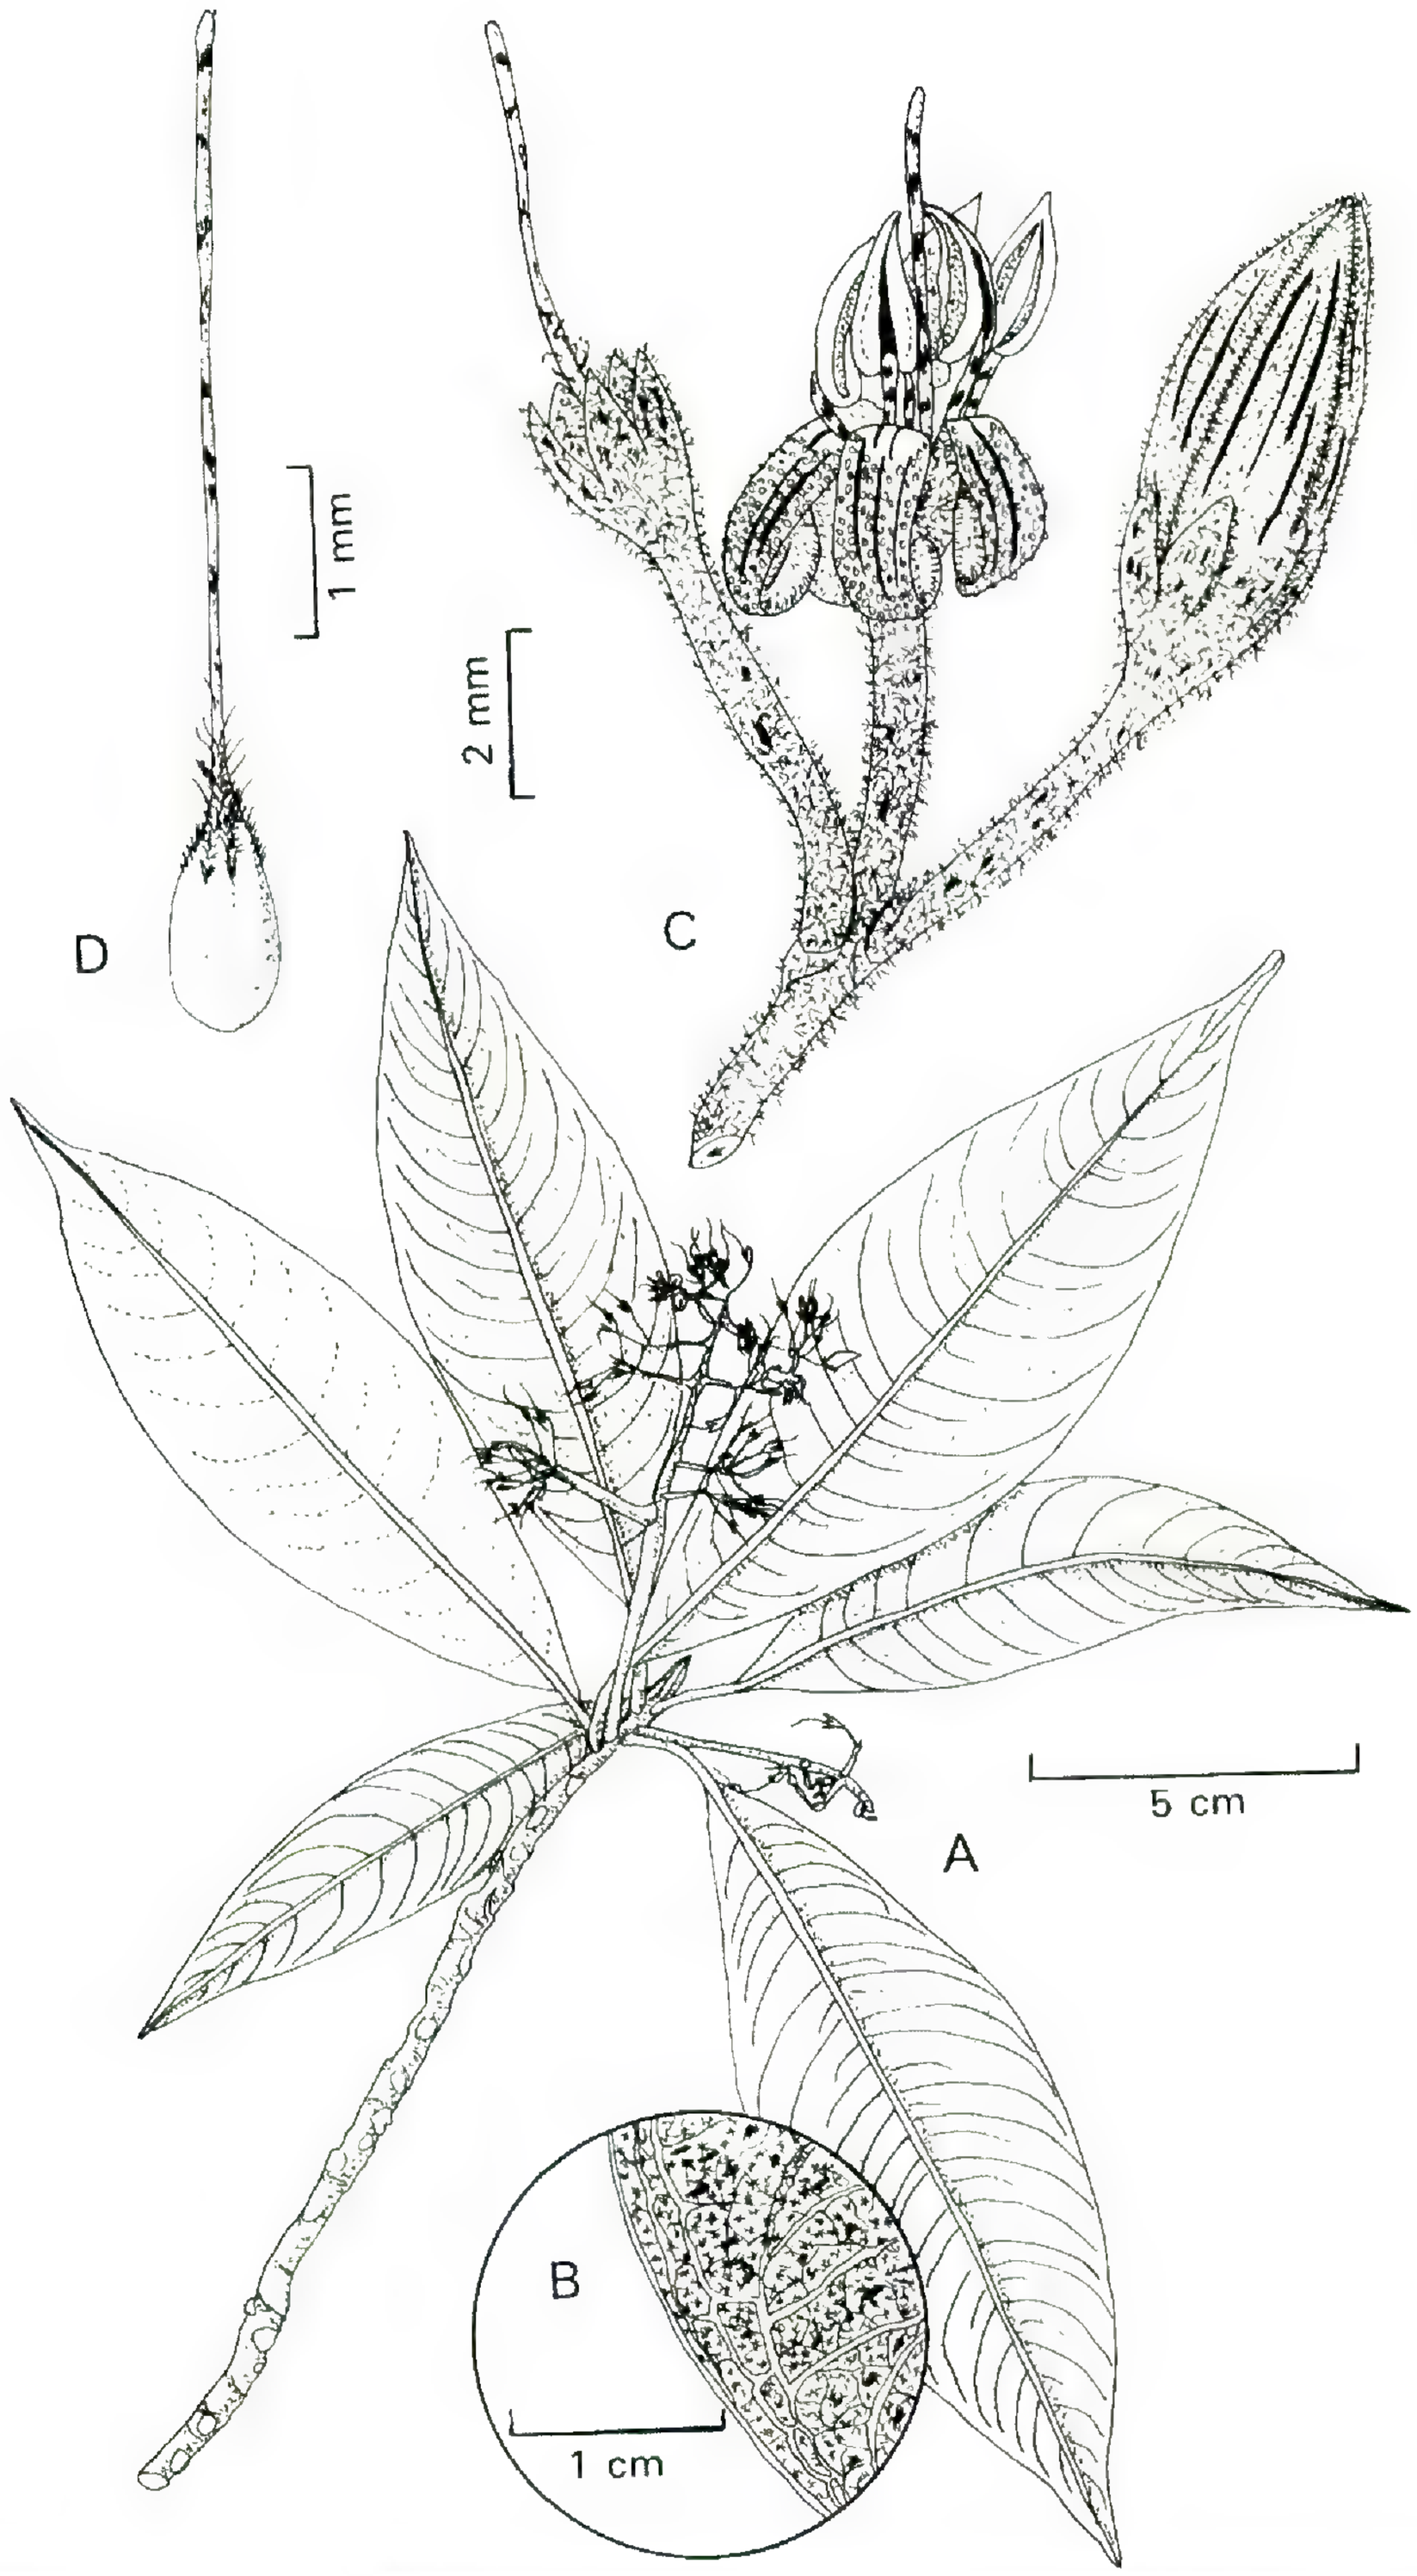

FIG. 1. *Parathesis pseudocalophylla* Ricketson & Pipoly. **A.** Flowering branch. **B.** Detail of abaxial leaf surface. **C.** Detail of inflorescence. **D.** Pistil. A–D drawn from holotype, *D. Breedlove 51314* (MO).

except densely so along the midrib, the midrib impressed above, prominently raised below, the secondary veins 20–27 pairs, slightly bullate above, prominently raised below, the margins entire; petioles slender, marginate, 0.7–1.5 cm long, vestiture as in the branchlets. ***Inflorescences*** lateral, pinnate to bipinnately paniculate, 3.5–9.5 cm long, 2–5 cm wide, pyramidal, shorter than the leaves, the rachis with a vestiture as in the branchlets, the branches 3–7-flowered corymbs; peduncles 2.2–5.1 cm long; inflorescence bracts unknown; inflorescence branch bracts caducous, membranous, ovate to lanceolate, 1.8–2.1 cm long, 0.7–0.9 mm wide, apically acute, conspicuously and prominently punctate and punctate-lineate, glabrous adaxially, densely arachnoid and dendroid tomentose abaxially, the veins inconspicuous, the margins entire; floral bracts similar to the inflorescence branch bracts but, 0.9–1.6 mm long, 0.3–0.5 mm wide; pedicels slender, angulate, 4.3–5.5 mm long, conspicuously and prominently punctate and punctate-lineate, vestiture as in the branchlets. ***Flowers*** 5-merous; calyx chartaceous, 1.6–1.8 mm long, the tube 0.3–0.5 mm long, the lobes ovate, 1.1–1.3 mm long, 0.8–1 mm wide, apically acute, conspicuously and prominently punctate and punctate-lineate, glabrous within, scattered to densely pubescent with simple trichomes, the margins entire; corolla pink, chartaceous, 6.1–6.3 mm long, the tube 0.6–0.8 mm long, the lobes lanceolate, 5.4–5.7 mm long, 1.2–1.5 mm wide, apically attenuate, conspicuously and prominently punctate and punctate-lineate, glandular-papillose within except glabrous at the very base, scattered to densely pubescent with simple trichomes, the margins entire; stamens 4.5–4.7 mm long, the filaments 2.9–3.1 mm long, the staminal tube 0.7–0.8 mm long, the apically free portion 2.1–2.3 mm long, conspicuously and prominently punctate and punctate-lineate, glabrous, the anthers yellow, erect, basifixed, lanceolate, 2–2.2 mm long, 0.7–0.9 mm wide, apically acute, apiculate, basally cordate, the connective conspicuously and prominently punctate and punctate-lineate; pistil 5.9–6.2 mm long, the ovary ovate, 1.1–1.3 mm long, inconspicuously punctate and punctate-lineate, glabrous except apically of scattered to densely villous or pilose of simple multicellular trichomes, the style 4.7–4.9 mm long, conspicuously and prominently punctate and punctate-lineate, glabrous except basally with scattered to densely villous or pilose of simple multicellular trichomes, the ovules 6–8, uniseriate. ***Fruits*** unknown.

Distribution.—*Parathesis pseudocalophylla* is only known from the type collection, between Las Margaritas to Campo Alegre, in the Mpio. of La Independencia, Chiapas, Mexico, growing at 2300 m elevation.

Ecology and conservation status.—*Parathesis pseudocalophylla* occurs in evergreen cloud forests, with *Pinus*, *Quercus*, *Magnolia*, *Podocarpus*, *Photinia* and *Olmediella*. Because it was collected along a logging road, it should be considered threatened.

Etymology.—The specific epithet comes from it close affinity to *Parathesis calophylla*.

Parathesis pseudocalophylla was at first confused with *P. calophylla* because of the chartaceous to subcoriaceous, slightly bullate leaves, and lateral inflorescences. However, *P. calophylla* has densely appressed ferrugineous arachnoid or dendroid trichomes forming a tomentum, while in *P. pseudocalophylla*, the hairs are erect, stiff and rufous. In addition, *P. pseudocalophylla* has shorter petioles and perianth parts, but significantly longer stamens to 4.7 mm long, and larger lanceolate instead of ovate anthers to 2.2 × 0.9 mm.

Parathesis pseudocrassiramea Ricketson & Pipoly, sp. nov. (**Fig. 2**). TYPE. COSTA RICA. SAN JOSÉ: Cantón de Pérez Zeledón, Parque Nacional Chirripó, Cuenca Térraba-Sierpe, Estación Santa Elena, 09° 23' 36" N, 083° 35' 21" W, 1,300–1,400 m, 17 Sep 1997 (fr.), *E. Alfaro 1431* (HOLOTYPE: INB; ISOTYPES: CR, MO).

Ob laminam bullatam inflorescentiam terminalem necnon ovarium dense adpresseque tomentosum *P. crassirameae* valde affinis, sed ab ea ramulis 8–10 (non 2–5) mm diametris minute papilloso- vel glandulari-granuloso- (non multicellulo- vel stellato-) tomentosis, lamina foliari 18–25 (non 5.8–18.2) cm longa, 7.9–10.5 (nec 1.8–6.3) cm lata, ad apicem acumine 1–1.8 (nec 0.3–1) cm longo, calyce 1.2–1.7 (non 1.7–1.9) mm longe, antheris 1.5–1.8 (non 2.2–2.4) mm longis perfacile recognoscitur.

Trees 6 m tall. ***Branchlets*** stout, angulate, 8–10 mm in diam, densely appressed papillose- or glandular-granulose-tomentose, glabrescent with age. ***Leaves***: with blades coriaceous, elliptic to oblong, 18–25 cm long, 7.9–10.5 cm wide, apically obtuse, abruptly acuminate, the acumen 1–1.8 cm long, basally obtuse to rounded, decurrent on the petiole, bullate, conspicuously and prominently punctate and punctate-lineate, glabrous above, essentially glabrous below but with sparse papillae or glandular granules at the very base, the midrib impressed above, prominently raised below, the secondary veins 80–110 pairs, conspicuously impressed above, prominently raised below, the margins entire, enrolled; petioles slender, marginate, 2.8–3.6 cm long, glabrous above, appressed papillose- or glandular-granulose-tomentose below, glabrescent with age. ***Inflorescences*** terminal and in the axils of the uppermost leaves, pinnate to bipinnately paniculate, 27–28 cm long, 22–25 cm wide, pyramidal, as long or longer than the leaves, the rachis tomentose as in the branchlets, the branches 3–7-flowered corymbs; peduncles nearly absent to 1 cm long, the lower branches subtended by leaves; inflorescence bracts unknown; inflorescence branch bracts unknown; floral bracts caducous, membranous to chartaceous, ovate, 0.9–1.5 mm long, 0.5–1 mm wide, apically acuminate, basally sessile, conspicuously and prominently punctate and punctate-lineate, glabrous adaxially, vestiture as in the branchlets abaxially, the veins inconspicuous, the margins entire; pedicels stout, angulate, 1–2.5 mm long, conspicuously and prominently punctate and punctate-lineate, vestiture as in the branchlets. ***Flowers*** 5- to 6-merous; calyx chartaceous, 1.2–1.7 mm long, the tube 0.2–0.4 mm long, the lobes ovate, 0.9–1.5 mm long, 1–1.4 mm wide, apically long acuminate, conspicuously and prominently punctate and punctate-lineate, glabrous within, vestiture as in the branchlets, the margins entire; corolla color unknown, chartaceous to coria-

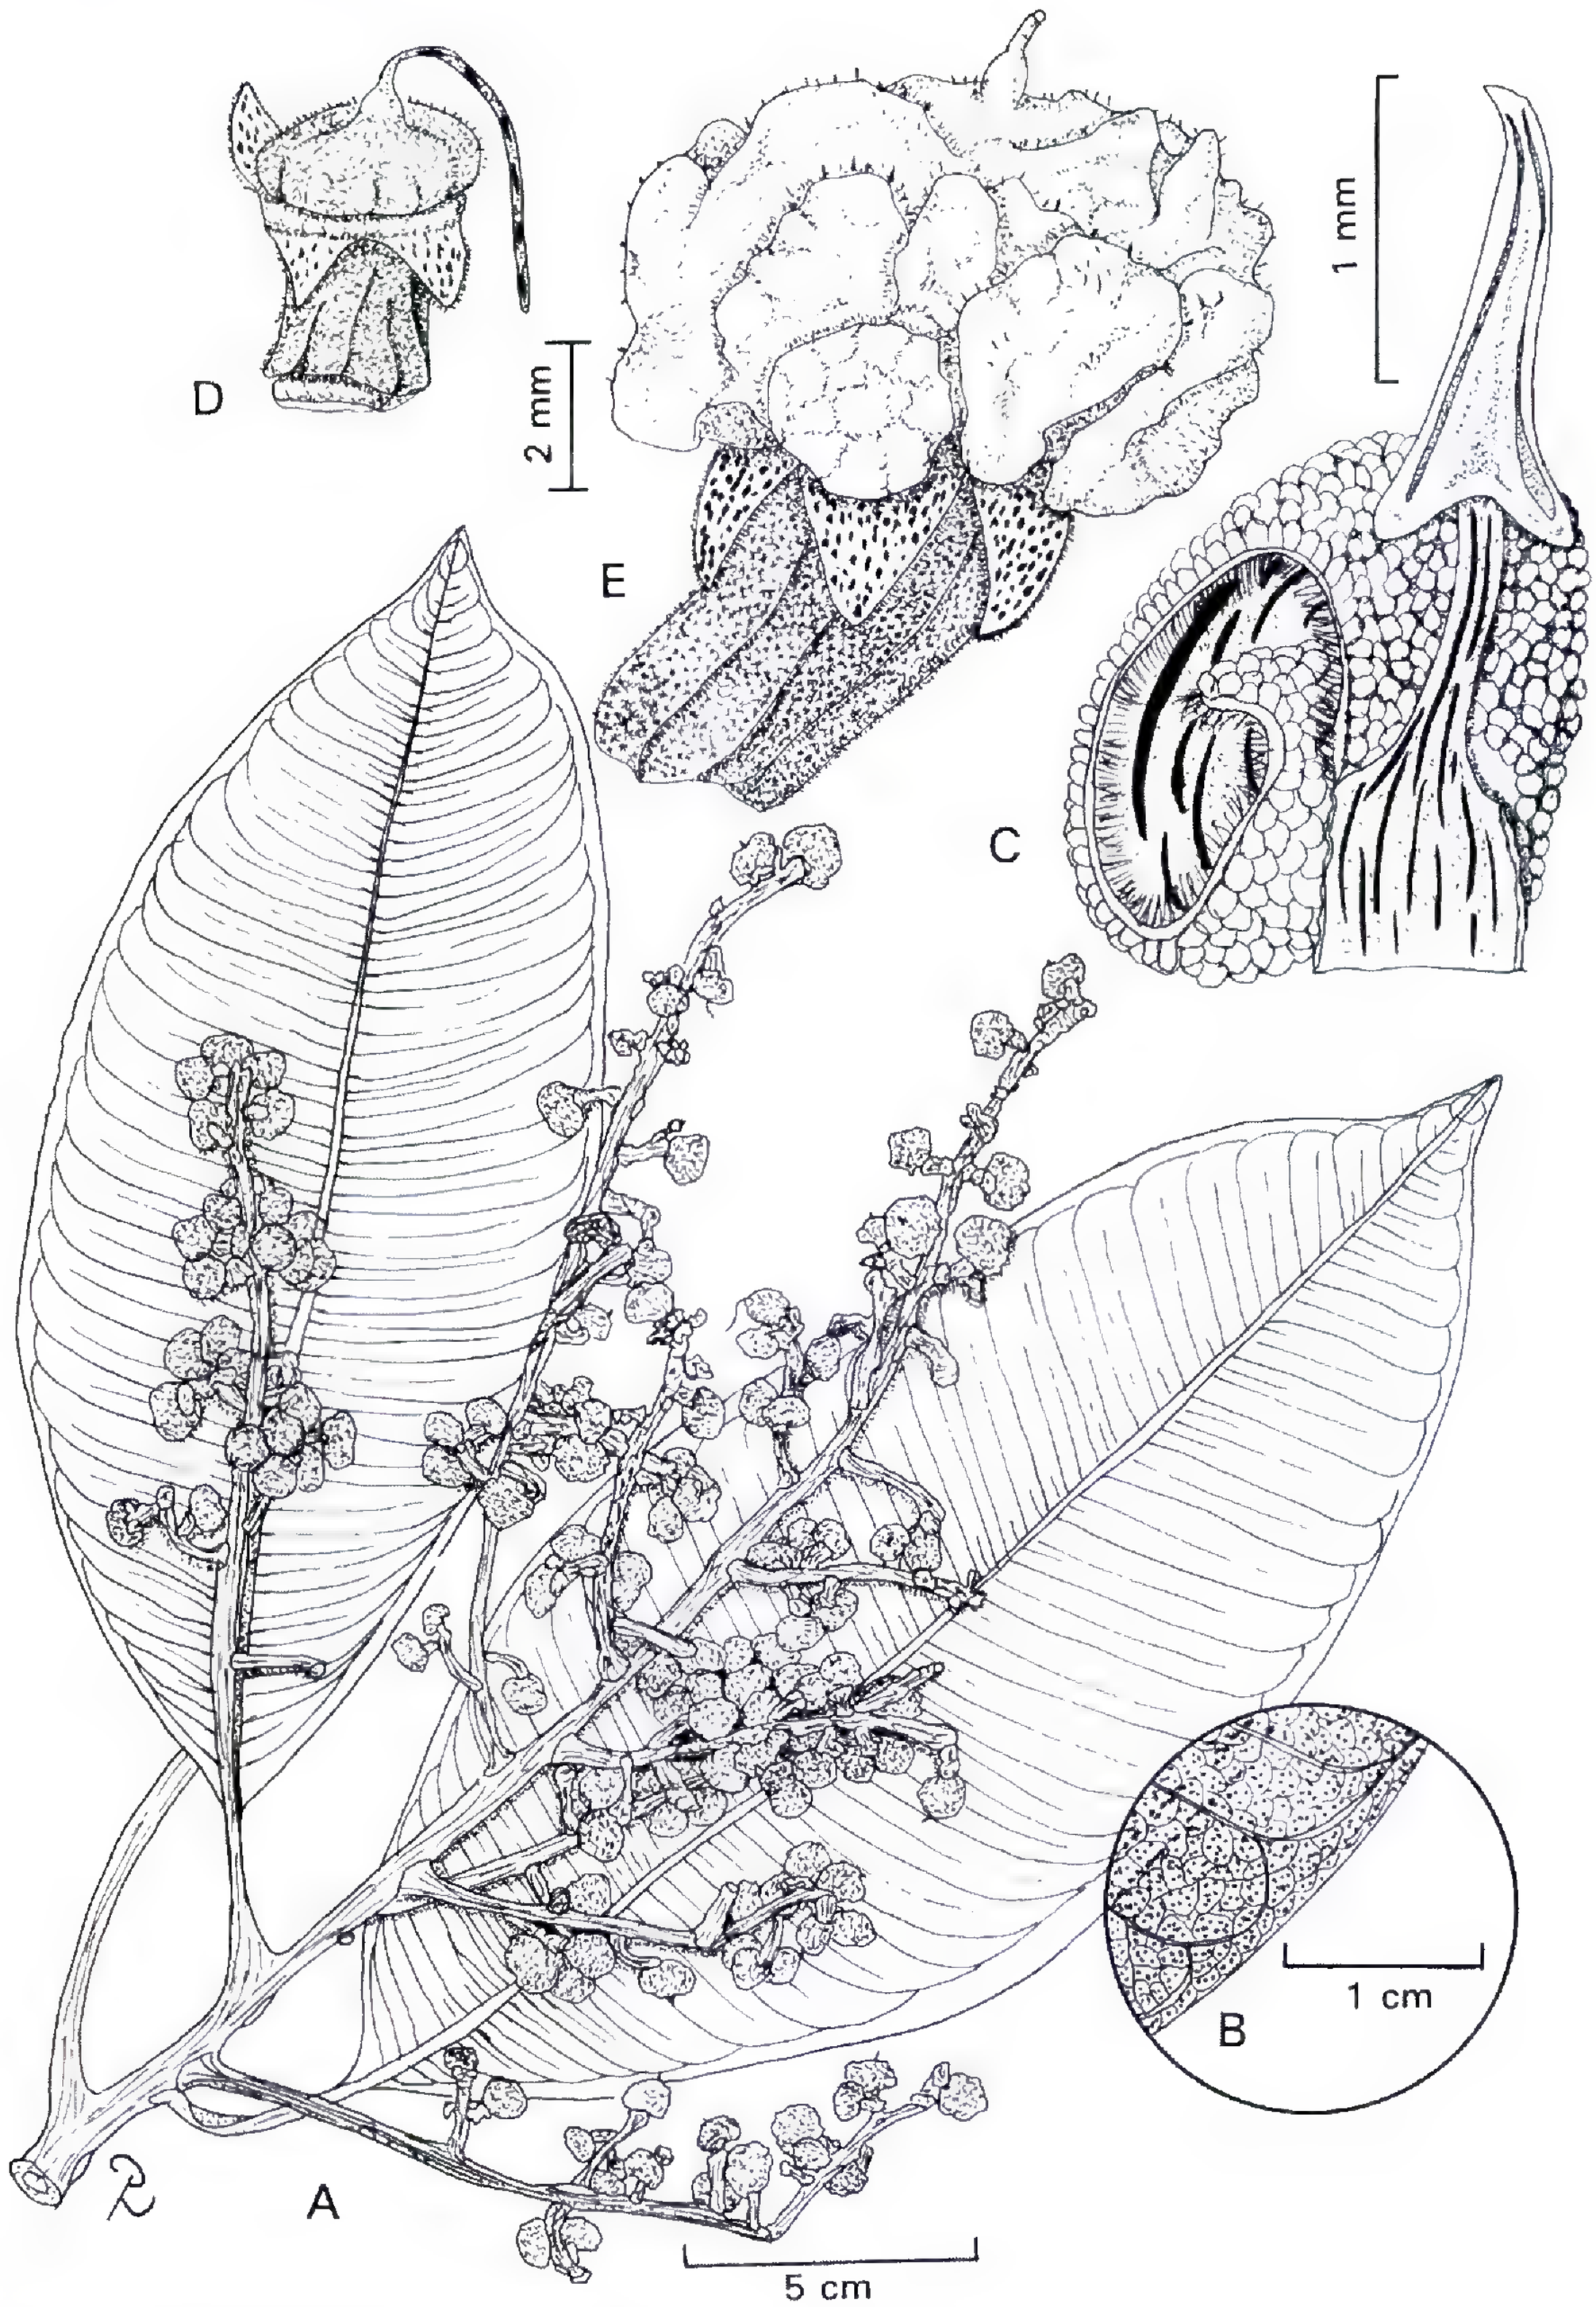

FIG. 2. *Parathesis pseudocrassiramea* Ricketson & Pipoly. **A.** Flowering branch. **B.** Detail of abaxial leaf surface. **C.** Detail of flower, showing corolla lobe with glandular papillae and stamen. **D.** Flower with immature fruit. **E.** Fruit. A–E drawn from isotype, *E. Alfaro 1431* (MO).

ceous, 5–5.2 mm long, the tube, 0.8–1 mm long, the lobes linear-lanceolate, 4.1–4.3 mm long, 1–1.2 mm wide, apically long acuminate, conspicuously and prominently punctate and punctate-lineate, densely tomentose near the base within, the margins entire; stamens 2.8–3 mm long, the filaments 1.8–2 mm long, the staminal tube 0.5–0.7 mm long, the apically free portion 1.2–1.4 mm long, conspicuously and prominently punctate and punctate-lineate, glabrous, the anthers yellow, 1.5–1.8 mm long, 0.6–0.8 mm wide, apically acuminate, apiculate, basally sagittate, the connective, conspicuously and prominently punctate and punctate-lineate; pistil 4.3–4.6 mm long, the ovary ovate, 0.9–1 mm long, conspicuously and prominently punctate and punctate-lineate, densely tomentose with appressed simple or stellate trichomes, the style 3.4–3.6 mm long, conspicuously and prominently punctate and punctate-lineate, glabrous, the ovules unknown. ***Fruits*** depressed globose, 4–5 mm long, 6–9 mm wide, conspicuously and prominently punctate and punctate-lineate, densely puberulent of finely appressed simple or stellate trichomes, inconspicuously costate.

Distribution.—Parathesis pseudocrassiramea is only known from the type collection in the Parque Nacional Chirripó, San José, Costa Rica, growing from 1300–1400 m elevation.

Ecology and conservation status.—Parathesis pseudocrassiramea occurs in premontane forests. Although it seems protected in the Chirripó National Park, it is only known from the type collection and should be considered threatened at this time.

Etymology.—The specific epithet comes from it close affinity to *Parathesis crassiramea.*

The type is in fruit with few partial remnant flowers and buds. The remaining buds appear to house insects, thus bud measurements are inaccurate. The fruits are unusual in the genus and appear as a "cauliflower" shape, however this may be strictly because they were "juicy" at the time of collecting and the "wrinkled" nature may be caused by the drying process.

Parathesis pseudocrassiramea is closely related to *P. crassiramea* because of the bullate leaves, terminal inflorescences, and the ovary densely puberulent with finely appressed simple or stellate trichomes. The leaf blades of *P. pseudocrassiramea* are larger, to 25 × 10.5 cm, and essentially glabrous below but with a few papillae or glandular granules at the very base, while in *P. crassiramea* they are inconspicuously to conspicuously bizonal below with the marginal zone glabrous and the costal zone sparsely to scattered fine appressed with whitish stellate trichomes. In fruit, *P. pseudocrassiramea* may also be confused with *P. cartagoana*; however, the vestiture of the lower leaf surface is inconspicuously or conspicuously bizonal and the marginal zone is strongly appressed with dense, canescent stellate or dendroid trichomes and the costal zone has a mixture of appressed, dense, canescent or ferrugineous to tomentose stel-

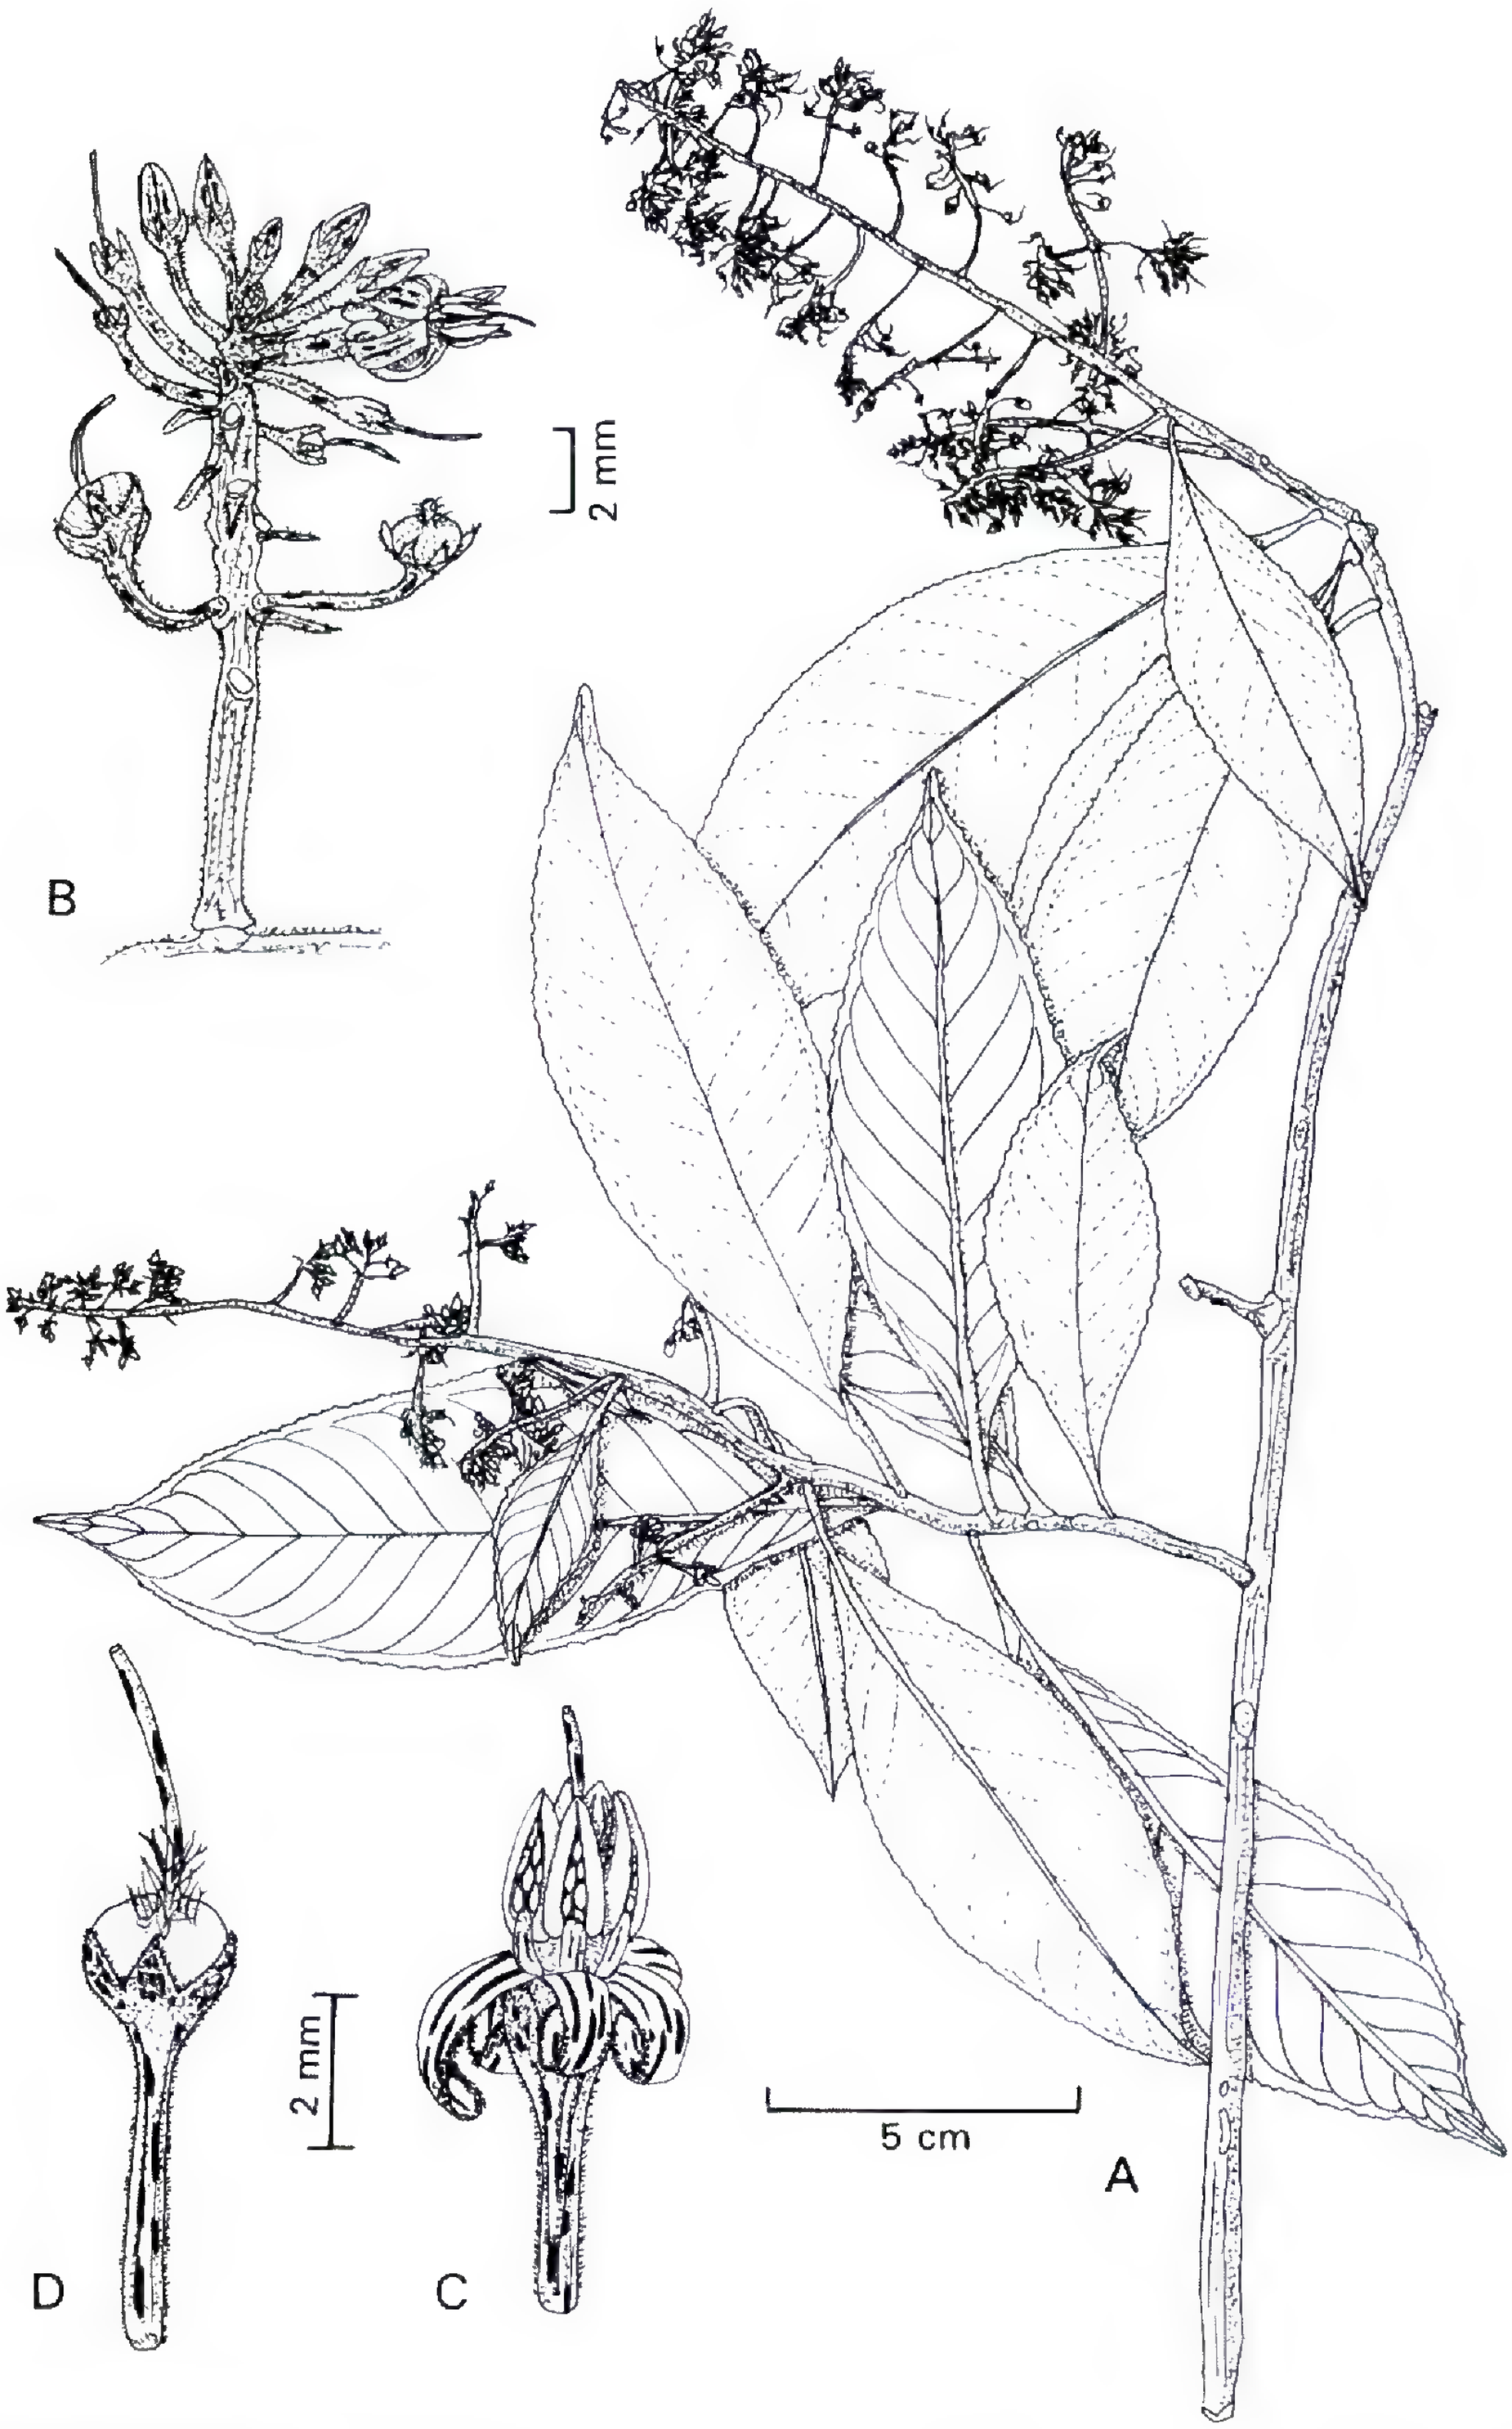

FIG. 3. *Parathesis rothschuhiana* Mez. **A.** Flowering branch. **B.** Detail of inflorescence. **C.** Flower. **D.** Fruit. A–D drawn from *J. Atwood & D. Neill 14* (MO).

late and/or dendroid trichomes with scattered erect reddish dendroid trichomes, which immediately separate the two taxa.

In addition to the aforementioned novelties, revision of the genus disclosed the necessity of neotypifying *Parathesis rothschuhiana* Mez.

Parathesis rothschuhiana Mez, Pflanzenr. IV. 236 (Heft 9):176. 1902. (**Fig. 3**). TYPE. NICARAGUA. MANAGUA: Grenze der Berg und savannenregion, 550 m, 9 Mar 1894 (fl., fr.), *E. Rothschuh 531* (HOLOTYPE: B destr. 1943, F neg.4875); NEOTYPE. NICARAGUA. NUEVA SEGOVIA: a la orilla del Río Achuapa al S del Cerro Mogotón, 1,500 m, 12 Jun 1975 (fl.), *J. Atwood & D. Neill 14* (NEOTYPE, here selected: MO; ISONEOTYPE: FTG).

Ardisia fusca Oerst. var. *glabrata* Oerst., Vidensk. Meddel. Dansk Naturhist. Føren Kjøbenhavn 1861:128. 1862. TYPE. NICARAGUA. JINOTECA: sylvis humidis monte Pantasmo, [13° 28' N, 85° 54' W], 3,000–4,000 leg [914–1,219 m], Jan 1848 (fl.), *A. Oersted 37A* (HOLOTYPE: C; ISOTYPE: LL).

The holotype of *Parathesis rothschuhiana* was destroyed at Berlin (B) in March 1943, thus necessitating the need to located an isotype. Unfortunately, the *E. Rothschuh* specimens were not widely distributed, the only other institutions known to house his material are Leiden (L) and the Smithsonian (US). Searches of these herbaria, as well as the National Herbarium of Nicaragua (HNMN), have failed to locate a duplicate specimen. In the absence of any original type material a neotype must be selected. The *J. Atwood & D. Neill 14* material is in good condition with mature flowers and young fruits. Unfortunately, a search by Alfredo Guijalva (HNMN) of Nicaraguan herbaria has failed to locate a duplicate of this specimen. Thus we hereby designate the *J. Atwood & D. Neill 14* sheet at MO as the neotype.

Oersted (1862) was the first to recognize the unique characters of this taxon, when he described *Ardisia fusca* Oerst. var. *glabrata* Oerst. However, Mez (1902) misunderstood the material and synonymized the variety under *Parathesis fusca* (Oerst.) Mez and failed to recognize the similarities between the type of *Ardisia fusca* Oerst. var. *glabrata* Oerst. with his new species *P. rothschuhiana* Mez. Lundell (1966) in his revision of the genus was the first to synonymize the taxon under *Parathesis rothschuhiana* but was unable to locate any type material.

ACKNOWLEDGMENTS

We wish to thank the Missouri Botanical Garden (MO), Gerrit Davidse (MO) and the *Flora Mesoamericana* Project for its support, to bring Ricketson and Pipoly together to work on the project. We gratefully acknowledge the loans from the herbaria that made this study possible, along with our collaborators who supplied us with much critical material. We also gratefully wish to thank Alfredo Guijalva (HNMN) for his diligent search for specimens in Nicaragua. Thanks are due to Roy Gereau (MO) for comments on the Latin diagnosis. Gerrit Davidse and Zachary Rogers (MO) generously gave of their time to provide thorough reviews of the manuscript.

Book Review

William T. Stearn. 2002. **The Genus *Epimedium* and Other Herbaceous Berberidaceae including the Genus *Podophyllum*.** (ISBN 0-88192-543-8, hdbk.) Timber Press, Inc., 133 S.W. Second Ave, Suite 450, Portland, OR 97204-3527. (Orders: www.timberpress.com, 503-227-2878, 1-800-327-5680, 503-227-3070 fax). $49.95, 354 pp, 27 color paintings, 75 color photos, 31 line drawings, 7 b/w photos, 7 3/8" × 9 5/8".

Though *Epimedium* species have been cultivated for centuries in Asia, it is only relatively recently that the taxonomy has been understood, indeed in great part to the author of this book. William Stearn, who is probably best known for his other books, *Botanical Latin* and *Dictionary of Plant Names for Gardeners*, provides in his posthumous publication a comprehensive monograph of *Epimedium* species and cultivated hybrids. Other herbaceous Berberidaceae genera are treated in this book as well, including *Achlys, Bongardia, Caulopyhllum, Diphylleia, Gymnospermium, Jeffersonia, Leontice, Ranzania*, and *Vancouveria*. A treatment of 14 species of *Podophyllum* is provided by Julian Shaw.

A historical introduction begins the book, in addition to a general description of the herbaceous genera in Berberidaceae and a key to these genera. The second chapter is filled with facts on touted medicinal properties, discovery and treatment of new species by 18th century botanists, and modern hybridization of species for cultivation. Interestingly, the genus was first described by Linneaus in 1753 when he described *Epimedium alpinum*, but it remained monotypic until 1821. Chapter three is a extensive description of morphologic characters, including rhizome, stem, foliage, flowers and fruits. Stearn elaborates on the importance of floral morphology with three extensive figures that include line drawings of the flowers and spurred petals of each species. Next, Stearn explains his classification system for *Epimedium*, which comprises two subgenera and four sections and his biogeographical hypotheses for present distributions of *Epimedium*. The taxonomic treatment of *Epimedium* in chapter seven is comprehensive, beginning appropriately with a key to species and following with descriptions of 54 species and 20 hybrids. Each species description includes eponymy, synonymy, diagnostic characteristics, illustration citations and geographic distribution. In addition, each species has an illustration and/or a color photograph to accompany the text. The rest of the book is dedicated to description of the other aformentioned herbaceous taxa. Descriptions of these taxa follow the same format as *Epimedium*.

Commonly called Barren-worts, *Epimedium* species are increasingly popular in North American landscapes and woodland gardens. Clearly, Stearn himself was interested in the horticulture of herbaceous Berberidaceae, since this book is littered with comments on the history of their cultivation. The comprehensive information provided here by Stearn and collaborators makes it a worthwhile read for a variety of audiences. The importance of this book to taxonomy notwithstanding, people interested in species of herbaceous Berberidaceae, the origins of *Epimedium* and other taxa, and the cultivation of hybrids should consider adding this book to their library.—*Amy Trauth Nare, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX, 76102-4060, U.S.A., amy_trauth@yahoo.com.*

ABSTRACT

Ardisia escallonoides, *Myrsine myricoides* and *Parathesis melanostricta* (Myrsinaceae), are lectotypified, based on Schiede and Deppe collections housed at HAL.

RESUMEN

Se lecotipifican *Ardisia escallonoides*, *Myrsine myricoides* y *Parathesis melanostricta* (Myrsinaceae), en base a colecciones de Schiede y Deppe guardados en el herbario HAL.

INTRODUCTION

C.J.W. Schiede and F. Deppe collected in central Mexico between 1828 and 1836, and sent those collections to D.F.L. von Schlechtendal in Berlin (now B). Schlechtendal with A. von Chamisso determined the material and published the results in a series of papers in *Linnaea*. However, in 1833 Schlechtendal moved from Berlin to become the Director of the Botanical Garden and professor of botany at Friedrichs-Universität (since 1933 Martin-Luther-Universität) in Halle, Germany. He transferred his private herbarium to Halle, which contained numerous duplicates of collections from B. After his death in 1866, his private herbarium was acquired by the university and merged with the university herbarium (now known as HAL). Given that the herbarium in Berlin was destroyed in 1943 during World War II, we cannot be sure whether Schlechtendal transferred the types for the new species of Myrsinaceae to HAL when he moved, or brought only duplicates. Therefore, the only choice we have is to lecotypify his names with the duplicates at HAL that bear notes handwritten by Schlechtendal. Lecotypifications are as follows:

Ardisia escallonioides Schltdl. & Cham., Linnaea 6:393. 1831. *Tinus escallonioides* (Schltdl. & Cham.) Kuntze, Revis. Gen. Pl. 2:974. 1891. TYPE: MEXICO. VERACRUZ: in sylvis Papantlae [Papantla], without elev., Dec 1828 (fl., fr.), *C. Schiede & F. Deppe 1226* (LECTOTYPE, here designated: HAL accession number 89724-A + B; ISOLECTOTYPES: K, MO (LL neg. 1971-39), W).

We here by designate the collection at HAL, accession number 89724 A+B as the lectotype.

Myrsine coriacea (Sw.) R. Br. ex Roem. & Schult. *Myrsine myricoides* Schltdl., Linnaea 8:525. 1834. *Rapanea myricoides* (Schltdl.) Lundell, Wrightia 3:109. 1964. TYPE. MEXICO. VERACRUZ: Jalapae [Jalapa], without elev., May 1829 (fr.), *C. Schiede 175* (LECTOTYPE, here designated: HAL accession number 89723-Bogen A/AB; ISOLECTOTYPES: HAL 89723-Bogen B/AB, MO).

Myrsine myricoides Schltdl. has been considered a synonym of *M. coriacea* (Sw.) R. Br. ex Roem. & Schult. for some time. In our previous publications Pipoly (1992a), Ricketson & Pipoly (1997,1999) we erroneously attributed the type to *H. Galeotti 521, 522 and 526* based on Mez's (1902) list of species. Lundell (1964) also failed to designate a lectotype when he placed this species in the now synonymized genus *Rapanea*, see: C. Chen and Pipoly (1996), Pipoly (1991, 1992a, 1992b, 1996) and Pipoly and C. Chen (1995). It is now clear that Schlechtendal based his new species solely on the *C. Schiede 175* collection. As noted above, HAL has two specimens of this collection, we here by designate the specimen with the hand written label (in Schiede's hand) that states, "175, Myrica jalapensis form., Jalapae, Maj. 29." This specimen also includes a label from Schlechtendal "*Myrsine myricoides* n. sp." and a determination slip from Carl Mez, 1901 determined as *Rapanea ferruginea* [(Ruíz & Pav.)] Mez. The HAL isolectotype does not have a locality label with only the Schlechtendal's hand written label stating "175, *Myrsine myricoides*" without the "n. sp." addition. This lends further evidence for selecting the specimen with the hand written locality label.

Parathesis melanostricta (Schltdl.) Hemsl., Biol. Centr.-Amer., Bot. 2:291. 1881. *Ardisia melanostricta* Schltdl., Linnaea 8:526. 1834. TYPE. MEXICO. VERACRUZ: In sylvis inter San Salvador et Jalapam, Jun 1829 (fl.), *C. Schiede 178* (LECTOTYPE: HAL; ISOLECTOTYPES: G (F neg. no. 26685), GH, MO, NY (LL neg. no. 1217), W).

We here by designate the HAL collection, accession number 95759, as the lectotype.

ACKNOWLEDGMENTS

We are most grateful to Uwe Braun of Martin-Luther-Universität, Curator of the HAL herbarium, for his advice and photocopying of the Schlechtendal specimens. We are also grateful to Gerrit Davidse and the Flora Mesoamericana project (MO) and Fairchild Tropical Garden for support of our joint work. Both Braun and Davidse generously gave of their time to provide thorough reviews of the manuscript.

BOOK NOTICES

DAVID YETMAN. 2002. **The Guarijíos of the Sierra Madre: hidden People of Northwestern Mexico.** (ISBN 0-8263-2234-4). University of New Mexico Press, 1720 Lomas Boulevard NE, Albuquerque, NM 87131-1591, U.S.A. (Orders: 1-800-249-7737; 1-505-277-9270 fax.) $49.95, 270 pp., numerous b/w photos, 1 map, 8 1/2" × 11 1/4".

The Guarijíos are a native tribe of Mexico's remote Sonora desert, a rugged land of mountains, canyons, plains, and the all-important river. It is a land perhaps best known to botanists through Howard S. Gentry's *Rio Mayo Plants* (1942) and *Gentry's Rio Mayo Plants*, by P.S. Martin, Yetman, et al. (1998.) Yetman journeyed there again to study the plants and the ways that the native use the plants. Actually, by showing an interest in the plants, he became acquainted with the people and their lives so that his book is more of an anthropological study than a botanical one. Nevertheless plants figure predominantly, though it is in no way an attempt to update the earlier works. Rather, Yetman concentrates on the usage (food, medicine, lumber, etc.) with an introductory "plant primer" of nine unusual plants. He culminates his findings with a list of plants, the "ethnoflora" of the Guarijíos.—*Joann Karges, Botanical Research Institute of Texas, Fort Worth, TX, U.S.A.*

DAVID YETMAN and THOMAS R. VAN DEVENDER. 2002. **Mayo Ethnobotany: Land, History, and Traditional Knowledge in Northwest Mexico.** (ISBN 0-520-22721-2, hbk.). University of California Press, Berkeley, CA. U.S.A. (Orders: California Princeton Fulfillment Services, 609-883-1759; Fax 609-883-7413) $48.00 hbk. 359 pp., numerous black and white photographs.

In more than fifty trips of four to ten days between the early 1990s and 2000 the authors visited the Mayos of Sonora and Sinaloa, studying their land, their customs, and especially their use of plants. These are people who for the most part live off the land and so incorporate most of the plants in one way or another in their daily living. After a comprehensive explanation of the of the geography and topography of the land and the ethnography of the Mayos, the authors describe eight plants that are most important to the Mayos, plants that "make the Mayos Mayos." Following is a list of the plants of the areas, arranged by family, and providing the Mayo and Spanish names as well as the binomial. The authors describe the growing characteristics of each plant and cite its uses—some vitally important (construction, food, medicine) and some trivial (such as kindling or a children's seed spitting game).

With this work, Yetman and Van Devender have contributed another in their growing body of publications that lead to an understanding of the Mayos and their culture as it relates to plants—*Joann Karges, Botanical Research Institute of Texas, Fort Worth, TX, U.S.A.*

A SYNOPSIS AND NOMENCLATOR OF THE GENUS *PARATHESIS* (MYRSINACEAE)

ABSTRACT

A new infrageneric classification for the genus *Parathesis* is proposed. The genus is divided into two subgenera, *Parathesis* subg. *Laterales* Ricketson & Pipoly, and subg. *Parathesis*. *Parathesis* subgenus *Laterales* is further divided into sections *Calophyllae* Ricketson & Pipoly, and *Laterales* Ricketson & Pipoly. *Parathesis* subg. *Parathesis* is also further divided into sections *Cubanae* Ricketson & Pipoly, *Parathesis*, and *Versatiles* Ricketson & Pipoly. All 95 species are listed in their respective sections.

RESUMEN

Se propone una nueva clasificación infragenérica para el género *Parathesis*. Se divide el género en dos subgéneros, *Parathesis* subg. *Laterales* Ricketson & Pipoly, y subg. *Parathesis*. Se divide el *Parathesis* subgénero *Laterales* en secciones: *Laterales* Ricketson & Pipoly, y *Calophyllae* Rickeston & Pipoly. Se divide *Parathesis* subg. *Parathesis* en secciones, *Cubanae* Ricketson & Pipoly, *Parathesis* y *Versatiles* Ricketson & Pipoly. Se enumeran todas las 95 especies del género en sus secciones respectivas.

INTRODUCTION

The genus *Parathesis* (A.DC.) Hook. f. was first described as a section of *Ardisia* Sw. by Alphonse de Candolle (1844) and included five species: *Ardisia cubana* A. DC. (*P. cubana* (A. DC.) Molinet & M. Gómez), *A. crenulata* Vent. (*P. crenulata* (Vent.) Hook. f. ex Hemsl.), *A. serrulata* Sw. (*P. serrulata* (Sw.) Mez), *A. lateriflora* Sw. (= *Stylogyne lateriflora* (Sw.) Mez) and *A. lepidota* Kunth. (= *Geissanthus lepidotus* (Kunth) Mez). *Parathesis* was elevated to the generic level by J.D. Hooker (1876).

In the first in-depth study of the genus, Carl Mez (1902) listed 20 species of *Parathesis*, including seven new species. However, it wasn't until C.L. Lundell (1966) published his monograph on the genus *Parathesis* that a usable classification was developed. Lundell listed 71 species divided into two "Sections" and 23 "Series". Admittedly Lundell stated (1966: p. 8) that his infrageneric classification was "designed to expedite the use of the general key," and therefore comprises a numerical listing rather than a formal classification.

Since Lundell's monograph was published, numerous species have been described, usually with no refernece to Lundell's classification system. Currently, we recognize approximately 150 taxa of *Parathesis*, 95 at the rank of species. Although Lundell's system is helpful, it is far too large and cumbersome to

be useful. In preparation for our treatment of the genus *Parathesis* for *Flora Mesoamericana*, a new infrageneric classification system was needed, which is formalized herewith. The species listed reflect our current understanding of the genus. Complete synonymies will appear in the *Flora Mesoamericana* and *Flora Neotropica*.

TAXONOMIC TREATMENT

Parathesis (A. DC.) Hook. f. in Benth. & Hook. f., Gen. pl. 2:645. 1876. *Ardisia* sect. *Parathesis* A. DC., Prodr. 8:120. 1844. TYPE: *Parathesis serrulata* (Sw.) Mez.

Terrestrial polyaxial shrubs and trees. Young branchlets frequently ferrugineous-tomentose with stellate or dendroid trichomes, often glabrescent. Leaves monomorphic, alternate, the blades usually pubescent on the lower surface, the trichomes stellate or dendroid, often appressed and bizonal, often early glabrescent, or glabrous, usually paler beneath; costa and primary lateral veins usually elevated beneath, smooth or impressed above; margins entire, crenulate, dentate or serrate; petioles marginate or canaliculate. Inflorescences terminal or lateral, paniculate and pyramidal, the branches umbellate, corymbose or subcorymbose-racemose; pedicels accrescent. Flowers bisexual, (4-or)-5 (or-6)-merous; calyx connate at the base, open in bud, usually glandular tomentulose and papillose; corolla rotate, valvate, usually narrowly lanceolate, white to pink, usually tomentulose outside, glandular papillose-tomentose inside at least along margins and apically, connate basally to form a tube; stamens included, inserted near the base of corolla tube, the filaments well developed, slender to stout, usually connate basally to form a tube, the bright yellow anthers erect or versatile, usually dorsifixed above base, dehiscent by introrse slits or apical pores, sagittate, lanceolate to ovate, acute, mucronate, apiculate or obtuse at the apex, dorsally punctate or epunctate; pistil obturbinate, the ovary ovoid or subglobose, the style long and slender, the stigma punctiform, ovules few to numerous, usually uniseriate, sometimes biseriate or rarely pluriseriate on the placenta. Fruits drupaceous, 1-seeded, usually depressed-globose, the endocarp crustaceous, the embryo cylindric, transverse.

A genus of ca. 95 species ranging from northern Mexico to Panama, the Carribean and throughout the Andes from Venezuela to Bolivia. Members of the genus occur from coastal mangroves to elfin forest formations at high elevations. The genus is diagnosed by the unique glandular papillae of the calyx and corolla lobes, and the bright yellow anthers.

KEY TO THE SUBGENERA AND SECTIONS OF *PARATHESIS*

1. Inflorescences lateral, or terminal and lateral _____ **Subg. Laterales**
   2. Tomentum of branchlets and the undersurface of the leaves fine, mostly stellate and usually closely appressed, sometimes sub-appressed and rather loose, often glabrescent _____ **Sect. Laterales**

2. Tomentum of branchlets and undersurface of the leaves usually coarse and conspicuous and of distinct reddish trichomes, the trichomes dendroid and sessile or stipitate, or the trichomes stellate with erect and spreading rays, the stellate trichomes either sessile, subsessile, or stipitate _____ **Sect. Calophyllae**

1. Inflorescences terminal, pyramidal-paniculate _____ **Subg. Parathesis**

3. Anthers versatile, or tardily versatile, with longitudinal slits, dorsifixed at or about the middle; filaments usually longer than the anthers _____ **Sect. Versatiles**

3. Anthers erect, with longitudinal slits and/or subterminal pores, usually dorsifixed near the base, never versatile; filaments shorter than the anthers, often one-half as long.

4. Tomentum of branchlets and abaxial leaf surface fine, mostly sessile or subsessile stellate and usually closely appressed, sometimes sub-appressed and rather loose, often glabrescent _____ **Sect. Cubanae**

4. Tomentum of branchlets and undersurface of the leaves usually coarse and conspicuous and of distinct reddish trichomes, the trichomes dendroid, sessile or stipitate, or the trichomes sessile, subsessile or stipitate stellate with erect and spreading rays, usually persistent. _____ **Sect. Parathesis**

Parathesis (A. DC.) Hook. f. in Benth. & Hook. f. subg. **Laterales** Ricketson & Pipoly, subg. nov. TYPE (here designated): *Parathesis adenanthera* (Miq.) Hook. f. ex Mez.

Hoc subgenus a subgenere Parathese inflorescentiis lateralibus (axillaribus) vel terminalibus et lateralibus perfacile separabilis.

Inflorescences lateral (axillary), or terminal and lateral (axillary).

Parathesis subg. *Laterales* as circumscribed here consists of two sections (sect. *Calophyllae* and sect. *Laterales*) and includes 42 species.

Parathesis subg. **Laterales** Ricketson & Pipoly sect. **Calophyllae** Ricketson & Pipoly, sect. nov. TYPE: *Parathesis calophylla* Lundell.

Sectio haec a sectione Lateralibus tomento grosso conspicuo arque persistente statim distat.

Inflorescences axillary, or terminal and axillary; tomentum of branchlets and undersurface of the leaves usually coarse and conspicuous and of distinct reddish trichomes, the trichomes dendroid and sessile or stipitate, or the trichomes stellate with erect and spreading rays, the stellate trichomes either sessile, subsessile, or stipitate.

Parathesis subg. *Lateralis* sect. *Calophyllae* contains 9 species:

Parathesis calophylla Donn. Sm.
P. oerstediana Mez
P. pipolyana Ricketson
P. pleurobotryosa Donn. Sm.
P. pseudocalophylla Ricketson & Pipoly
P. reflexa Brandegee
P. schultesii Lundell
P. travisae Lundell
P. vestita Lundell

Parathesis subg. **Laterales** Ricketson & Pipoly sect. **Laterales** Ricketson & Pipoly, sect. nov. TYPE: *Parathesis adenanthera* (Miq.) Hook. f. ex Mez.

Sectio haec sectionem Laterali inflorescentiis lateralibus vel lateralibus et terminalibus, tomentio subtiliter adpresso vel subadpresso atque plerumque glabrescentes statim distat.

Inflorescences lateral, or terminal and lateral; tomentum of branchlets and undersurface of leaves fine, mostly stellate and usually closely appressed, sometimes sub-appressed and rather loose, often glabrescent.

Parathesis subg. *Laterales* sect. *Laterales* contains 33 species:

Parathesis adenanthera (Miq.) Hook. f. ex Mez
P. angustifolia Lundell
P. aurantiaca Lundell
P. calzadae Lundell
P. candolleana Mez
P. cintalapana Lundell
P. conzattii (S.F. Blake) Lundell
P. cuspidata Lundell
P. glaberrima Lundell
P. glabra Donn. Sm.
P. gracilis Lundell
P. leptopa Lundell
P. macrantha Lundell
P. macronema Bullock
P. melanosticta (Schltdl.) Hemsl.
P. minutiflora Lundell
P. montana Lundell
P. moritziana Mez
P. multiflora Lundell
P. psychotrioides Lundell
P. rekoi Standl.
P. seibertii Lundell
P. skutchii Lundell
P. subulata Lundell
P. tartarea Lundell
P. tenuis Standl.
P. tomentosa Lundell
P. venezuelana Mez
P. villosa Lundell
P. vulgata Lundell
P. wendtii Lundell
P. rekoi Standl.
P. seibertii Lundell

Parathesis (A. DC.) Hook. f. subg. **Parathesis**.

Inflorescences terminal, pyramidal-paniculate

Parathesis subg. *Parathesis* as circumscribed here consists of three sections (sect. *Cubanae*, sect. *Parathesis* and sect. *Versatiles*) and includes 53 species.

Parathesis subg. **Parathesis** sect. **Cubanae** Ricketson & Pipoly, sect. nov. TYPE: *Parathesis cubana* (A. DC.) Molinet & M. Gómez.

Sectio haec quoad antheras erectas dorsifixas longitudinaliter vel subapicaliter dehiscentes necnon filamenta antheris breviora, sect. Parathesi valde affnis, sed ab ea foliis ramulisque subtiliter et adpresse- (nec grosse et erecte) tomentosis perclare distinguitur.

Inflorescence terminal, pyramidal-paniculate; anthers erect, with longitudinal slits and/or subterminal pores, usually dorsifixed near base, never versatile; filaments shorter than the anthers, usually one-half as long; tomentum of branchlets and undersurface of leaves fine, mostly stellate and usually closely appressed, sometimes subappressed and rather loose, often glabrescent.

Parathesis subg. *Parathesis* sect. *Cubanae* contains 26 species:

Parathesis agostiniana Lundell
P. bracteolata Lundell
P. breedlovei Lundell
P. crassiramea Lundell
P. crenulata (Vent.) Hook. f. ex Hemsl.
P. cubana (A. DC.) Molinet & M. Gómez
P. donnellsmithii Mez
P. emarginata Mez

P. ferruginea Lundell
P. lanceolata Brandegee
P. laxa Lundell
P. lenticellata Lundell
P. mexicana Lundell
P. microcalyx Donn. Sm.
P. obtusa Lundell
P. parvissima Lundell
P. perpunctata Lundell
P. pseudocrassiramea Ricketson & Pipoly
P. reticulata Lundell
P. rosea Lundell
P. rothschuhiana Mez
P. sinuata (Lundell) Ricketson & Pipoly
P. subcoriacea Lundell
P. tetramera Bullock
P. williamsii Lundell
P. zuliana Lundell

Parathesis subg. **Parathesis** sect. **Parathesis**

Inflorescences terminal, pyramidal-paniculate; anthers erect, with longitudinal slits and/or subterminal pores, usually dorsifixed near base, never versatile; filaments shorter than anthers, usually one-half as long; tomentum of branchlets and undersurface of leaves usually coarse and conspicuous and of distinct reddish trichomes, the trichomes dendroid and sessile or stipitate, or the trichomes stellate with erect and spreading rays, the stellate trichomes either sessile, subsessile, or stipitate.

Parathesis subg. *Parathesis* sect. *Parathesis* contains 15 species:

Parathesis acostensis J.F. Morales
P. aeruginosa Standl.
P. amazonica Mez
P. chiapensis Fernald
P. columnaris Lundell
P. eggersiana Mez
P. fusca (Oerst.) Mez
P. kochii Lundell
P. neei Lundell
P. prionophylla Standl.
P. rufa Lundell
P. serrulata (Sw.) Mez
P. sessilifolia Donn. Sm.
P. tenorioi Lundell
P. villalobosii Lundell

Parathesis subg. **Parathesis** sect. **Versatiles** Ricketson & Pipoly, sect. nov. TYPE: *Parathesis trichogyne* Hemsl.

Sectio haec inter alias antheris versatilis longitudinaliter deshiscentibus et dorsifixis, filamentis antheris longioribus statim diagnoscenda.

Inflorescences terminal, pyramidal-paniculate; anthers versatile, or tardily versatile, with longitudinal slits, dorsifixed at or about the middle; filaments usually longer than the anther.

Parathesis subg. *Parathesis* sect. *Versatiles* contains 12 species:

Parathesis acuminata Lundell
P. amplifolia Lundell
P. cartagoana Lundell
P. costaricensis Ricketson
P. croatii Lundell
P. glendae Ricketson
P. longipedicellata Ricketson
P. palaciosii Pipoly
P. panamensis Lundell
P. papillosa Lundell
P. pyramidalis Lundell
P. trichogyne Hemsl.

EXCLUDED TAXA

Parathesis acutissima Cuatrec. = *Hymenandra acutissima* (Cuatrec.) Pipoly & Ricketson
Parathesis micranthera Donn. Sm. = *Gentlea micranthera* (Donn. Sm.) Lundell
Parathesis viridis Lundell = *Stylogyne viridis* (Lundell) Ricketson & Pipoly

ACKNOWLEDGMENTS

We thank the Missouri Botanical Garden and the Flora Mesoamericana Project for its support to bring Ricketson and Pipoly together to work on the project. We gratefully acknowledge the loans from many herbaria that made the study possible, along with our collaborators who supplied us with much critical material. Gerrit Davidse and Roy Gereau generously gave of their time to provide thorough reviews of the manuscript.

ABSTRACT

Preparation of a taxonomic treatment of the Myrsinaceae for the *Flora Mesoamericana* project resulted in the discovery of a new species, *Stylogyne pucuroensis* Ricketson & Pipoly, which is described and illustrated. Its closest relationship is with *S. ardisioides* A. DC. *Stylogyne glomeruliflora* is removed from the project area.

RESUMEN

Al preparar un tratamiento taxonómico de la familia Myrsinaceae para Flora Mesoamericana, se descubrió una especie nueva para la ciencia, *Stylogyne pucuroensis* Ricketson & Pipoly. Se describe, se ilustra y se discute el parentezco de la nueva especie. Se elimina la especie *Stylogyne glomeruliflora* como registro para Mesoamerica como resultado del estudio.

Stylogyne pucuroensis Ricketson & Pipoly, sp. nov. (**Fig. 1**). TYPE. PANAMA. DARIÉN: Parque Nacional del Darién, ridge between N & S branches of Río Pucuro, in forest N of old village of Tacarcuna, ca. 18 km E of Pucuro, 077° 16' W, 08° 05' N, 600–800 m, 24 Oct 1987 (fr.), *B. Hammel, G. de Nevers, H. Cuadros & H. Herrera 16469* (HOLOTYPE: MO; ISOTYPES: FTG, LL, PMA).

Quoad inflorescentias laterales petiolos aequantes necnon flores 5-partitos *S. ardisioideo* valde arcte affinis, sed ab ea laminis ellipticis (non oblongis), petiolis marginatis (non canaliculatis) sepalis ovatis vel oblongis (non subdeltatis vel deltatis) 1.3–1.5 (nec 1.6–2.0) mm longis atro- (nec pellucido-) punctatis, denique fructu stylo persistente (non caduco) perfacile recognoscitur.

Shrubs to 3.5 m tall. ***Branchlets*** slender, terete, 1–3 mm in diam., glabrous. ***Leaves:*** with blades membranous, elliptic, 8.8–14.6 cm long, 2.8–5.6 cm wide, apically acuminate, with an acumen 1–1.6 cm long, basally acute, decurrent on the petiole, conspicuously and prominently punctate and punctate-lineate, glabrous, the midrib impressed above, prominently raised below, the secondary veins 37–47 pairs, inconspicuous above and below, the margins entire, flat; petioles slender, marginate, 0.5–1 cm long, glabrous. ***Inflorescences*** lateral, appearing paniculate, 3–5-racemose branches from a common fascicle, 0.5–1 cm long, 1–1.5 cm wide, shorter than the leaves, the rachis glabrous, the branches 3–7-flowered racemes; peduncles nearly obsolete, glabrous; inflorescence bracts unknown; floral bracts persistent, chartaceous, ovate, 0.5–0.6 mm long, 0.5–0.8 mm wide, apically acute, prominently punctate and punctate-lineate, glabrous, the veins inconspicuous, the margins entire; pedicels slender, terete, 2.3–3.2 mm long,

FIG. 1. *Stylogyne pucuroensis* Ricketson & Pipoly. **A.** Flowering branch. **B.** Fruiting inflorescence. Drawn from holotype, *B. Hammel et al. 16469* (MO).

prominently punctate and punctate-lineate, glabrous. ***Flowers*** 5-merous; calyx membranous, the sepals ovate to oblong, 1.3–1.5 mm long, 0.7–0.9 mm wide, apically acute, prominently punctate and punctate-lineate, glabrous, the margins entire; corolla, stamens and pistil unknown. ***Fruits*** red, globose, 4.5–5.3 mm in diam., conspicuously and prominently punctate and punctate-lineate, glabrous, conspicuously costate, the style base persistent.

Distribution.—Known only from the type collection in the Parque Nacional del Darién, adjacent to the lower slopes of Cerro Tacarcuna, in Darién, Panama, growing between 600–800 m elevation.

Ecology and conservation status.—*Stylogyne pucuroensis* occurs in premontane pluvial forest. Because it occurs in a remote area of the Darién near the Panama-Colombia border and within the National park, this species should not be considered threatened at this time.

Etymology.—The specific epithet comes from its locality, near the Río Pucuro.

Because of its lateral inflorescences equal to the petioles and 5-merous flowers, *Stylogyne pucuroensis* is most closely related to *S. ardisioides*. However, *S. pucuroensis* has elliptic (not oblong) leaf blades, marginate (not canaliculate) petioles, ovate to oblong (not subdeltate to deltate) sepals 1.3–1.5 (not 1.6–2) mm long with black (not pellucid) punctations. Finally in *S. pucuroensis* the persistent (not caducous) style on the fruit permit easy recognition.

In our previous paper (Ricketson & Pipoly 1997) this collection was confused with *Stylogyne glomeruliflora* Cuatrec., a species from the Chocó Floristic Province. However, further studies of the genus *Stylogyne* have shown that *S. glomeruliflora* is a member of a small group of taxa with 4-merous flowers, while *S. pucuroensis* has a 5-merous flower. Although the small lateral inflorescences are similar, a number of taxa possess this character, including *S. darienensis*, which has much longer, racemose branches. *Stylogyne glomeruliflora* should not be considered a member of either the Panamanian or Mesoamerican floras. We therefore provide a revised key to the species of *Stylogyne* in Mesoamerica.

KEY TO MESOAMERICAN SPECIES OF *STYLOGYNE*

1. Leaf blades bullate, pubescent, the margins crenate _____ **Stylogyne hayesii** Mez
1. Leaf blades smooth, glabrous, the margins entire.
   2. Inflorescences lateral, sessile or subsessile corymbose or racemose, 3–7-racemes from a common fascicle.
      3. Inflorescences elongated racemes or corymbs, 2–4.5 cm long; pedicels 3–3.5 mm; anthers strictly longitudinally dehiscent; fruits 5.5–6.5 mm in diam. _____ **Stylogyne darienensis** Lundell
      3. Inflorescences short racemes, 0.5–1 cm long; pedicels 0.5–2 mm; anthers dehiscent by pores opening into longitudinal slits; fruits 4–5 mm in diam. _____ **Stylogyne pucuroensis** Ricketson & Pipoly

2. Inflorescences terminal and/or lateral, paniculate _____ **Stylogyne turbacensis** (Kunth) Mez

4. Leaf blades obovate to oblanceolate, subcoriaceous, the punctations conspicuous above; inflorescences pyramidal-paniculate, mostly terminal, or occasionally terminal with few reduced lateral inflorescences _____ **Stylogyne turbacensis** subsp. **turbacensis**

4. Leaf blades elliptic to oblong, coriaceous, the punctations inconspicuous from above; inflorescences columnar-paniculate, mostly lateral or rarely lateral and terminal or pseudoterminal _____ **Stylogyne turbacensis** subsp. **laevis** (Oerst.) Ricketson & Pipoly

ACKNOWLEDGMENTS

We are grateful to Tom Wendt (TEX-LL) for loaning specimens, to the Missouri Botanical Garden (MO), to Gerrit Davidse (MO) as well as the Flora Mesoamericana Project, and finally Fairchild Tropical Garden (FTG) for their support of this inter-institutional research effort. Many thanks are due to Roy Gereau (MO) for reviewing the Latin diagnosis. Gerrit Davidse and James Solomon (MO) generously gave of their time to provide thorough reviews of the manuscript. The drawing was prepared by Jon Ricketson.

PTEROCERAS MONSOONIAE (ORCHIDACEAE), A NEW SPECIES FROM INDIA

N. Sasidharan and P. Sujanapal

Kerala Forest Research Institute
Peechi 680 653
Kerala, INDIA

ABSTRACT

A new species of the South East Asian Genus *Pteroceras* Hassk. is described, illustrated and compared to its closest relative *Pteroceras johorense*.

RESUMEN

Se describe una nueva especie del género *Pteroceras* Hassk. del sureste de Ásia, se ilustra y se compara con su pariente más próximo *Pteroceras johorense*.

INTRODUCTION

Pteroceras Hassk. is reported to have 19 species, mostly inhabited in the warm humid regions of Southeast Asia, and is best represented in Borneo with 10 species (Pedersen 1993). From Peninsular India, only one species, *Pteroceras leopardinum* (Parish & Reichb. f.) Seidenf. & Smitin., is reported. During our recent explorations in the Parambikulam Wildlife Sanctuary of Kerala interesting specimens of *Pteroceras* were collected. The specimens were found to differ from the South Indian species. Following the monograph of the genus (Pedersen 1993) the specimens show similarities with the little known *Pteroceras johorense* (Holttum) Holttum that seems to be endemic to Johor in Peninsular Malesia. However, they differ in the leaf form and size; texture, form and size of the peduncle, size of the bracts and floral parts; structure of labellum and pollinia (Table 1). Pedersen (1993) recognized four main types of inflorescences in the genus. Our species agrees with *Pteroceras asperatum* (Schltr.) P.F. Hunt, *P. hirsutum* (Hook. f.) Holttum, *P. johorense* (Holttum) Holttum, *P. muriculatum* (Reichb. f.) P.F. Hunt, *P. philippinense* (Ames) Garay and *P. spathibrachiatum* (J.J. Smith) Garay by having a muricate or prickly (sub)terete rachis without any keel or wings. Drawings of our material were sent to Pedersen who supported our view that it should be described and illustrated as a new species.

Pteroceras monsooniae Sasidharan & Sujanapal, sp. nov. (**Fig. 1**). TYPE: INDIA. KERALA. PALAKKAD DISTRICT: Parambikulam Wildlife Sanctuary, 10°32'226" N, 76°86'552" E, 1180m, 28 May 2000, *P Sujanapal KFRI 30407* (HOLOTYPE: KFRI; ISOTYPES: BRIT, CALI, MH, TBGT)

Pterocerati johorensi similis in rhachide aculeata tereti et perianthio oblong-ovato acuto vel rotundato, sed folii apice latus facto bilobato, pedunculo crasso brevi prominente aculeato, floribus

TABLE 1. Comparison of *Pteroceras monsooniae* with *P. johorense* (Holttum) Holttum.

Character	Pteroceras johorense[1]	Pteroceras monsooniae
Leaves	ca. 5 on a flowering shoot linear-lanceolate, 5–8 × 1–1.5 cm, apex narrowed, obtuse or unequally bilobed, lobes very small	ca. 4 on a flowering shoot linear or elliptic-lanceolate, to 4–8 × 1–2 cm, apex broad, unequally bilobed, lobes broad and rounded
Roots	0.6–1 mm diameter	4–6 mm diameter
Inflorescence	to 3 per plant Erect, 3.7–4.1 cm long	2–7 per plant at right angles to the stem, 1–3 cm long
Flowers	2–8, arranged towards the apex of the raceme peduncle 0.4–0.6 mm diameter	2–4, equidistantly arranged in the raceme peduncle 2–4 mm diameter
Bracts	ca. 1 × 1 mm, subtriangular, not embracing the peduncle base 6 mm broad hairy on abaxial side apex not spinulate	ca. 6 mm long, broadly ovate, embracing the peduncle, prickly on abaxial side apex spinulate
Floral parts	median sepal, 8.5–11 × 4.5–5 mm petals 8.3–10 × 4.6–5.2 mm spur without ridges anther ovate with an acute triangular apex, pollinia subspherical, 1–1.2 mm diameter	median sepal to 18 × 10 mm petals to 14 × 8 mm spur with two ridges Anther triangular with a caudate apex pollinia obovoid, 1.5–1.8 mm long, 1 mm broad

[1]Characters based on Pedersen's (1993) description. The description of *Pteroceras johorense* is rather poor due to the rarity of this little known species which is known from two collections only.

aequidistantibus, bractea magna aculeata apice spinuloso, calcare bi-porcato, polliniis obovoideis rima L-forma differt.

Epiphytic herb, stem to 2 cm tall, erect, unbranched. Leaves 4, distichously alternate, 4–8 × 1–2 cm, sessile, articulate, linear to elliptic-lanceolate, slightly wider towards the apex, unequally bilobed, lobes rounded; leaf sheaths imbricate, glabrous, covering the internodes. Inflorescences racemous, from the axils of older leaf sheaths, 2–7, unbranched, at right angles to the stem, 1–3 cm long; peduncle terete, ca. 4 mm diameter, gray, densely covered with soft brown prickles; bracts ca. 6 mm long, persistent, broadly ovate, spinulose at apex, prickly on abaxial side; base 6 mm wide, more or less sheathing the peduncle; flowers 2–4, sessile, spirally alternating (one open at a time). Sepals and petals free, spreading, sparsely prickly on abaxial side, grayish-white; median sepal ca. 1.8 × 1 cm, laterals adnate to the column foot, elliptic-obovate, apex acute; petals ca. 1.4 × 0.8 cm, oblong-obovate, base rounded, glabrous or slightly muricate on abaxial side. Labellum to 6 mm long, side lobes 4 × 3 mm, embracing the column before anthesis and spreading (open) after anthesis, apical part widened, apex obliquely rounded, midlobe small, with a porrect spur. Spur saccate, ca. 3 mm across and 2-toothed at mouth, apex rounded with 2 dorsal ridges,

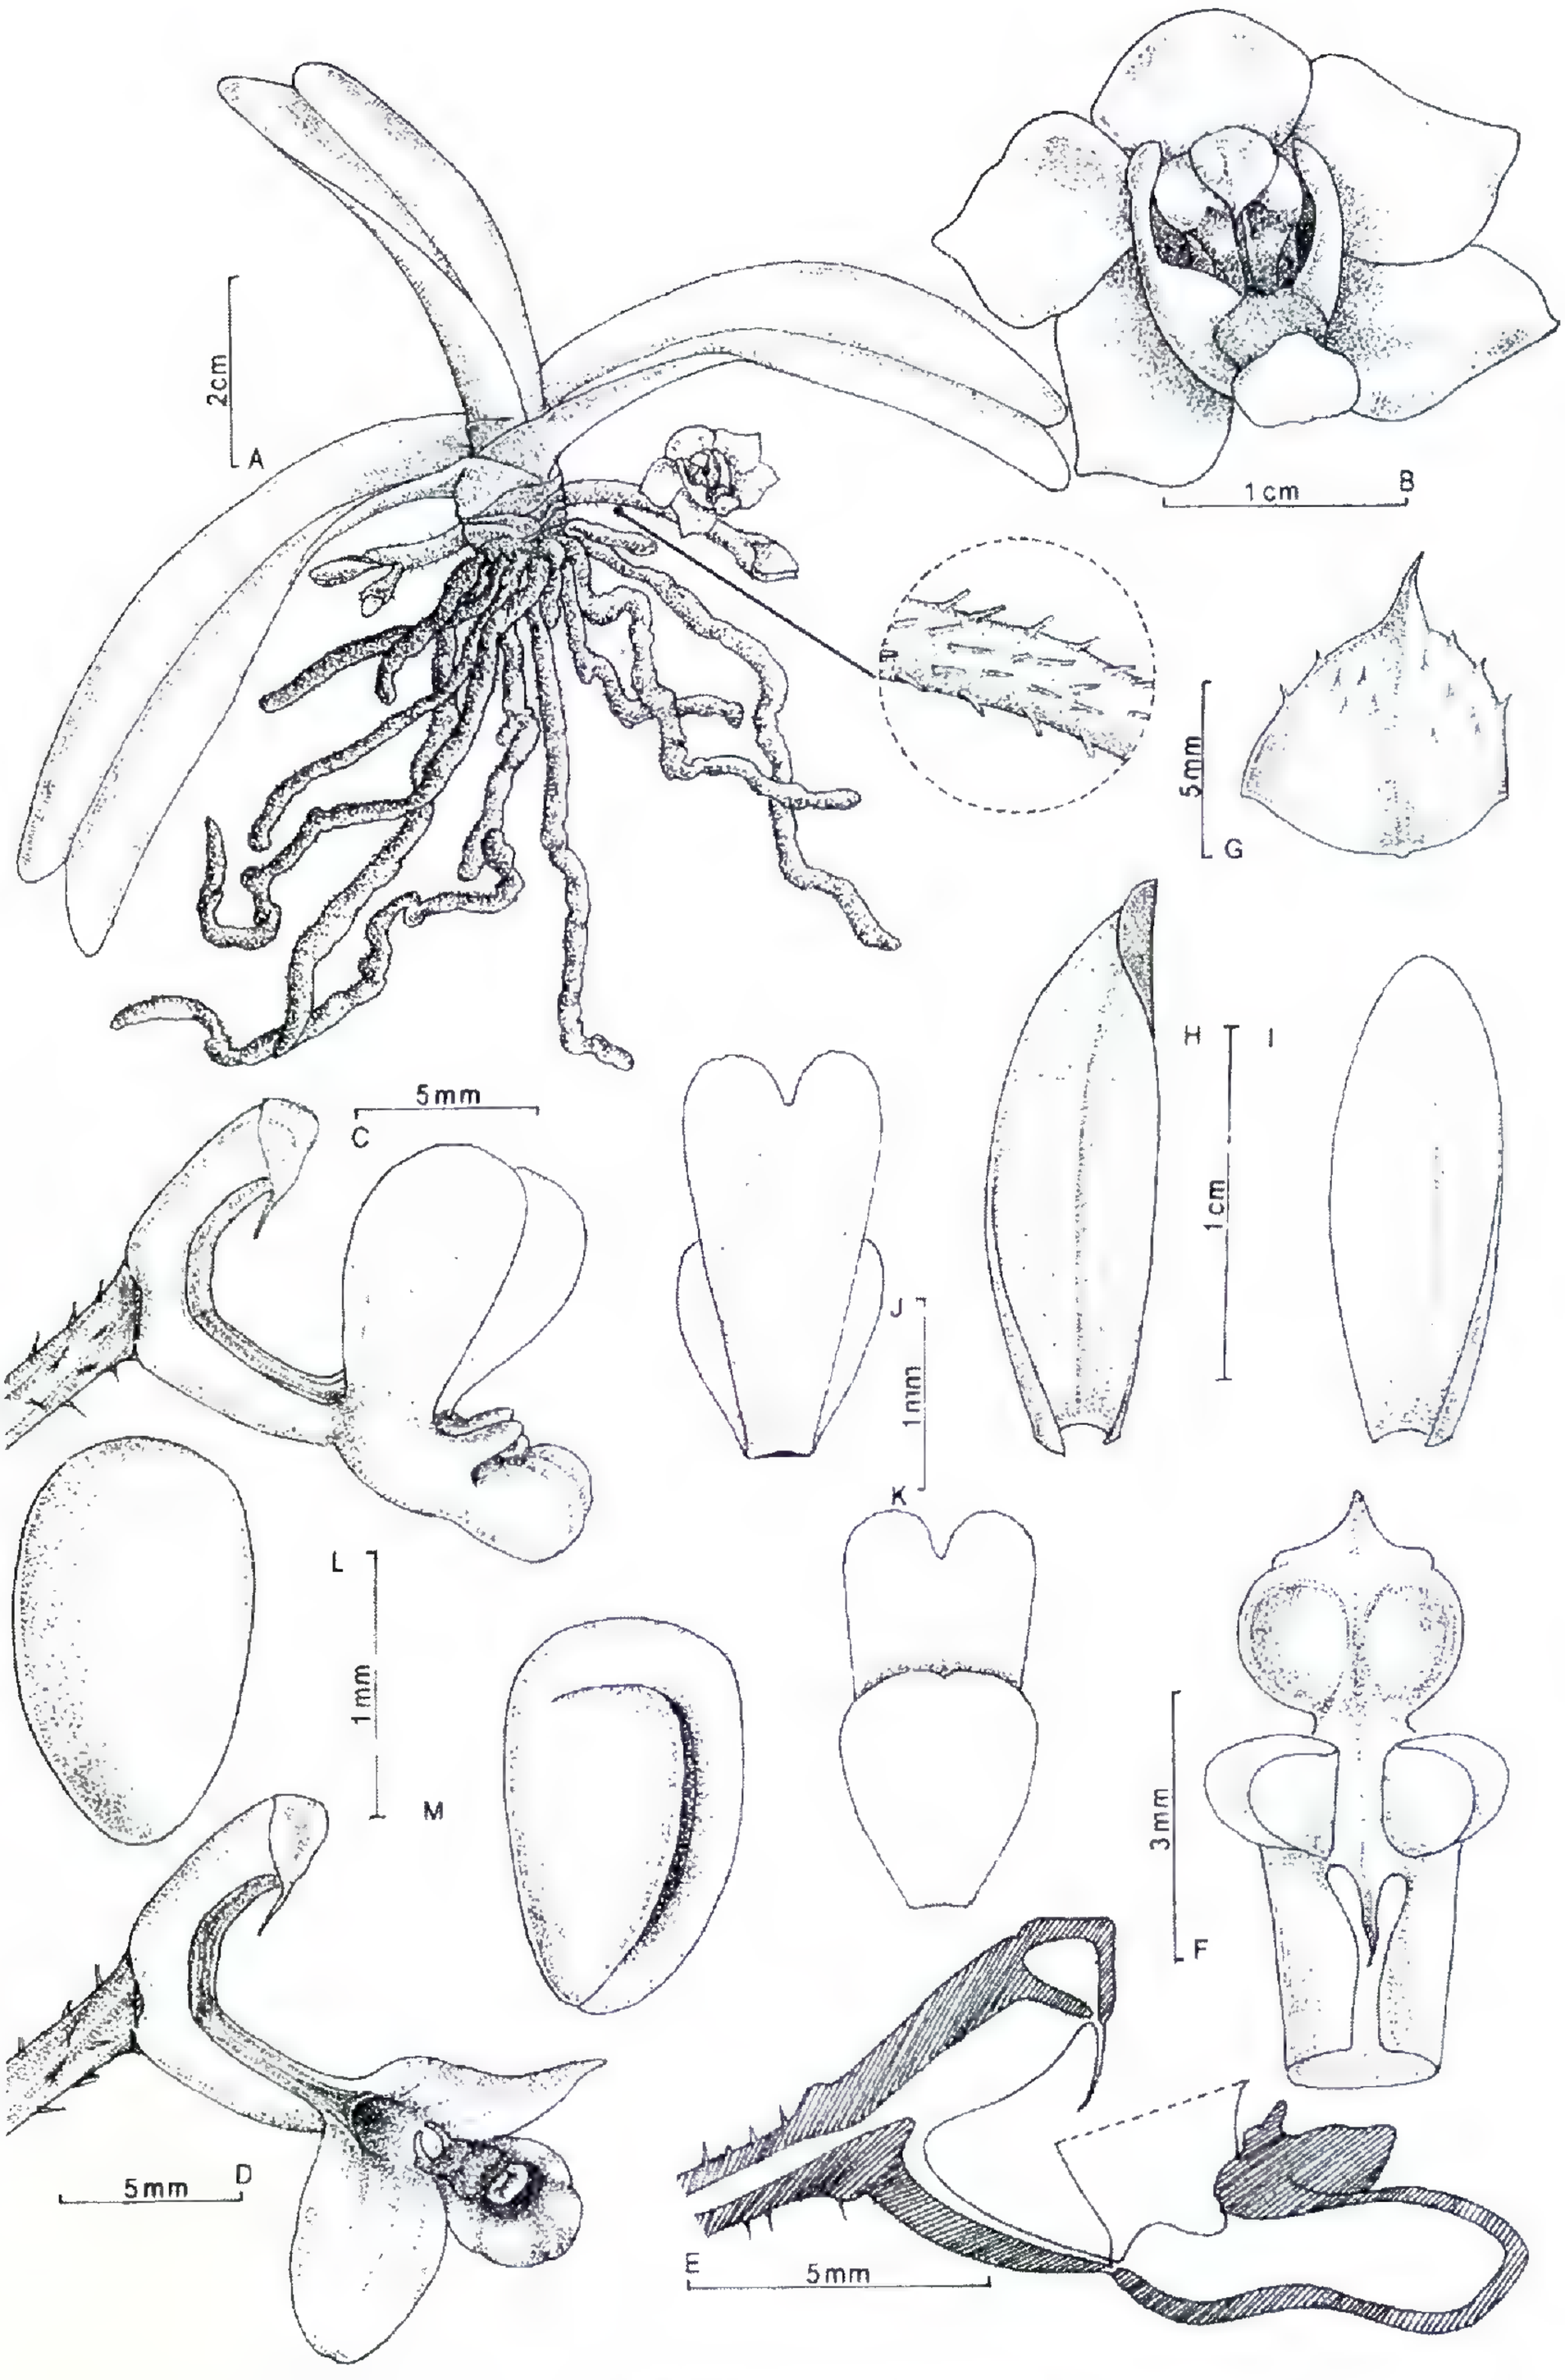

Fig. 1. *Pteroceras monsooniae* Sasidharan & Sujanapal. **A.** Habit; **B.** Flower; **C.** & **D.** Column with lip (dorsal and ventral view); **E.** Flower L.S. (sepals and petals removed); **F.** Column; **G.** Bract; **H.** Sepal; **I.** Petal; **J.** & **K.** Stipe with viscidium (dorsal and ventral view); **L. & M.** Pollinia.

lower ridge yellowish, ca. 2 mm; rostellum ca. 3 mm, deeply bifid 3 mm, clinandrium 3 mm diameter, apiculum 2 mm long. Anther terminal, triangular with a caudate apex, strongly incumbent, dehiscing ventrally, to form 2 flaps; pollinia 2, obovoid, 1.5–1.8 × 1 mm, deeply cleft, stipe ca. 2 mm long, narrowed towards the base, bilobed at apex, lobes rounded, viscidium obovate, to 1 mm long, broader than the stipe. Ovary ca. 1 cm, terete, twisted to the left, slightly 6-ribbed, sparsely echinate. Capsule ellipsoid, to 2.8 × 1.6 cm, 6-ribbed depressed at apex (Fig. 1).

Note.—The flower has a two-ridged spur with an yellowish neck (like the head of a honey bee) which attracts insects during anthesis. The flowers are ephemeral and withering after 8–10 hours. However, the floral parts continue to be attached to the ovary during the fruit development.

Flowering and Fruiting.—May–June, usually flowering with the onset of the southwest monsoon.

Etymology.—Specific epithet of the new taxon is based on the flowering season.

Distribution.—Known only from the type locality

Habitat.—This small monopodial epiphyte is growing ± 1100 m above sea level on trees like *Phyllanthus emblica* L. and *Syzygium cumini* (L.) Skeels along the ecotone area of grassland. Other common trees in the locality are *Cinnamomum sulphuratum* Nees, *Ficus tinctoria* Forst. f. ssp. *parasitica* (Koen. ex Willd.) Corner, *Xantolis tomentosa* (Roxb.) Rafin. var. *elengioides* (DC.) Vajra., etc. The locality constitutes a continuation of the Coimbatore plateau of Deccan which is subjected to high velocity of wind and humidity. Therefore the trees are mostly stunted and clothed with dense moss growth.

PARATYPE: **INDIA. Kerala. Palakkad district:** Parambikulam Wildlife Sanctuary, 10°32'226" N, 76°86'552" E, 1180 m, 19 May 2001 *Sujanapal KFRI 30596* (KFRI).

ACKNOWLEDGMENTS

Our sincere thanks to the Kerala Forest Department (Wildlife) for financial assistance, Wildlife Warden and Staff of Parambikulam Wildlife Sanctuary for the help rendered during the study. We are also thankful to C. Sathish Kumar, TBGRI, Thiruvananthapuram for providing literature and critical comments, Henrik Ærenlund Pedersen, University of Copenhagen, Denmark for commenting on our material, J.F. Veldkamp, Rijksherbarium for the Latin diagnosis, and V.B. Sajeev for the illustration.

ABSTRACT

A new species of Symplocaceae, *Symplocos kothayarensis* Sundaresan, Jothi, Rajkumar & Manickam from the Southern Western Ghats of Tamil Nadu, India is described and illustrated.

KEY WORDS: Symplocaceae, *Symplocos kothayarensis*, Tamil Nadu, India.

RESUMEN

Se describe y se ilustra una especie nueva de Symplocaceae, *Symplocos kothayarensis* Sundaresan, Jothi, Rajkumar & Manickam del suroeste de Ghats de Tamil Nadu, India.

INTRODUCTION

The family Symplocaceae comprises four genera (fide Index Nominum Genericorum; ex: Bobu, Dicalix, Cordyloblaste) and 500 species distributed in the tropical and subtropical regions, except Africa (Ahmedullah & Nayar 1986). They occur in the eastern parts of the Old World, reaching from Bombay in the West to Fiji in the east and from Manchuria in the north to New South Wales and Lord Howe Island in the south. In the New World the species occur from the state of Washington to southern Brazil (Nooteboom 1981).

The genus *Symplocos* Jacq. is represented in India by ca. 45 species. Among these, 13 species and one variety are endemic to peninsular India (Ahmedullah & Nayar 1986). In Tamil Nadu alone the genus *Symplocos* is represented by 10 species and six subspecies (Gopalan 1987).

The southern section of the Western Ghats in India is by far the richest floristic area with a concentration of endemic taxa (Ahmedullah & Nayar 1986). The Tirunelveli hills which include the "Agasthiyamalai' hills, is a remarkable

micro endemic center and one of the hot spots of the Indian flora (Nayar 1996) and attested by IUCN as CPD CITE IS7 (Davis et al. 1994).

During the preparation of the family Symplocaceae for the flora of Tirunelveli hills, one specimen was observed with striking differences belonging to the genus *Symplocos* Jacq. On critical examination, it was found to be a new species, and is described and illustrated here.

Symplocos kothayarensis Sundaresan, Jothi, Rajkumar & Manickam, sp. nov. (**Fig. 1**). TYPE: INDIA. TAMIL NADU. TIRUNELVELI HILLS. KANYAKUMARI DT.: Kothayar near Muthukuzhivayal, 1450 m, 12 Mar 1998, *Sundaresan 14968* (HOLOTYPE: XCH; ISOTYPE: MH).

Symplocos pulchrae arte affinis, sed foliis obovato-oblongis, obtusis; racemes curtioribus; disco glabrato et stylo ad basim glabrato differt.

Small trees to 2(–3)m tall; branchlets fulvous tawny hairy. Leaves simple, alternate, coriaceous, oblong-obovate, 6–9 × 2–4 cm, entire or serrate or half serrate at margin, the nerves ca. 6 pairs, faintly prominent, glabrous above, sparsely hairy beneath, the apex obtuse, emarginate, base acute-subobtuse; petioles ca. 2mm long, thick, bristly tawny hairy. Fowers ca. 15 in condensed axillary racemes, ca. 1cm long; bracts ovate, ca. 2.3 × 1.2mm long, obtuse at apex, densely villous without, glabrous within, persistent; flowers sessile or shortly pedicellate. Calyx tube ca. 1 mm long, with long appressed hairs; lobes 5, ovate, obtuse or subacute at apex, appressed hairy without, glabrous within. Corolla white, lobes 5, ovate-elliptic, apex subacute-obtuse, ca. 3.2 mm long. Stamens ca. 30, connate at the base, filaments free, ca. 2–2.5mm long; anthers 2-celled, ca. 0.5 mm long, Ovary ca. 1.3 mm long, hairy, 3-locular; ovules 2–3; styles stout, ca. 3mm long; stigma capitate; disc 5-lobed, glandular, glabrous. Fruits not seen.

Distribution.—*Symplocos kothayarensis* is endemic to the southern part of Western Ghats, Tamil Nadu, India and is known only from the type locality, Kothayar hills of Tirunelveli hills near Muthukuzhivayal in Kanyakumari District of Tamil Nadu.

Ecology and phenology.—This species grows at 1450 m elevation in the dense evergreen forests along with the species like *Cullenia exarillata* Robyns, *Elaeocarpus serratus* L., *Mallotus philippensis* (Lam.) Muell.-Arg. var. *philippensis*, *Artocarpus heterophyllus* Lam. *Symplocos cochinchinensis* (Lour.) Moore subsp. *laurina* (Retz.) Nooteb. etc....; flowering late February to April.

Etymology.—The species is named after its type locality.

Symplocos kothayarensis is closely allied to *S. pulchra* Wight but it differs in the obovate-oblong, obtuse leaves, short racemes, and glabrous disc and style base.

IDENTIFICATION KEY TO *SYMPLOCOS KOTHAYARENSIS*

1. Diffuse shrubs. Leaves membranous, oblong-lanceolate, apex long acuminate, base rounded or subcordate. Racemes > 2 cm. Disc and style base hairy _____ **S. pulchra**
1. Small trees, Leaves coriaceous, obovate-oblong, apex obtuse, emarginate, base acute subobtuse. Racemes < 1 cm. Disc and style base glabrous _____ **S. kothayarensis**

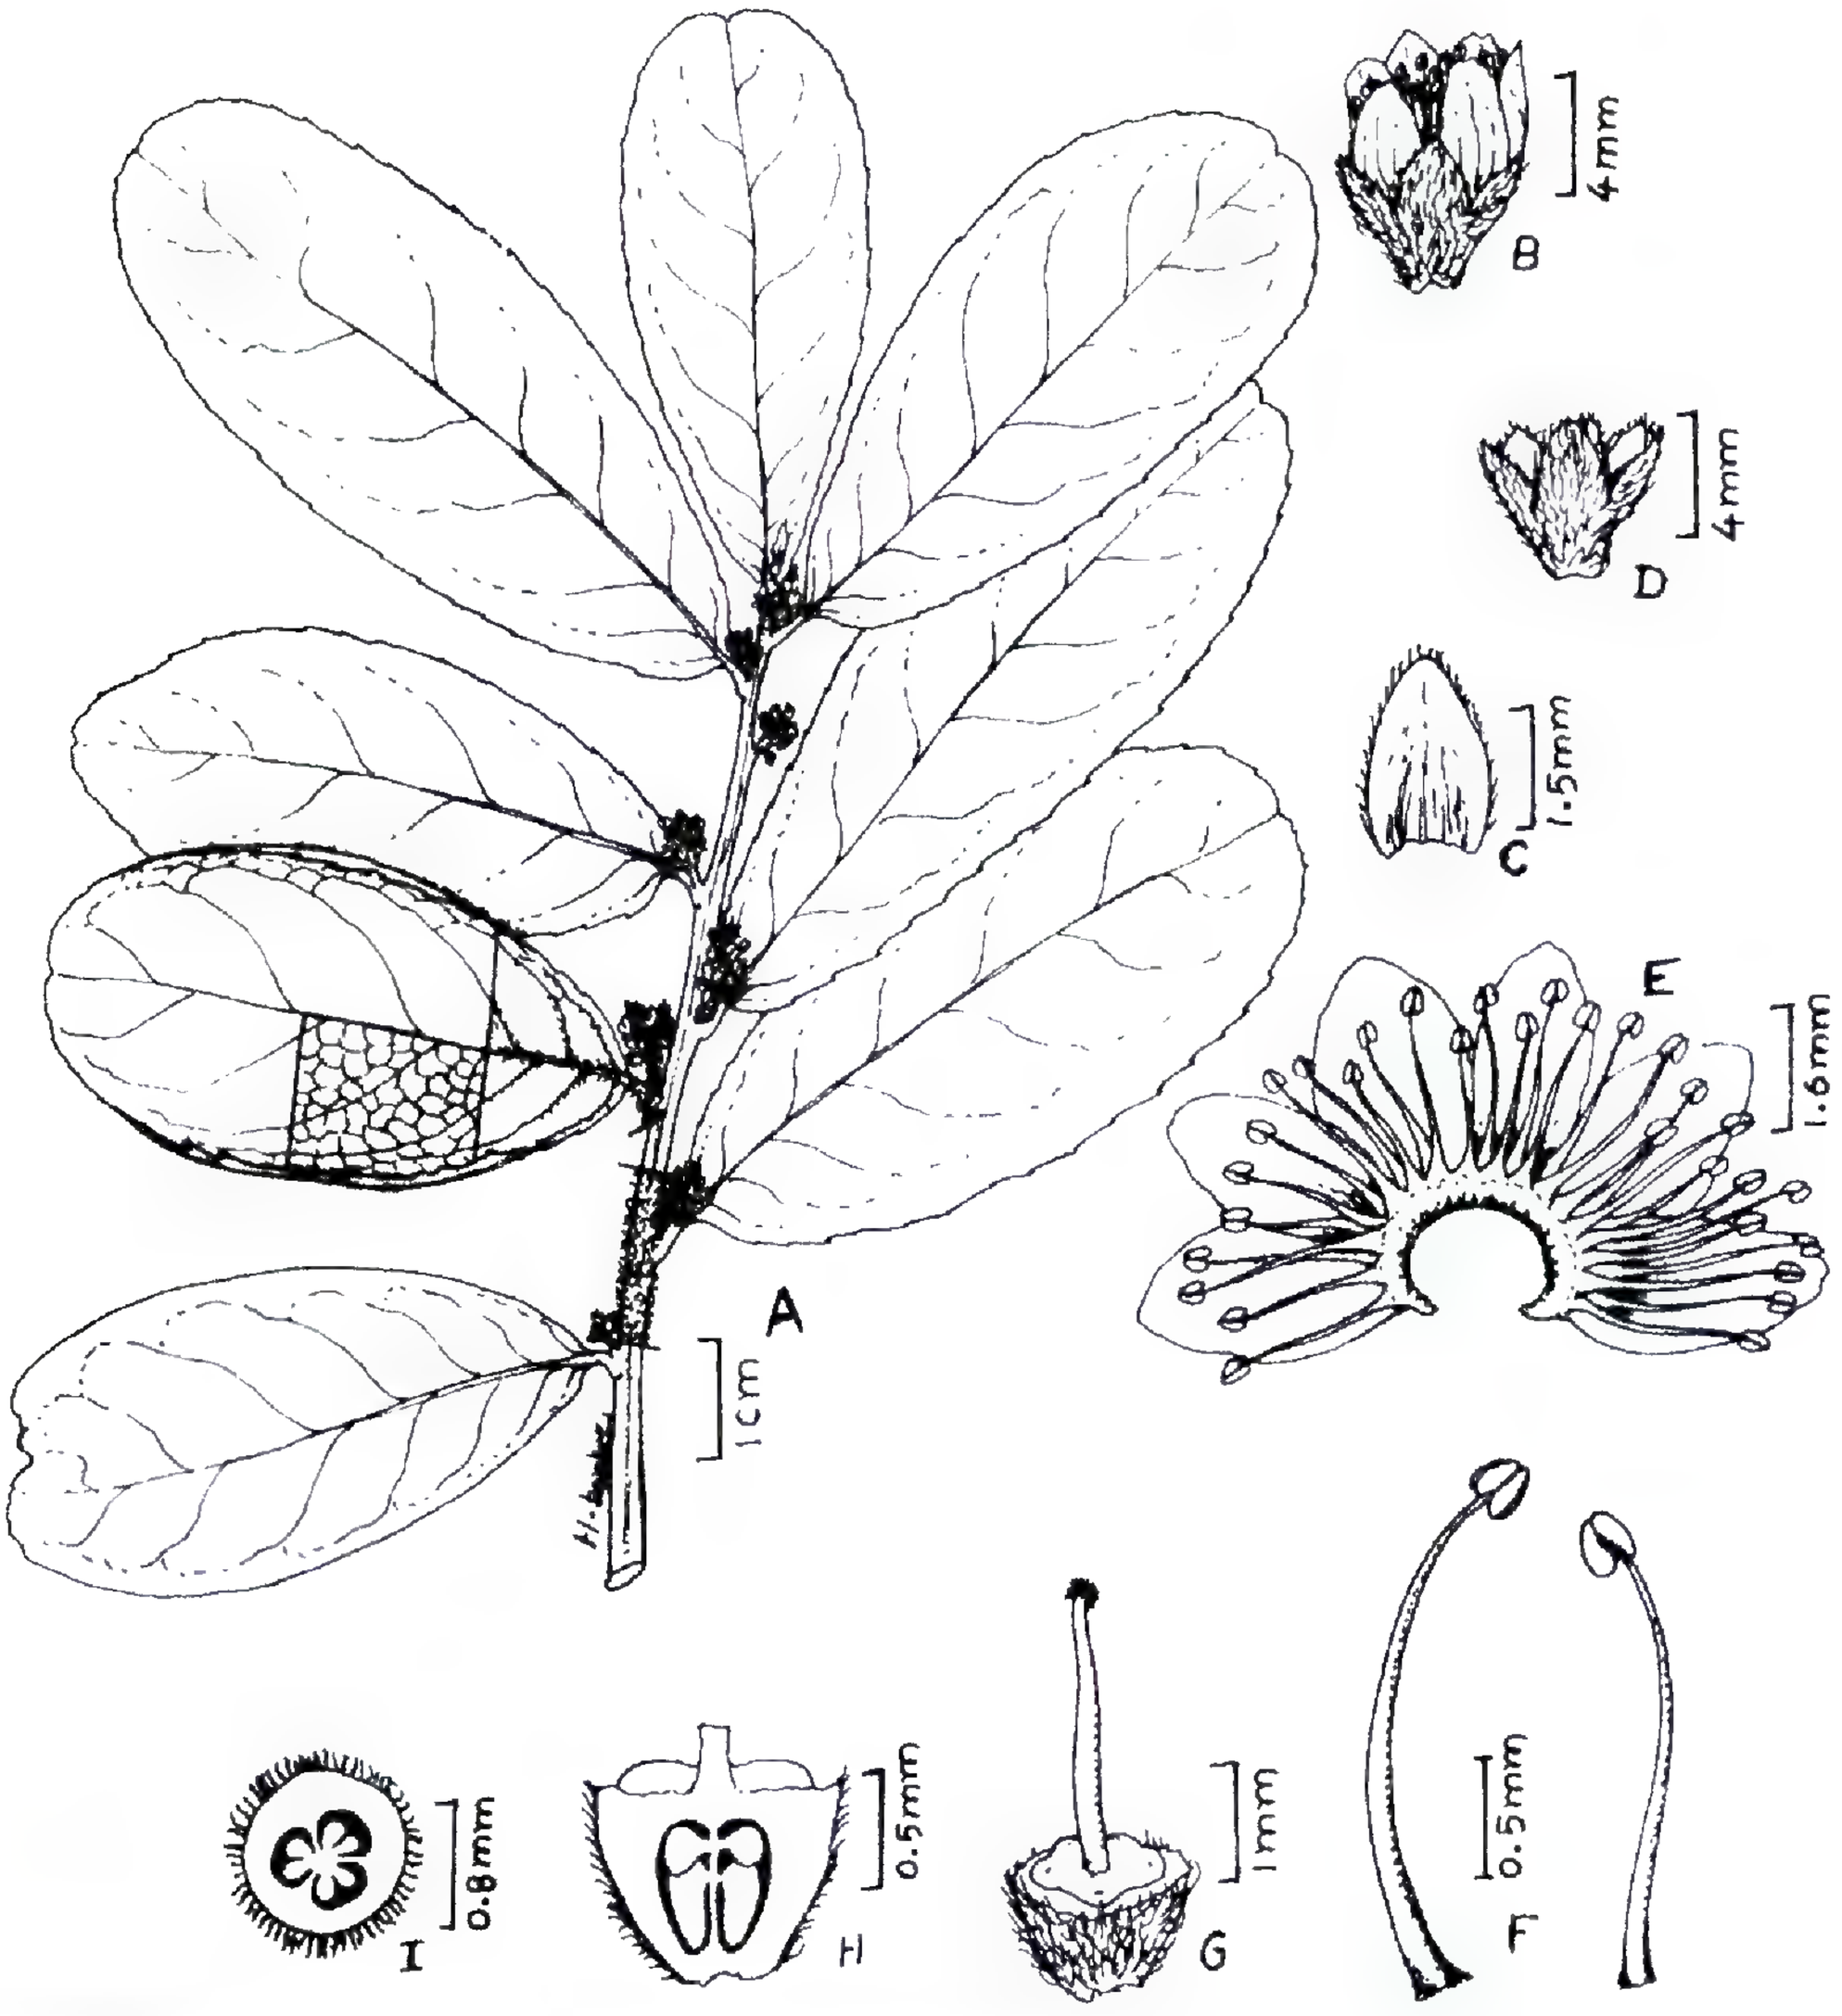

FIG. 1. *Symplocos kothayarensis*. **A.** Flowering shoot. **B.** Flowers. **C.** Bracts. **D.** Calyx. **E.** Corolla split open. **F.** Stamens. **G.** pistil with disc. **H.** Ovary (long. section). **I.** Ovary (cross section) drawn from the type by H. Sankar.

ACKNOWLEDGMENTS

We would like to thank V.J. Nair, Ex Joint Director, Botanical Survey of India for his valuable comments on our specimen and for the Latin diagnosis. We are thankful to the Tamil Nadu Forest Department for allowing us to undertake fieldwork. This work was supported by University Grants Commission (UGC). The illustration was prepared by H. Sankar, CBB, St. Xavier's College, Palayamkottai. We also extend our thanks to the two anonymous referees for their suggestions in the earlier manuscript.

SINOPSIS DEL GÉNERO *MELIOSMA* (SABIACEAE) EN COSTA RICA Y PANAMÁ, CON TRES NUEVAS ESPECIES

J. Francisco Morales

Instituto Nacional de Biodiversidad (INBio)
Apto 22-3100
Santo Domingo de Heredia, COSTA RICA

RESUMEN

Se presenta una sinopsis del género *Meliosma* (Sabiaceae) en Costa Rica y Panamá. Tres nuevas especies, *Meliosma chiriquensis*, *M. clandestina* y *M. depressiva* son descritas e ilustradas.

ABSTRACT

A synopsis of the Costa Rican and Panamanian species of *Meliosma* (Sabiaceae) is presented here. *Meliosma chiriquensis*, *M. clandestina*, and *M. depressiva* are described and illustrated and their relationships are discussed.

El género *Meliosma* (Sabiaceae) es un género respresentado por cerca de 15 especies en los trópicos asiáticos y 40 en el neotrópico (Gentry 1980). Todas las especies estan restringidas a zonas de bosque húmedo, donde se pueden reconocer fácilmente por sus hojas simples alternas a subopuestas o raramente subverticiladas, con pecíolos pulvinulados y por sus frutos, con secreción gomosa al cortarse cuando maduros, persistentes por largo tiempo en el árbol, inclusive hasta 1 año despúes de madurar.

En vista de la ausencia de trabajos taxonómicos monográficos recientes para la región de Mesoamérica y la presencia de varias especies aún no descritas encontradas en el proceso de la elaboración del tratamiento de Sabiaceae para el Manual de las Plantas de Costa Rica, una sinopsis del género *Meliosma* en Costa Rica y Panamá se presenta a continuación, incluyendo distribución y datos fenológicos; en aquellos casos de especies recientemente registradas, nuevos reportes o de complejos taxonómicos de especies afines, se incluyen los especímenes examinados más representativos. En virtud que los frutos en este género persisten durante largo tiempo en el árbol despúes de producidos y las colecciones no clarifican la presencia de frutos maduros o ya secos desde hace largo tiempo, he decidido no incluir datos sobre la fructificación en las descripciones.

CLAVE PARA LAS ESPECIES DE *MELIOSMA* EN COSTA RICA Y PANAMÁ

1. Hojas largamente pecioladas, la mayoría de los pecíolos más de 4.5 cm largo (rara vez 4 cm en hojas muy jovenes).
   2. Hojas cordadas basalmente; sépalos 1.5 mm largo _____ **M. cordata**

SIDA 20(3): 931–943. 2003

2. Hojas cuneadas, obtusas a redondeadas basalmente; sépalos 0.5–1 mm largo.
   3. Hojas densamente puberulentas en el envés, más evidente a lo largo de los nervios; flores rojo-vino a rojo-marrón; bosques en Cordilleras 1600–2000 m _____ **M. depressiva**
   3. Hojas glabras o glabrecentes en el envés; flores anaranjado crema a anaranjadas; bosques en llanuras húmedas y filas costeras bajo los 600 (1000) m _____ **M. allenii**
1. Hojas subsésiles a muy cortamente pecioladas, pecíolos usualmente menos de 4 cm largo.
   4. Hojas densa a moderadamente puberulentas en el envés, la pubescencia diminuta, pero regularmente esparcida por toda la lámina.
      5. Láminas levemente cordadas basalmente _____ **M. subcordata**
      5. Láminas cuneadas a obtusas basalmente.
         6. Pecíolos menos de 9 mm _____ **M. brenesii**
         6. Pecíolos 12–35 mm largo _____ **M. occidentalis**
   4. Hojas glabras a glabradas en el envés o con la pubescencia restringida solo a las nervaduras _____ **(M. occidentalis)**
      7. Hojas largamente lineares _____ **M. linearifolia**
      7. Hojas no lineares, de variadas formas.
         8. Flores conspicuamente pediceladas, flores no dispuestas en glomérulos; frutos menos 1 cm diámetro, globosos _____ **M. idiopoda**
         8. Flores sésiles, subsésiles o inconspicuamente pediceladas, generalmente dispuestas en glomérulos; frutos más 1.5 cm diámetro, obovoides a piriformes.
            9. Ramos laterales de la inflorescencias inconspicuos, inflorescencias pareciendo racemosas o espiciformes _____ **M. grandiflora**
            9. Ramos laterales de la inflorescencias conspicuamente desarrollados, inflorescencias claramente paniculadas.
               10. Láminas foliares conspicuamente bulladas, revolutas marginalmente en toda su longitud _____ **M. frondosa**
               10. Láminas foliares no bulladas o solo muy levemente, los márgenes no revolutos o solo justo antes de la unión de la lámina con el pecíolo.
                  11. Láminas foliares usualmente revolutas hacia la base, justo antes de la unión del pecíolo y la lámina _____ **M. hartshornii**
                  11. Láminas foliares no revolutas basalmente.
                     12. Inflorescencias mayormente caulifloras, más raramente axilares, glabras, glabradas a muy esparcidamente puberulentas, no ferrugíneas _____ **M. glabrata**
                     12. Inflorescencias mayormente terminales o subterminales, puberulentas o diminutamente ferrugíneo-puberulentas en la antésis.
                        13. Hojas subsésiles, pecíolo menos de 9 mm largo (hasta 12 mm en hojas muy desarrolladas); lámina obovada a angostamente obovada, gradualmente atenuadas hacia el pecíolo, con la base obtusa o redondeada; tallos jovenes algo angulados.
                           14. Lámina (28–)34–68 3 7.5–18 cm; frutos 2.2–2.4 cm largo; pétalos 1–1.5 mm; inflorescencias 17–65 cm largo _____ **M. donnellsmithii**

14. Lámina (7–)10–33(–35) 3 (2–)4–8.5 cm; frutos 1.7–1.8(–2) cm largo; pétalos 2–2.5 mm; inflorescencias 17–26 cm largo _____ **M. clandestina**

13. Hojas pecioladas, pecíolo 1–3.5 cm largo; lámina elíptica, con la base cuneada; tallos jovenes teretes a subteretes.
    15. Inflorescencias con las flores laxamente distribuidas; 100–800(–1200) m _____ **M. occidentalis**
    15. Inflorescencias con las flores densamente aglomeradas; 1000–2300 m.
        16. Inflorescencias con el eje principal glabro a glabrado y los ejes axilares esparcidamente puberulentos, la pubescencia no ferrugínea; 1000–1100 m _____ **M. chiriquensis**
        16. Inflorescencias con el eje principal y los ejes axilares ferrugíneo-puberulento a densamente ferrugíneo-puberulentas; 1100–2300 m _____ **M. vernicosa**

1. Meliosma allenii Standley & L.O. Williams, Ceiba 3:213. 1953. *Meliosma maxima* Standley & L.O. Williams, Ceiba 1:242. 1951, non Standley & Steyermark, 1944. *Meliosma longipetiolata* Standley & L.O. Williams ex Brizicky, Trop. Woods 110:39. 1959. TIPO. Costa Rica. Puntarenas: Palmar Norte, *Allen 5648* (HOLOTIPO: F; ISOTIPOS: F, MO, US).

Distribución.—Costa Rica y Panamá, 0–600(–1000) m. Este nombre ha sido utilizado para algunos especímenes provenientes de Perú y depositados en el Jardín Botánico de Missouri (MO). Sin embargo, probablemente representen otra entidad, dado que la morfología de las hojas y los frutos es diferente. En adición, la mayoría de los especímenes son estériles.

Fenología.—Especímenes con flores han sido recolectados entre Marzo y Junio. Especímenes con frutos se reportan durante Abril a Diciembre.

Una de las especies más comunes en zonas bajas, donde puede llegar a ser bastante común a lo largo de cauces de agua. Solamente existe otra especie con hojas largamente pecioladas en Costa Rica y Panamá, *Meliosma depressiva* (descrita aquí), pero *M. allenii* se reconoce por sus hojas con láminas glabras a glabradas en el envés, flores usualmente anaranjadas a crema-anaranjadas y distribución altitudinal diferente.

2. Meliosma brenesii Standley, Publ. Field Mus. Nat. Hist., Bot Ser. 18:648. 1937. TIPO. COSTA RICA. ALAJUELA: La Palma de San Ramón, 1050 m, *Brenes 5556* (HOLOTIPO: F; ISOTIPOS: CR, NY).

Distribución.—Costa Rica y el Norte de Panamá, 500–1200(–1700) m.

Fenología.—especímenes con flores se han recolectado entre Junio y Agosto.

Dentro del grupo de especies con hojas pubescentes y pecíolos cortos presentes en Costa Rica y Panamá, *Meliosma brenesii* puede ser confundida con *M. subcordata*, con la cual comparte láminas foliares, áreas de distribución geográficas y preferencias ecológicas similares. Sin embargo, *M. brenesii* se puede

reconocer fácilmente por sus hojas con la lámina cuneadas a obtusas en la base, no cordadas en la base.

3. Meliosma chiriquensis J.F. Morales, sp. nov. (**Fig. 1**). TIPO. PANAMÁ. CHIRIQUÍ: vicinity of Fortuna Dam, 11 Feb 1987 (fl), *McPherson 10480* (HOLOTIPO: INB; ISOTIPO: MO).

A *Meliosma vernicosa* cui affinis, foliis subopuesta vel verticillatis, inflorescentiis puberulis differt. Arbor. Folia simplicia, 7.7–11.6 cm × 4–6.2 cm, eliptica, glabrata, subopuesta vel verticillata. Inflorescentia ramiflora, pyramidale paniculata, terminales vel subterminale, floribus sessilis, sepala ciliata, glabrata. Fructus ignotus.

Arbol 18 m; ramas glabras o glabradas. Hojas subopuestas a subverticiladas; pecíolo 2–2.7 cm largo, glabro a glabrado; lámina 7.7–11.6 × 4–6.2 cm, elípticas, redondeadas a raramente emarginadas apicalmente, cuneadas en la base, subcoriáceas, enteras, glabras o glabradas. Inflorescenicas ramifloras, terminales a subterminales, más raramente axilares, piramidal paniculada, esparcidamente puberulentas, especialmente los ejes secundarios, 7–11 cm largo; flores sésiles a subsésiles, sépalos 5, ovados, anchamente agudos a obtusos apicalmente, ciliados marginalmente, pero el resto glabros a glabrados; pétalos blancos, 1.8–2 mm largo, anchamente ovados, glabros; ovario menos de 1 mm largo. Frutos desconocidos.

Distribución.—endémica por el momento al norte de Panamá, pero podría estar presente en el sur de Costa Rica, 1000–1100 m. Conocida únicamente por la colección tipo.

Fenología.—Floración en Enero y Febrero.

Esta especie se encuentra algo relacionada con *Meliosma vernicosa*. Ambas especies comparten inflorescencias con estructuras morfológicas y preferencias ecológicas similares, pero *M. chiriquensis* se reconoce por sus hojas mayormente subopuestas o subverticiladas e inflorescencias mucho más cortas, esparcidamente puberulentas y con la pubescencia no ferrugínea.

4. Meliosma clandestina J.F. Morales, sp. nov. (**Fig. 2**). TIPO. COSTA RICA. SAN JOSÉ: Cantón de Dota, Fila Dota, camino entre San Joaquín y Naranjito, 600 m, Mar 2001 (fl,fr), *Morales 7626* (HOLOTIPO: INB; ISOTIPOS: COL, CR, F,G, K, MEXU, MO, NY).

A *Meliosma donnellsmithii* cui affinis, folia minor, fructus major differt. Arbor. Folia simplicia, (7–)10–33(–35) cm × (2–)4–8.5 cm obovata, glabrata. Inflorescentia ramiflora, paniculata, terminales vel subterminales, floribus sessilis, sepala ciliata, glabrata. Fructus 1.7–1.8(–2) cm × 1.4–1.7 cm, obovoideus.

Arbol 5–11 m; ramas glabradas o muy inconspicua y esparcidamente puberulentas. Hojas alternas a subopuestas en el final de las ramitas; pecíolo 0.2–0.5 cm largo, glabro a glabrado; lámina (7–)10–33(–35) × (2–)4–8.5 cm, obovadas a angostamente obovadas, agudas a acuminadas (raramente obtusas) apicalmente, largamente atenuadas hacia la base, pero redondeadas u obtusas en la base, cartáceas a subcoriáceas, enteras o subenteras y con muy pocos y casi inconspicuos dientes, glabras o glabradas y con solo el nervio central puberulento. Inflorescencias ramifloras, terminales a subterminales, paniculadas,

FIG. 1. *Meliosma chiriquensis* J.F. Morales (*McPherson 10480*, INB). **A.** Hábito.

puberulentas, no ferrugíneas, (8–)17–26 cm largo; flores sésiles a subsésiles y con pedicelos de hasta 1 mm; sépalos 5, ovados, anchamente agudos a obtusos apicalmente, ciliados marginalmente, pero el resto glabro; pétalos amarillos a crema, 2–2.5 mm largo, anchamente ovados, glabros; ovario ca. 1 mm largo. Frutos 1.7–1.8(–2) × 1.4–1.7 cm, obovoide.

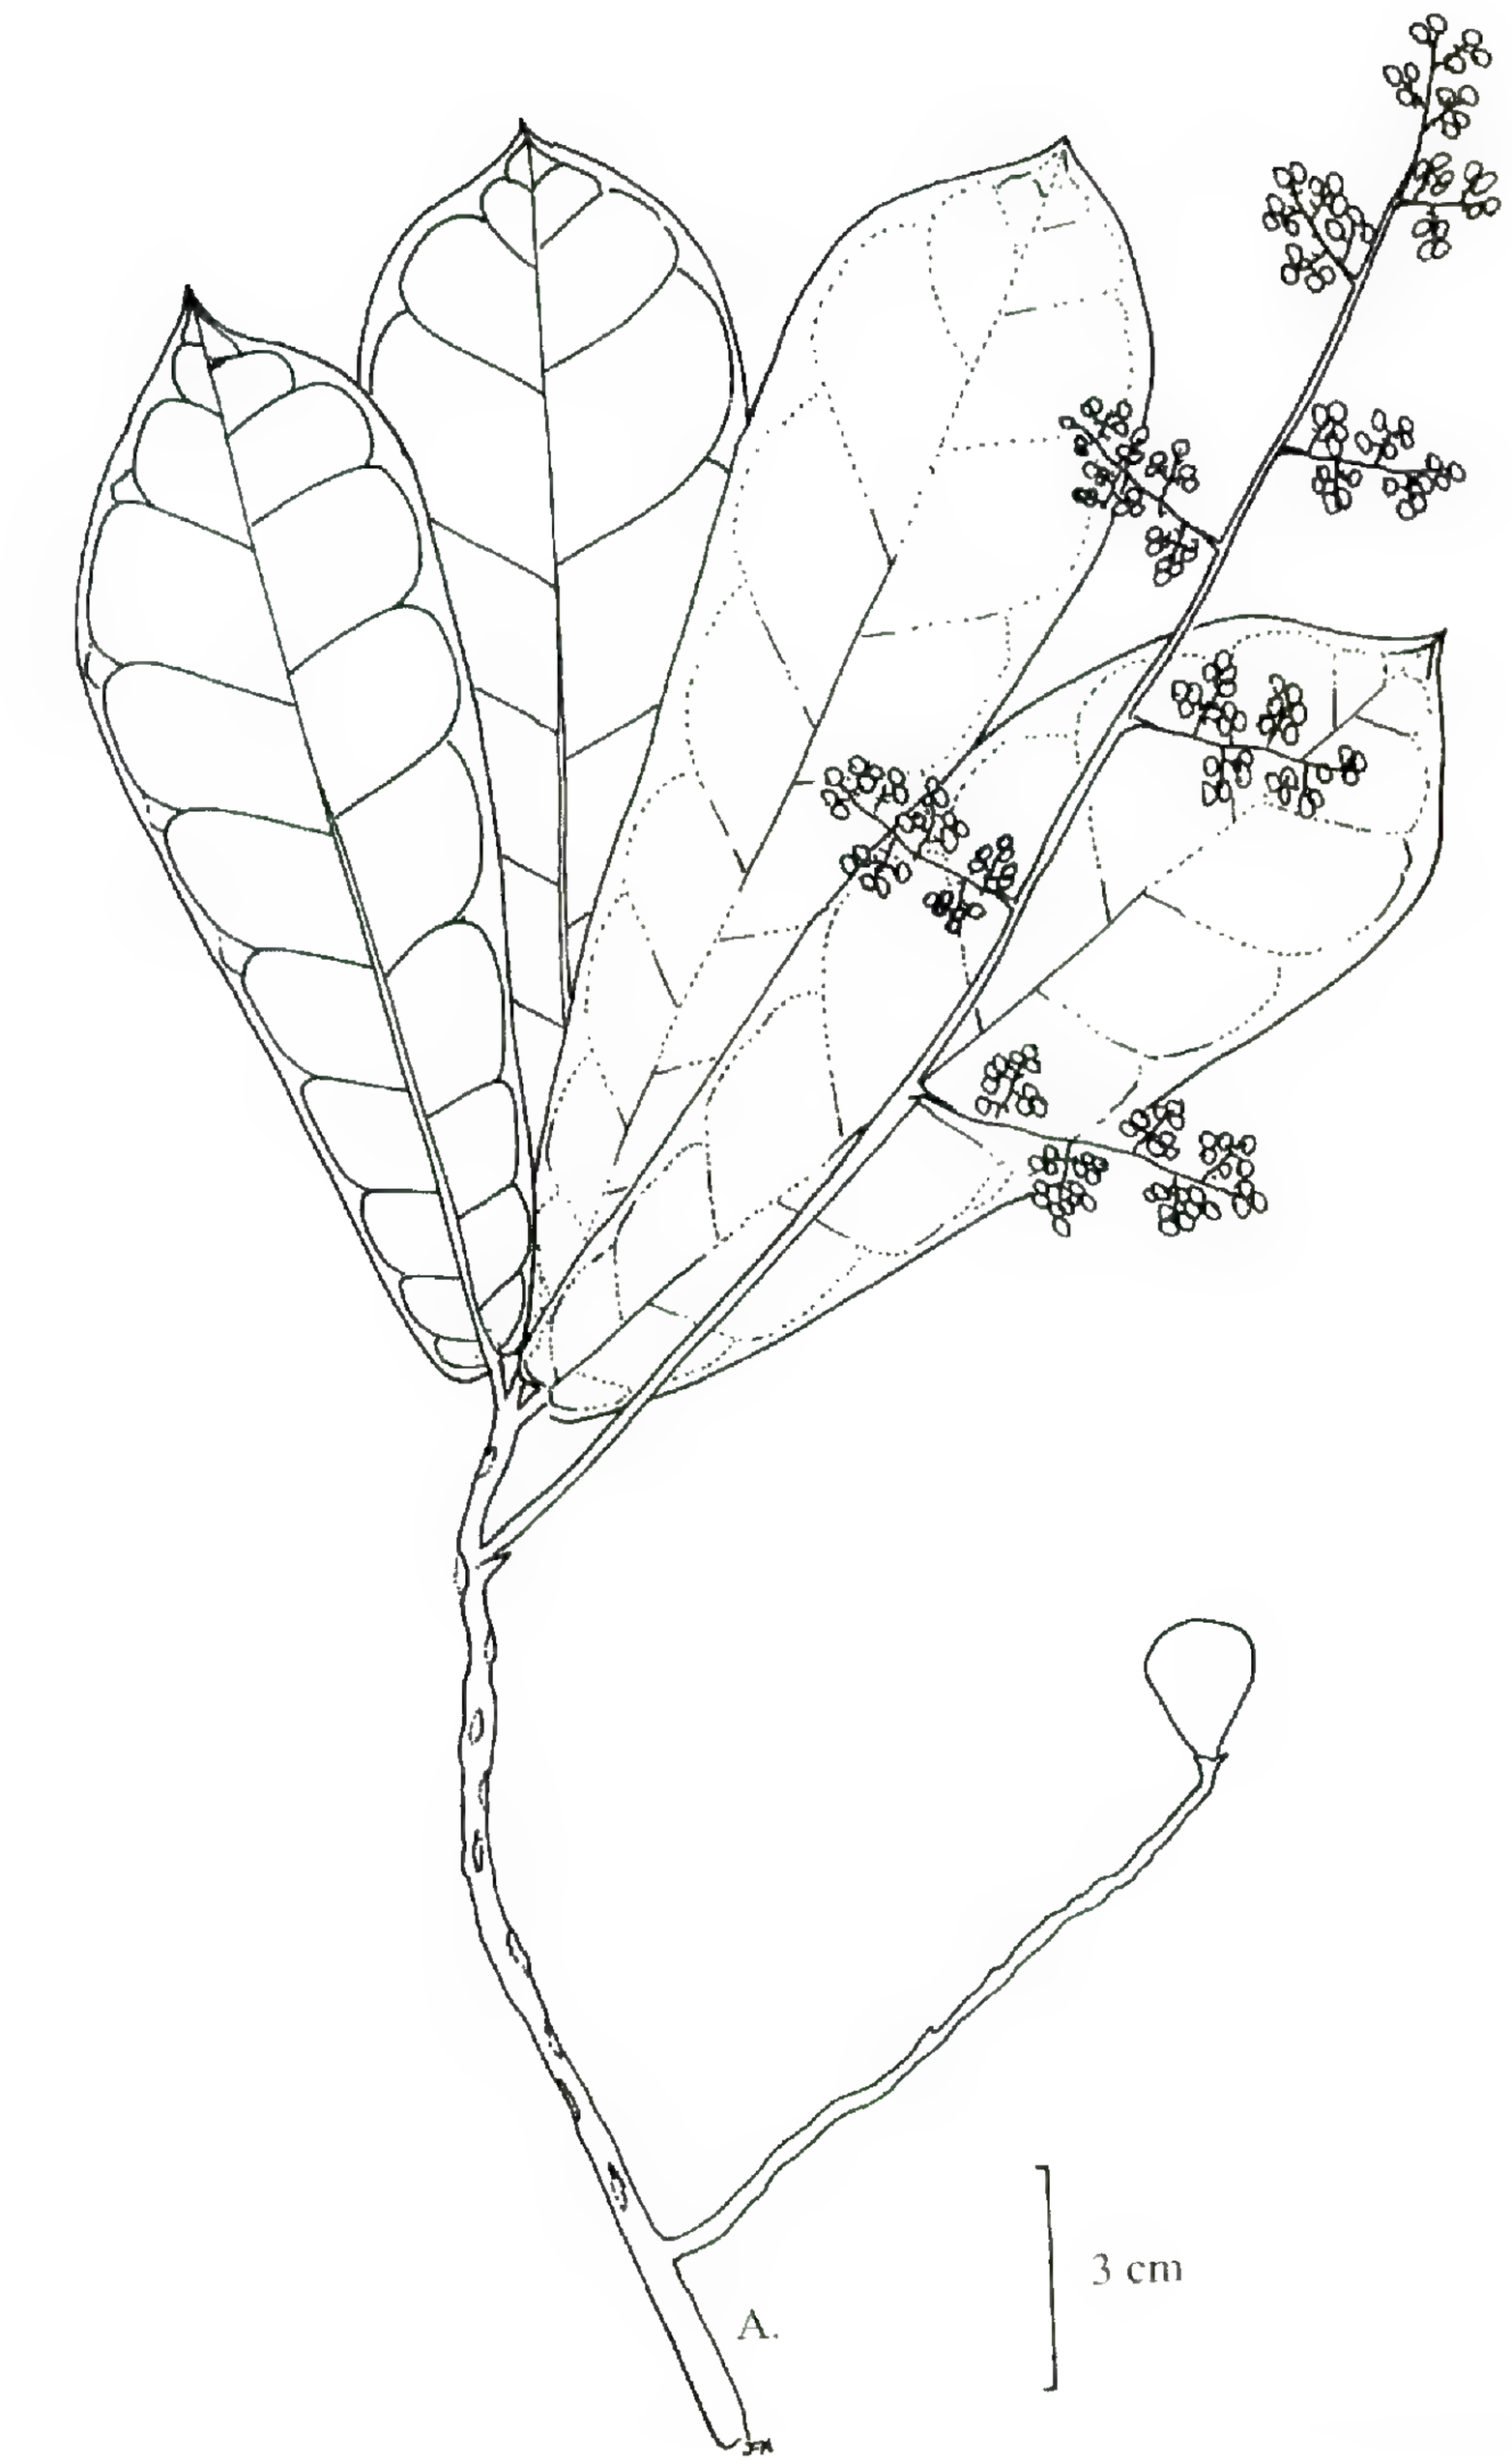

Fig. 2. *Meliosma clandestina* J.F. Morales (*Morales 7626*, INB). **A.** Hábito, inflorescencia y fruto.

Distribución.—Endémica a Costa Rica, en las faldas costeñas del Pacífico Central y Sur y la Península de Osa, 100–900 m.

Fenología.—Especímenes con flores y frutos han sido recolectados entre Julio, Setiembre y Febrero.

Algunos especímenes de esta especie fueron tratados bajo el concepto de

Meliosma donnellsmithii en el tratamiento de Sabiaceae para la Flora de Panamá, pero tal y como Gentry lo mencionó (1980), existían carácteres que sugerían que el material de Costa Rica de la Península de Osa en realidad correspondía a otra especie diferente. Colecciones adicionales acumuladas desde esa época muestran que en efecto se trataba de una especie sin describir. Los caracteres más importantes para separar *M. clandestina* de *M. donnellsmithii*, incluyen frutos y hojas conspicuamente más pequeños y flores más grandes.

PARATIPOS. **COSTA RICA. Puntarenas:** forested slopes above Golfito, 27–28 Ene 1967, *Burger & Mata 4696* (CR, F, MO); Parque Nacional Corcovado, Llorona, 13 Jul 1977, *Liesner 3227* (CR, MO). **San José:** Cantón de Puriscal, Cuenca del Tulín, Fila Cangreja, 15 Set 1998, *Acosta 22* (INB); Reserva Forestal La Cangreja, Mastatal de Puriscal, 22 Jul 1988, *Hammel et al. 17116* (INB, MO); Pérez Zeledón, cuenca del Barú, Fila Tinamastes, 9 Set 1996, *Hammel et al. 20431* (INB, MO); Santa Rosa de Puriscal, 4 Feb 1973, *Poveda 480* (CR).

5. Meliosma cordata A. Gentry, Ann. Missouri Bot. Gard. 67:954. 1980 [1981]. TIPO. PANAMA. VERAGUAS: lower slopes of Cerro Tute, ca. 10. km NW of Santa Fe, 750–1000 m, 19 May 1975 (fr), *Mori 6297* (HOLOTIPO: MO [2 partes]).

Distribución.—Sur de Costa Rica y norte de Panamá, 750–1850 m.

Fenología.—Especímenes con flores han sido recolectados entre Marzo y Abril. Frutos se reportan de Marzo a Mayo.

Esta especie era anteriormente conocida únicamente por la colección tipo, pero ahora es reportada de Costa Rica. Se encuentra bastante relacionada con *Meliosma depressiva* (descrita aquí), pero se reconoce por sus hojas con la lámina basalmente cordada y frutos más pequeños; en adición, sus sépalos y pétalos son más grandes.

Especímenes representativos examinados. **COSTA RICA. Puntarenas:** foothills of the Cordillera de Talamanca, around Tres Colinas, 1800–1850 m, 20 Mar 1984, *Davidse et al. 25672* (INB, MO); Cantón de Buenos Aires, Puesto Tres Colinas, Río Guineo, 17 Set 1996, *Gamboa & Picado 649* (INB, MO).

6. Meliosma depressiva J.F. Morales, sp. nov. (**Fig. 3**). TIPO. COSTA RICA. SAN JOSÉ: Cantón de Aserrí, Fila Bustamante, Hacienda Tiquires, Fila Aguabuena, bosque a camino al Alto La Araña, 1900–2000 m, 11 May 1996 (fl), *Morales & Ulate 5379* (HOLOTIPO: INB; ISOTIPOS: CR, F, MO).

Arbor parva. Folia simplicia, 9–30 cm × 5–12 cm, eliptica, obovata-elíptica vel lanceolata, puberula. Inflorescentia ramiflora vel cauliflora, paniculata, floribus pedicellatis, sepala tomentosa. Fructus 2.2–2.7 cm × 1.6–1.8 cm, obovoideus.

Arboles o arbustos 3–7 m; ramas densamente ferrugíneo-tomentulosos o densamente puberulentos cuando jovenes, glabrados y muy esparcida e inconspicuamente puberulentos con la edad. Hojas alternas a subopuestas en el final de las ramitas; pecíolo 4.5–12 cm largo, raramente menos de 4 cm en hojas inmaduras y jovenes, moderada a esparcidamente puberulento, muy rara vez glabrado; lámina 9–30 × 5–12 cm, elípticas, obovado-elípticas a anchamente lanceoladas, agudas a acuminadas apicalmente, obtusas en la base, subcoriáceas, enteras o con muy pocos e inconspicuos dientes, esparcidamente puberulentas en el envés, la lámina glabrada cuando vieja, y con la pubescencia restringida al nervio central puberulento. Inflorescencias ramifloras a cauliflloras, axilares,

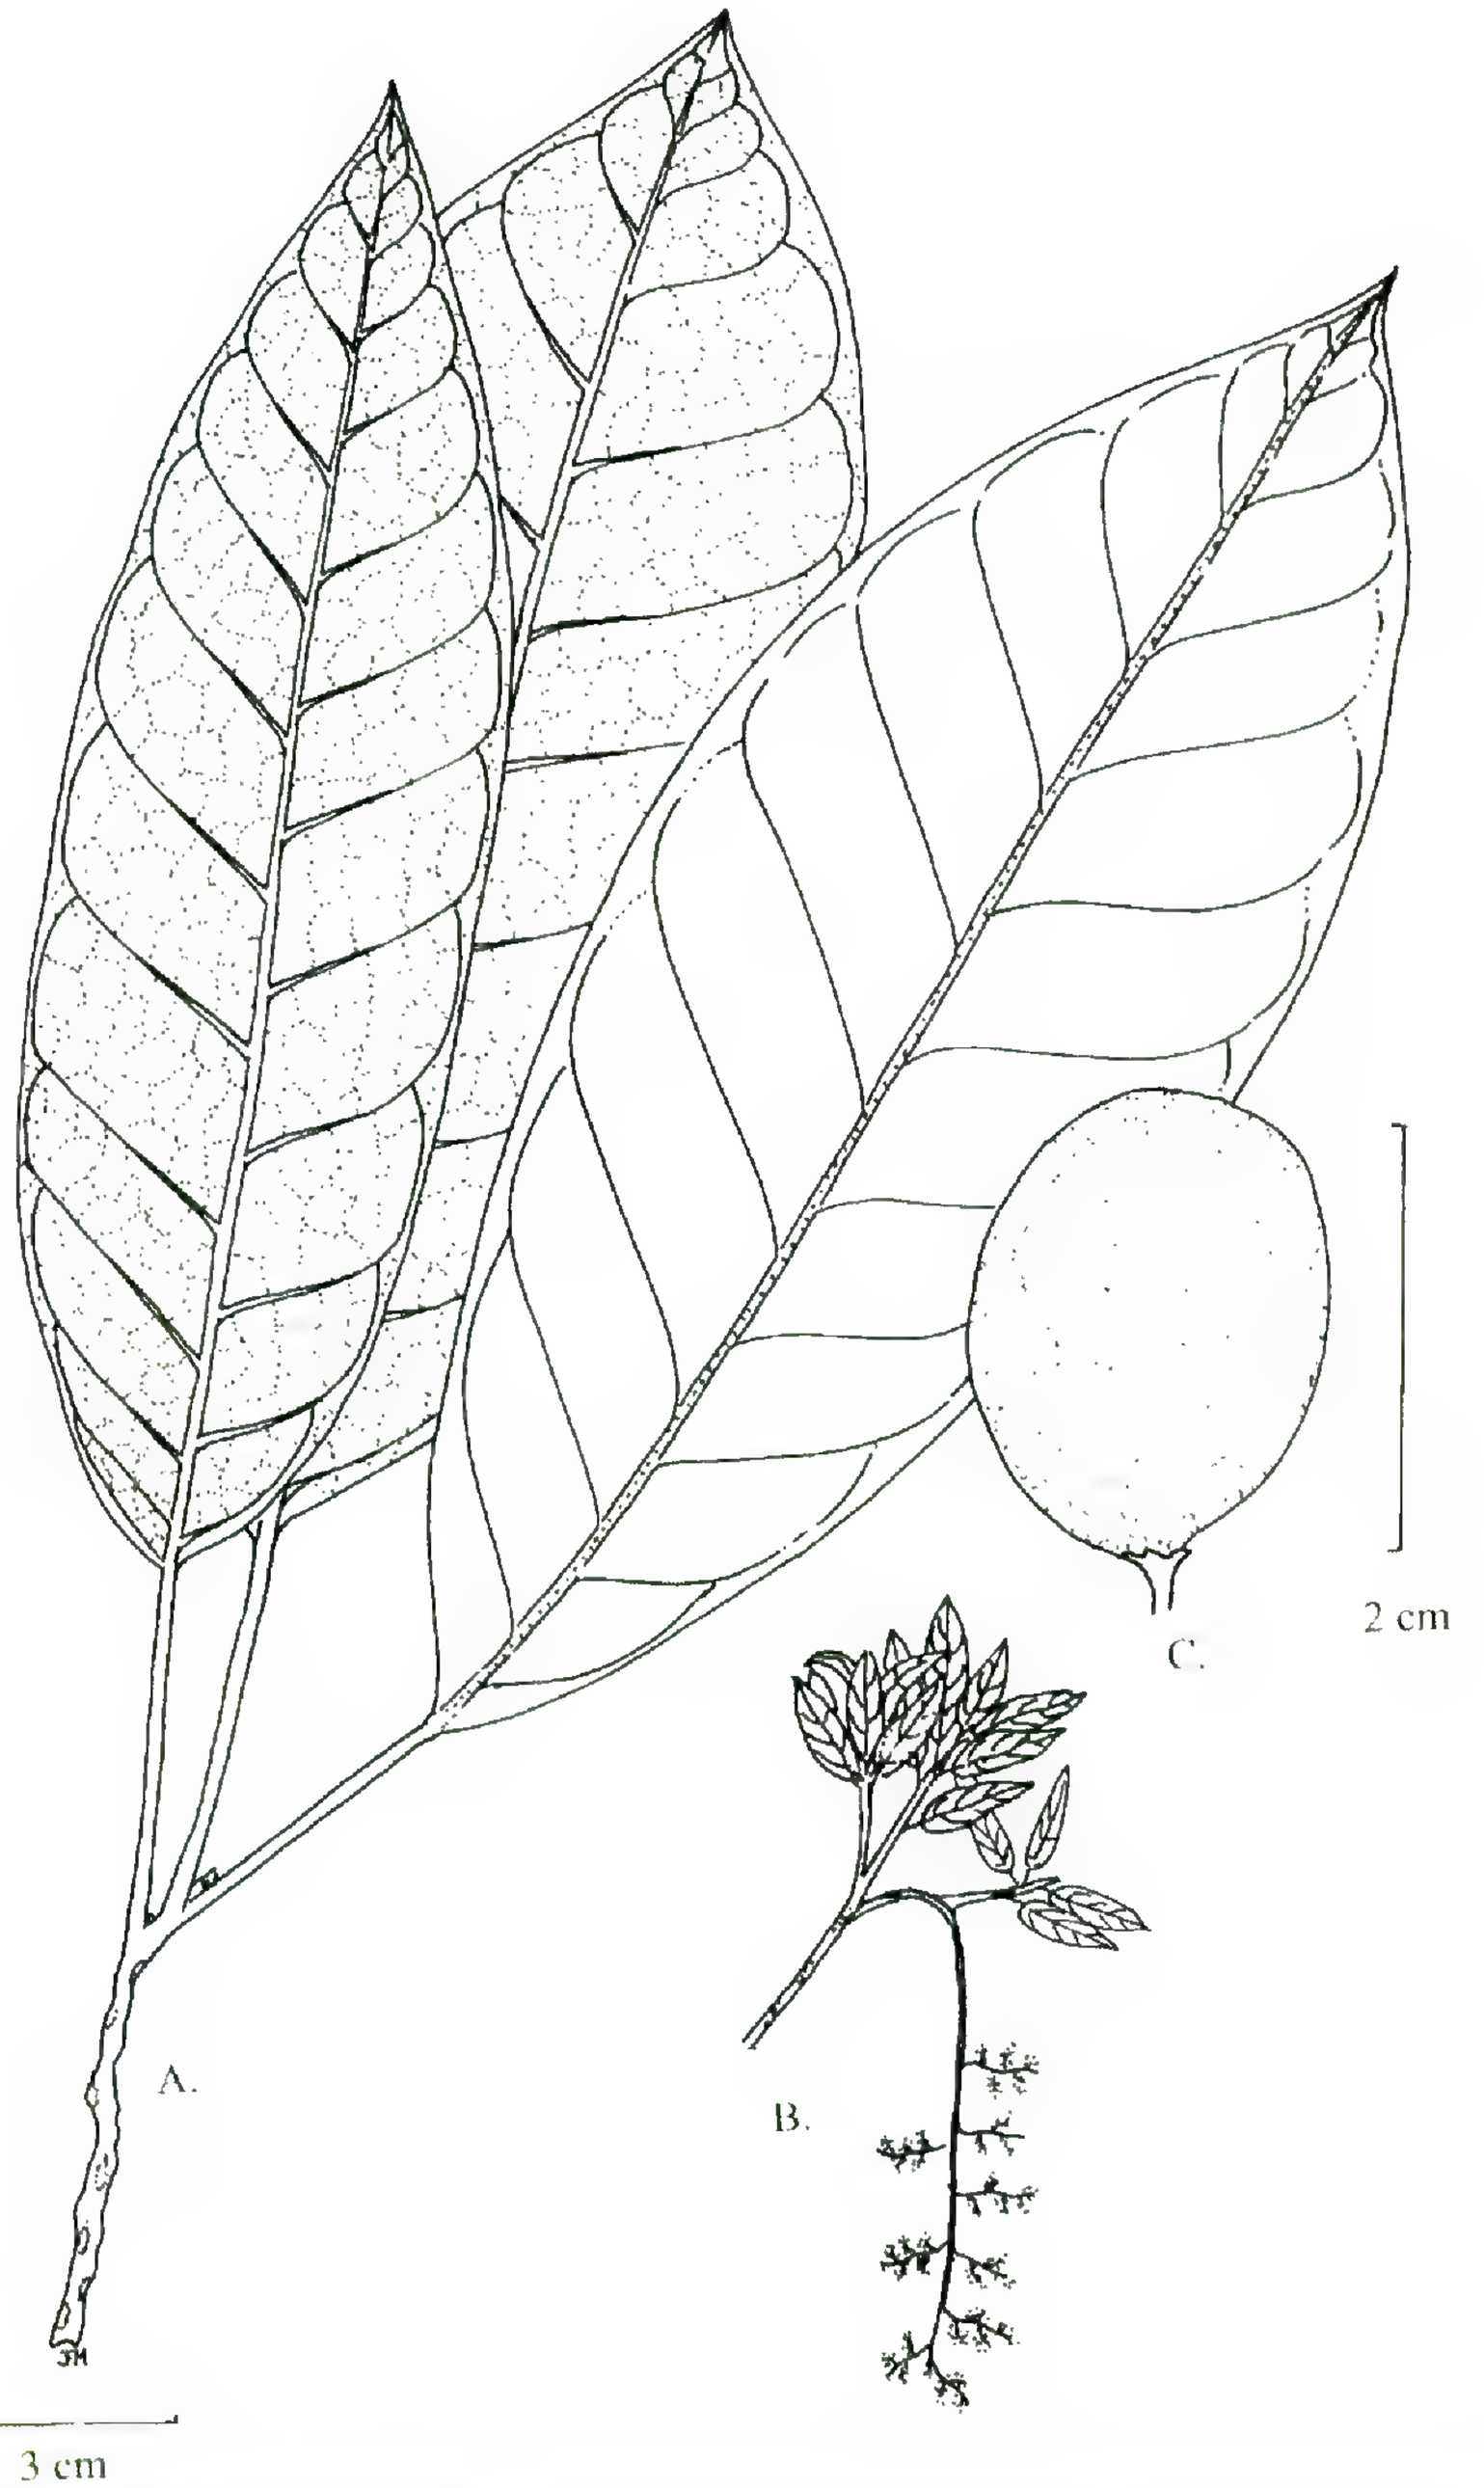

FIG. 3. *Meliosma depressiva* J.F. Morales (*Morales & Ulate 5379*, INB). **A.** Hábito. **B.** Inflorescencia. **C.** Frutos.

paniculadas, densamente puberulentas a tomentuloso-puberulentas, 20–75 cm largo; flores subsésiles y con pedicelos 0.5–1.5 mm; sépalos 5, ovados, anchamente agudos apicalmente, densamente puberulentos a tomentulos-puberulentos; pétalos rojo.vino a rojo-marrón, ca. 2 mm largo, anchamente ovados, glabros; ovario ca. 1 mm largo. Frutos 2.2–2.7 × 1.6–1.8 cm, subesférico.

Distribución.—Endémica a Costa Rica, donde se encuentra en la Cordillera Volcánica Central, Cordillera de Talamanca, Zona Protectora Cerros de Turrubares y en la Fila Aguabuena, en las vertiente pacífica, 1300–1900 m. Probablemente también en Panamá, en las provincias de Chiriquí y Bocas del Toro.

Fenología.—flores y frutos observadas de Enero a Setiembre, pero mayormente entre Abril y Agosto.

Meliosma depressiva puede distinguirse por sus hojas largamente pecioladas, inflorescencias usualmente muy largas y generalmente pendulosas, las cuales pueden alcanzar más de 75 cm de largo, con las flores rojo vino a rojo oscuro y distribución altitudinal sobre los 1300 m. Varias de las colecciones de *M. depressiva* se encuentran erróneamente identificadas como *M. vernicosa*, ya que ambas especies comparten características morfológicas similares, pero esta última se distingue por sus hojas con pecíolos más cortos, y con la lámina foliar glabra a glabrada. En Costa Rica y Panamá, *M. depressiva* es también similar a *M. allenii* (vease discusión previa).

En Mesoamérica, *M. depressiva* puede ser confundida con *M. grandifolia*, distribuida de México a Nicaragua (Matagalpa), pero esta última especie tiene la pubescencia de sus hojas conspicuamente hirsuta y erecta, no adpresa como en *M. depressiva*. En adición esta nueva especie se encuentra algo relacionada con *M. pittieriana*, distribuida en Colombia, Venezuela, Ecuador y Perú, pero sus láminas foliares son más angostas y sus flores son rosadas.

PARATIPOS. **COSTA RICA. Cartago:** near Río Naranjo, E of Cachí, 11 Jul 1971, *Lent 2002* (F, MO). **Heredia:** between Trinidad and Coliblanco, 25 Jul1975, *Utley & Utley 2718* (CR, F, MO [2 láminas]). **Puntarenas:** Buenos Aires, Parque Internacional La Amistad, Altamira, 6 Mar 1999, *Alfaro & Alfaro 2174* (CR, INB, MO); Buenos Aires, estación Altamira, 6 Dic 1999, *Alfaro 2604* (CR, INB, MO); Parque Internacional a Amistad, Cordillera de Talamanca, Pittier, 8 Jun 1995, *Angulo 329* (INB); foothills of the Cordillera de Talamanca, around Tres Colinas, 20 Mar 1984, *Davidse et al. 25672* (INB, MO); foothills of the Cordillera de Talamanca, between Agua Caliente and Río Canasta, 8 Set 1984, *Davidse et al. 28306* (CR, MO); around Río Canasta, between Cerro Frantzius and Cerro Pittier, 6 Set 1984, *Davidse et al. 28409* (MO); Parque La Amistad, Pittier, sendero a Río Gemelo, 30 Ene 1995, *Fletes 29* (INB, MO); La Amistad, sendero a Cerro Pittier, 15 Jun 1995, *Gamboa 252* (INB, MO); Zona Protectora Las Tablas, near Las Alturaas biological station, Ene 1996, *Holl 1131* (CR); Parque Internacional La Amistad, estación Pittier, 1 Ago 1995, *Moraga 266* (INB); Parque Internacional La Amistad, estación Altamira, Río Colorado, 9 Abr 1996, *Villalobos 301* (CR, INB, MO). **San José:** Pérez Zeledón, Santa Elena, 13 Set 1997, *Alfaro & Segura 1382* (INB, MO); Pérez Zeledón, Chumasquera, 16 Feb 2000, *Alfaro & Castro 2836* (INB, MO); Zona Protectora Cerros de Turrubares, faldas Cerro Turrúbares, 31 Mar 1990, *Zúñiga et al. 166* (CR, MO).

7. Meliosma donnellsmithii Urban, Bot. Gaz. 37:214. 1904. TIPO. COSTA RICA. CARTAGO: Río Turrialba, 500 m, Mar 1896 (fl), *Donnell Smith 6852* (HOLOTIPO: US; ISOTIPO: NY).

Distribución.—Nicaragua y Costa Rica, 0-750 m.

Fenología.—Floración de Abril a Julio.

Esta especie se reconoce fácilmente por el tamaño y forma de sus hojas, usualmente subsésiles o muy cortamente pecioladas (menos 12 mm). Anteriormente este nombre fue utilizado para dos especies diferentes, una de ellas previamente no descrita (vease discusión en *M. clandestina*).

8. Meliosma frondosa Cuatrecasas & Idrobo, Caldasia 7:193. 1955. TIPO. COLOMBIA. Cundinamarca: Zipacón, cabeceras del Río Apulo, entre la Hacienda Sebastopol y Dos Caminos, 1900–2100 m, 24 Dic 1953 (fl), *Idrobo & Hernández 1532* (HOLOTIPO: COL; ISOTIPOS: F, NY, US).

Distribución.—Panamá, Colombia, Ecuador, Venezuela, Perú y Bolivia, 1600-3100 m.

Fenología.—Floración entre Diciembre y Enero.

Esta especie se reconoce fácilmente por sus hojas conspicuamente bulladas y algunas veces revolutas marginalmente. La única especie con hojas conspicuamente bulladas y revolutas marginalmente en Mesoamérica es *M. linearifolia*, pero la forma de las láminas es totalmente diferente.

9. Meliosma glabrata (Liebmann) Urban, Ber. Deutsch. Bot. Ges. 13:212. 1895. *Lorenzanea glabrata* Liebm., Vidensk. Meddel. Dansk Naturhist. Foren. Kjobenhavn 1850: 71. 1850. Tipo. Costa Rica. Cartago: Turrialba, 1845 (fl), *Oersted s.n.* (HOLOTIPO: C; photograph Field negative 13373, INB).

Lorenzanea ira Liebm., Vidensk. Meddel. Dansk Naturhist. Foren. Kjobenhavn 1850:71. 1850. *Meliosma ira* (Liebm.) L.O. Williams, Fieldiana, Bot. 31:261-262. 1967. TIPO. COSTA RICA. ALAJUELA: Naranjo, May 1845 (fl), *Oersted s.n.* (HOLOTIPO: C, no examinado).

Meliosma tonduzii Donnell Smith, Bot. Gaz. 55:432. 1913. TIPO. COSTA RICA. CARTAGO: Tucurrique, 635-700 m, *Tonduz 13368* (HOLOTIPO: US; ISOTIPO: US).

Meliosma panamensis Standley, Trop. Woods. 10:49. 1927. TIPO. PANAMA. BOCAS DEL TORO: Almirante region, Changuinola valley, 1927 (fr), *Copper & Slater 29* (HOLOTIPO: US; ISOTIPOS: F, MO, NY).

Distribución.—México, Nicaragua, Costa Rica a Colombia, Ecuador y Perú, 500-1300 m.

Fenología.—floración Febrero a Junio.

Esta especie se reconoce fácilmente por tener inflorescencias mayormente cauliflоras. Aunque existen especímenes que pueden tener inflorescencias axilares, sus inflorescencias glabras o casi glabras las separan al instante de especies similares. Adicionalmente, puede confundirse con *M. occidentalis*, pero esta especie se reconoce por las láminas foliares usualmente pubescentes por el envés y las inflorescencias con flores muy laxamente distribuidas (vrs densamente aglomeradas en *M. glabrata*).

10. Meliosma grandiflora Morton ex A.H. Gentry, Ann. Missouri Bot. Gard. 67:957, fig. 1 C–D. 1980 [1981]. TIPO. COSTA RICA: vicinity of El General, 730 m, *Skutch 4049* (HOLOTIPO: MO; ISOTIPOS: CR, NY)

Distribución.—Costa Rica y Panamá, 0–1800 m.

Fenología.—flores observadas de Enero a Junio.

En Mesoamérica es la especie que tiene los pétalos más grandes. Se puede confundir con *Meliosma glabrata*, pero reconoce fácilmente por sus inflorescencias racemosas o espiciformes,con los ramos laterales conspicuos y por sus pétalos mucho más grandes.

11. Meliosma hartshornii A.H. Gentry, Ann. Missouri Bot. Gard. 73:820. 1986 [1987]. TIPO. COSTA RICA. HEREDIA: road to Volcán Barba, 2 km N of Sacramento, 2750 m, 29 Dic 1974 (fl), *Hartshorn 1608* (HOLOTIPO: MO; ISOTIPO: CR).

Distribución.—Costa Rica y Panamá, 2300–3000 m.

Fenología.—floración de Octubre a Marzo y Junio.

Restringida a las regiones más altas de la Cordilleras, esta especie se reconoce por sus hojas glabras a glabradas, con la lámina conspicuamente revoluta basalmente e inflorescencias claramente paniculadas, con las flores sésiles a subsésiles.

12. Meliosma idiopoda Blake, J. Wash. Acad. Sci. 14:289. 1924. TIPO. COSTA RICA. CARTAGO: Tucurrique, 635–700 m, *Tonduz 13372* (HOLOTIPO: US).

Meliosma dives Standley & Steyermark, Publ. Field Mus. Nat. Hist., Bot. Ser. 23:60-61. 1944. TIPO. GUATEMALA. SUCHITEPÉQUEZ: eastern slopes of Volcán de Santa Clara, above Chiracao, May 1942 (fl), *Steyermark 46773* (HOLOTIPO: F).

Distribución.—México a Panamá, (500–) 100–2000 m.

Fenología.—Especímenes con flores han sido recolectados de Noviembre a Abril.

Meliosma idiopoda es fácilmente reconocible por sus hojas cortamente pecioladas, esencialmente glabras, inflorescencias con flores conspicuamente pediceladas y frutos muy pequeños, menores a 1 cm de diámetro. Llega a ser localmente abundante en las regiones donde crece y es sumamente atractiva durante la floración, por las numerosas inflorescencias que produce y la coloración blanca de sus flores.

13. Meliosma linearifolia A. Gentry, Ann. Missouri Bot. Gard. 67:960, fig. 1 A–B. 1980 [1981]. TIPO. PANAMÁ. PANAMÁ: Localidad exacta preservada, 12 Mar 1969 (fl), *Correa & Dressler 1148* (HOLOTIPO: MO; ISOTIPO: NY).

Distribución.—Endémica a Panamá.

Fenología.—El único especímen conocido hasta el momento, fue recolectado con flores en Marzo.

Una de las especies más distintivas especies en el género que se reconoce al instante por sus hojas lineares y muy largas. Despúes de la colección tipo, esta especie ha sido raramente colectada y ha sido incluida en la lista roja de especies amenazadas de la Unión Internacional para la Conservación de la Naturaleza (Hilton-Taylor, 2000). Por lo tanto, su localidad específica se omite.

14. Meliosma occidentalis Cuatrecasas, Lloydia 11:217. 1948. TIPO. COLOMBIA. VALLE: Río Anchicayá, 230-260 m, sin fecha (fl), *Cuatrecasas 15279* (HOLOTIPO: F; ISOTIPOS: COL, US).

Distribución.—México (?), Costa Rica, Panamá, Colombia y Ecuador, 100–800 (–1200) m.

Fenología.—floración en Setiembre y Octubre.

Este nombre ha sido utilizado en forma común y errónea, para identificar

especímenes pertenecientes a *Meliosma vernicosa* y en algunos casos *M. glabrata*. Prefiero no utilizar los carácteres de venación pubescente empleados por Gentry (1980) y Durán (1997), ya que aunque es notable que esta especie tiene mayormente nervios y pecíolos diminutamente puberulentos, también he encontrado al menos 2 especímenes con hojas totalmente glabras. El carácter más distintivo para separarla de las especies relacionadas son las flores laxamente dispuestas de sus inflorescencias.

También puede ser confundida con *M. depressiva*, con quién comparte formas de hoja y pubescencia similares, sobretodo en especímenes con brotes muy jovenes de ramas, pero se reconoce por sus pecíolos más cortos, flores más grandes y distribución geográfica usualmente diferente.

Aunque he revisado bastante material de Costa Rica y Panamá, solamente he podido ubicar tres especímenes con flores que encajan con la descripción original; sin embargo, uno de ellos que difiere por sus hojas más pequeñas y totalmente glabras, este especímen de la Península de Osa es ubicado tentativamente bajo este nombre e incluso podría representar otra especie diferente de Suramérica. Mucho otro material presente en herbarios e identificado con este nombre está estéril y no se puede tener certeza sobre su identificación.

Especímenes representativos examinados. **COSTA RICA. Heredia:** Cerros Sardinal, N of Chilamate, 10 Jul 1982 (fl), *Hammel & Trainer 13119* (DUKE, INB). **Limón:** Braulio Carrillo National Park, path beyond Río Sucio, May 1984, *Gómez et al. 22799* (CR, INB, MO). **Puntarenas:** Reserva Forestal Golfo Dulce, Playa Campanario, Sierpe, 12 Oct 1991, *Harmon 273* (INB).

15. Meliosma schlimii (Turcz.) Triana, Ann. Sci. Nat., Bot., ser. 5, 16:363. 1872.

Oligostemom schlimii Turcz., Bull. Soc. Imp. Naturalistes Moscou 31: 447. 1858. TIPO. Colombia. Santander del Norte: localidad perdida, *Schlim 702* (HOLOTIPO: G-DC, fotografía negativo Field 23600, INB).

Distribución.—Costa Rica a Colombia y Ecuador, 0–750 m.

Fenología.—Especímenes con flores han sido recolectados en Junio y Julio.

Se reconoce por la dimensión de sus hojas, densamente ferrugíneas a marrón puberulentas en el envés, subsésiles y atenuadas basalmente. En Mesoamérica, no esta relacionada cercanamente con ninguna otra especie.

16. Meliosma subcordata Standley, Publ. Field Mus. Nat. Hist., Bot. Ser. 18:649. 1937. TIPO. COSTA RICA. ALAJUELA: La Palma de San Ramón, 26 Oct 1922 (fl), *Brenes 3781* (HOLOTIPO: F; ISOTIPO: NY).

Distribución.—Endémica a Costa Rica, donde se encuentra restringida a la Cordillera de Tilarán, 1400–1600 m.

Fenología.—Floración Junio a Agosto.

No es una especie muy común en el campo, pero se reconoce al instante por sus hojas cortamente pecioladas, con la lámina densamente puberulenta en el envés y levemente cordadas basalmente. Aunque se podría considerar como

una variedad morfológica de *M. brenesii*, no se han encontrado variaciones morfológicas y traslapes entre los caracteres claves en las diferentes poblaciones examinadas en el campo que así lo sugieran.

18. Meliosma vernicosa (Liebm.) Griseb., Cat. Pl. Cub. 47.1866. *Lorenzanea vernicosa* Liebm., Vidensk. Meddel. Dansk Naturhist. Foren. Kjobenhavn 1850:72. 1850. TIPO. COSTA RICA. ALAJUELA: Naranjo, fecha perdida (fl), *Oersted s.n.* (HOLOTIPO: C; fotografía negativo Field 13379, INB).

Distribución.—Nicaragua, Costa Rica & Panamá, 1100-2300 m.

Fenología.—Flores observadas entre Junio y Julio.

Meliosma vernicosa ha sido comúnmente confundida con *M. depressiva*, pero se distingue por varios carácteres. En primer lugar, esta especie tiene hojas con pecíolos menos de 3.5 cm largo, en contraposición de *M. depressiva*, que tiene pecíolos usualmente más de 4.5 cm largo. La pubescencia de las hojas es también diferente siendo las hojas de *M. vernicosa* glabras a glabradas. Usualmente tiene inflorescencias más compactas, con flores cremas a blancas. Es importante aclarar para futuros monografiadores, que aunque la localidad del especimen tipo exacta es desconocida, este fue probablemente recolectada por Oersted en las faldas del Volcán Barva, en la Cordillera Volcánica Central, donde realizó varias colecciones. En esta zona, *M. vernicosa* es localmente abundante.

AGRADECIMIENTOS

Deseo agradecer a los curadores y directores de COL, CR, F, HUA, JAUM, K, MEDEL, MO, NY, USJ por el préstamo y uso de colecciones. Asimismo, deseo dar las gracias al personal del Herbario de la Universidad de Antioquia (HUA) y del Herbario de la Fundación Jardín Botánico Javier Antonio Uribe (JAUM), Colombia, por las facilidades logísticas brindadas durante mis visitas a Medellín. Esta publicación fue financiada por la Asistencia Holandesa para el Desarrollo (NEDA) a través del proyecto "Desarrollo del Conocimiento de la Biodiversidad y Uso Sostenible en Costa Rica" conducido por el Instituto Nacional de Biodiversidad (INBio). Además, la investigación fue posible además gracias al convenio de cooperación entre el Ministerio de Ambiente y Energía (MINAE) e INBio con el fin de completar en Inventario Nacional de Biodiversidad.

BOOK NOTICES

MARK BLUMENTHAL. 2003. **The ABC Clinical Guide to Herbs.** (ISBN 1-58890-157-2 hdk.). Thieme New York, 333 Seventh Avenue, New York, NY 10001, U.S.A. (Orders: customerservice@theime.com, 800-782-3488, 212-760-0888). $49.95, 480 pp, 58 b/w photos, 29 b/w line drawings, 8 1/2" × 11 1/2".

This book must be the ultimate resource for information about each of the twenty-nine most frequently used herbs as judged by retail sales. It offers a detached review of the data of specific products which have been the subject of clinical studies.

There are two pages of clinical overviews, a patient information sheet, and a comprehensive monograph on each herb as well as two photographs and a line drawing. The primary and potential uses, pharmacological actions, dosage and administration, adverse effects and the regulatory status in various countries around the world are spelled out plainly for each herb. In addition, abundant references are included.

This should be a valuable book for the lay person as well as the clinician at a time when alternative medicines are being widely discussed.—*Ruth Ginsburg, Botanical Research Institute of Texas, Fort Worth, TX, U.S.A.*

GORDON R. HANKS (Editor). 2002. **Narcissus and Daffodil: The Genus *Narcissus*.** (ISBN 0-415-27344-7, hdk.). Taylor & Francis, 11 New Fetter Lane, London EC4P 4EE, UK and 29 West 35th Street, New York, NY 10001, U.S.A. (Orders: info@tandf.co.uk, www.tandf.co.uk, 44 (0) 207 583 9855, fax 44 (0) 207-842-2298, standing orders call 44 (0)1264 343071). £70 (±$120.00), 452 pp, 16 color photos, 13 b/w photos, 98 b/w drawings, 31 tables, 7" × 9 3/4".

This is volume 21 of the Medicinal and Aromatic Plants—Industrial Profiles, a series aimed at those engaged in research in botany, agriculture, pharmacognosy, phytochemistry, the food flavor, cosmetic and fragrance industries, alternative medicine and in other pharmaceutical and health sciences. "Narcissus and Daffodil is the first book to provide a complete overview of the genus Narcissus." There are 19 chapters presenting original research material and information. Each chapter is complete with references; some 1,700 references are scattered throughout the book.

ABSTRACT

Packera texensis, sp. nov., is described and illustrated. It is endemic to the granitic sands of the Central Mineral Region within the Edwards Plateau of central Texas where it is known from four counties.

RESUMEN

Se describe y se ilustra ***Packera texensis***, sp. nov. Es endémica de las arenas graníticas de la "Central Mineral Region" en la Meseta Edwards del centro de Texas, de donde se conoce en cuatro condados.

INTRODUCTION

Packera is a genus of 63 species that occur almost exclusively in North America and that have been treated historically as the "Aureoid" complex of the genus *Senecio*. Löve and Löve (1976) pointed out that this anomalous group of species has a chromosome base number of x = 22 or x = 23, unlike other members of *Senecio* which are characterized by having a number of x = 10. They proposed that Barkley's "Aureoid Senecios" be placed in a new genus, *Packera*, based primarily on gross morphology and chromosome number. The group has notably imprecise species boundaries and a complex taxonomic history (Bain 1988; Barkley 1962, 1963, 1968a, 1968b, 1978, 1980, 1988; Freeman & Barkley 1995; Kowal 1975; Packer 1972). During field work in central Texas, a species of *Packera* has been discovered that is distinct from others currently known.

DESCRIPTION

Packera texensis R.J. O'Kennon & D.K. Trock, sp. nov. (**Fig. 1**). TYPE: U.S.A. TEXAS. GILLESPIE CO.: Keese Road, 0.7 mi (11 km) N of Keese Sagebeil Road, ca. 18 mi (29 km) N of Fredericksburg, in soils derived from weathered granite and among granite boulders, 1720 ft (524 m), 5 Mar 2000, *R.J. O'Kennon & D.K. Trock 11059* (HOLOTYPE: BRIT; ISOTYPES: MEX, MSC, NY, TAES).

Propter laminas 1.5–4 cm latas lobis terminalibus grandibus, denique petiolos distinguibiles a *P. plattensis* arcte similans, sed am ca laminarum lateralibus irregularibus (non dentatis vel laceratis), caudice usque ad 5 mm (non 1–1.2) cm diametre, flosculis radii 13 (non 8), nec non habitu pereni (non bieni) prae clare distat.

Robust herbaceous perennial, arising from an erect woody taproot-like caudex 6–12 mm thick, glabrous to sparingly floccose about nodes and among heads of

FIG. 1. Habit and floral details of *Packera texensis* (from holotype, BRIT).

capitulescence. Stems 2–4(–5) dm, single or 2–5, rarely in clusters of up to 20. Basal leaves petiolate, blades elliptic-ovate, broadly oblanceolate or lyrate, bases tapering, margins irregularly and deeply parted to irregularly lobed with 3–9 lobes on each side and again incised at apex, 4–7 cm long and 1.5–2.5 cm wide, usually about 2 times longer than wide, the petiole subequal to the blade; cauline leaves gradually or sometimes abruptly reduced distally, similar in aspect to the basal leaves. Capitulescence an open or congested corymbiform cyme of 4–20(–30) heads. Capitula campanulate; phyllaries 13 or 21, 5–7 mm long. Ray florets conspicuous, golden-yellow, ca. 13 in number, ligule 7–9(–10) mm long. Cypselae, 2.5–3.0 mm long, 0.5 mm wide, with thick appressed simple trichomes along the angles, pappi 5–7 mm long.

Habitat and Phenology.—Gillespie County lies on the northern boundary of the Balcones Canyonlands Association, an area of limestone plateaus deeply dissected by creeks and rivers on the Edwards Plateau. The county is on the southern boundary of the Llano Uplift or Central Mineral Region, where the soil is primarily made up of granite, sandstone, gneiss, schist, and granitic-derived sands. The Edwards Plateau is botanically well known and has long been recognized as a region of endemism (Correll & Johnston 1979).

Recent collections of *Packera texensis* were made in an area of dry granitic gruss near the boundary of Gillespie and Llano counties. The plants are site specific and relatively uncommon, and the species is currently known from only a few localities. *Packera texensis* arises quickly from evergreen winter rosettes during the January rains and blooms as early as the first week in February. Plants begin to senesce by the end of March during a rapid drying out of the substrate prior to the spring rainy season that beings in late April.

Additional collections examined: U.S.A. **TEXAS. Callahan Co.:** I-20 (old Rt. 80) frontage road N side, 1 km E of County Road CR 115, 15 Apr 2002, *R.J. O'Kennon 16020* (BRIT); 3 mi S of Eula along Hwy 603, 20 Mar 1963, *N.C. Henderson 63-45* (BRIT); 2 mi E of Clyde along Hwy 80, sandy roadside, 8 Apr 1962, *N.C. Henderson 62-67* (BRIT). **Gillespie Co.:** 3.5 mi N of Eckert on Hwy 16, 17 Mar 1964, *D.S. Correll 29037* (BRIT); Keese Road, 0.7 mi (11 km) N of Keese-Sagebeil Road, ca. 18 mi (29 km) N of Fredericksburg, decaying granitic gruss soils among granite boulders, 1720 ft (524 m), 20 Mar 1990, *R.J. O'Kennon 6577* (BRIT); 26 Feb 1991, *R.J. O'Kennon 8373* (BRIT); old Llano Road N of Fredericksburg, 21 Feb 1931, *E. Whitehouse 12050* (BRIT). **Llano Co.:** Enchanted Rock, granitic soil, partial shade, 18 Apr 1931, *E. Whitehouse 12054* (BRIT). **Mason Co.:** 1 mi S of Katemcy, granite outcrop, 5 Apr 1984, *S. Pence 82* (BRIT).

DISCUSSION

Packera texensis most closely resembles *P. tridenticulata* (Rydb.) W.A. Weber & A. Löve but it shares characteristics of *P. tampicana* (DC) C. Jeffrey as well as *P. plattensis* (Nutt.) W.A. Weber & Löve. Most specimens would key to *Senecio tridenticulata* (Rydb.) in Correll and Johnston's *Manual of the Vascular Plants of Texas* (1979). Some of the more pubescent specimens would key to *Senecio plattensis* (Nutt.).

Morphologically the new species differs from *P. tridenticulata* mainly in height, shape and size of leaves, leaf margins, ratio of petiole length to blade length, length of phyllaries, length and pubescence of achenes. It differs from *P. plattensis* in number of stems, type of perennating structures, amount of location of pubescence, number of ray florets, length of ligules, length and pubescence of achenes. It differs from *P. tampicana* in duration, number of stems, pubescence, overall leaf shape and degree of lobing of the margins, and number of ray florets. Characters useful in recognizing these species are listed in Table 1. Data in this table were obtained by the senior author from measurements made on dozens of herbarium specimens.

There are three other species of *Packera* in Texas, *P. glabella*, *P. obovata* and *P. tomentosa*. There is little likelihood that any of these species could be mistaken for *P. texensis*. *Packera glabella* has distinctly striated hollow stems, a short fibrous-rooted caudex, and leaves with margins pinnately lobed. *Packera ovobata* has abundant stolens, a rhizomatous caudex, and distinctly obovate leaves and *P. tomentosa* has persistent floccose pubescence covering all of the vegetative surfaces. In contrast to these three species *P. texensis* lacks the hollow striated stems, has a distinctly tap-rooted caudex, no stolons, leaves that are elliptic-ovate to oblanceolate with margins that are at most irregularly lobed and pubescence restricted to the leaf axils, lower petioles and inflorescence.

There are habitat and substrate preferences that may also be used to distinguish these four species. *Packera texensis* has been collected only on or near the Edwards Plateau in soils derived from igneous or metamorphosed igneous rocks such as granite, gneiss and schists. *Packera plattensis* has been collected from a wide variety of soil types, but is most abundant in the limestone and sandstone-derived soils of the Great Plains. *Packera tridenticulata* is a plant of the High Plains and foothills of the Rocky Mountains, while *P. tampicana* is always found in disturbed wet sandy or muddy sites. Distribution maps for the four species are provided in Figure 2.

Hybridization is apparently common in this genus, but there is no evidence that *P. texensis* hybridizes with any of its congeners. It is consistently distinct in morphology, habitat and substrate preference, and flowering phenologies. There is also good distributional data to support the recognition of the new species. Additional field and laboratory studies will undoubtedly contribute to our understanding of the relationship of *P. texensis* to other morphologically similar species.

KEY TO *PACKERA TEXENSIS* AND ITS IMMEDIATE ALLIES

1. Plants permanently floccose-tomentose at the base of the stem and in the axils of the leaves, lightly tomentose elsewhere _____ **P. plattensis**
1. Plants with light tomentum at the base of the stem and in leaf axils, glabrous elsewhere.

TABLE 1. Comparison of *Packera texensis* with selected congeners.

	P. texensis	**P. tridenticulata**	**P. plattensis**	**P. tampicana**
Duration and habit	Perennial, woody caudex, 4–12 mm thick, no stolons	Perennial, caudex, 2–4 mm thick, terminally branching taproot,	Biennial or perennial from erect or suberect caudex, may be stoloniferous	Annual from a slender taproot
Height	3–4(–5) dm	1–3(–4) dm	2–6(–7) dm	2–5(–6) dm
Number of stems	Single to several	Single to several	Usually single, rarely 2–3	Usually single, or rarely 2–6 clustered
Pubescence	Glabrous to lightly floccose near nodes and among capitula	Glabrous to lightly floccose near nodes	Floccose-tomentose at base of stem, in nodes, abaxial leaf surface and among capitula	Glabrous throughout
Leaf dimensions	Blades 4–8(–10) cm long, 1.5–2.5 cm wide	Blades 2–4(–5) cm long, 0.5–1.5 cm wide	Blades 2–7(–8) cm long, 1–3(–4) cm wide	Blades 4–12 cm long, 1–3(–4) cm wide
Petiole to blade ratio	Petioles subequal to blade	1–2 times longer than blade	1–1.5 times longer than blade	Petioles subequal to blade
Leaf blade shape	Elliptic-ovate to broadly oblanceolate	Lanceolate to narrowly oblanceoate	Elliptic-ovate to oblanceolate or rarely suborbicular	Oblanceolate to spatulate
Leaf margins	Irregularly incised or dissected to deeply parted or pinnatisect, occasionally lateral margins irregularly lobed	Entire, subentire or dentate near the apex, rarely sub-pinnatisect	Subentire to crenate, serrate-dentate or sublyrate	Deeply pinnate, 1–6 pairs of lateral lobes, large terminal lobes
Capitulescence	4–20(–30) capitula	4–12(–20) capitula	6–15(–20) capitula	4–15(–20) capitula
Phyllaries	13 or 21, 5–7 mm long, green, glabrous	13 or 21, 6–10 mm, green, sparsely tomentose proximally	13 or 21, 5–6 mm, green, densely tomentose proximally	13 or 21, 3–7 mm, green with reddish apices, glabrous
Ray florets	About 13	8–10, rarely 13	About 8	8 or 13
Ligule length	5–6(–7) mm	5–8(–9) mm	9–10(–11) mm	3–7 mm
Cypselae	1–1.5 mm long, thick appressed trichomes on the angles	1.5–2.5 mm long, glabrous or lightly hirtellous on the angles	1.5–2.5 mm, hirtellous on the angles or rarely glabrous	1–1.5 mm long, hirtellous on the angles

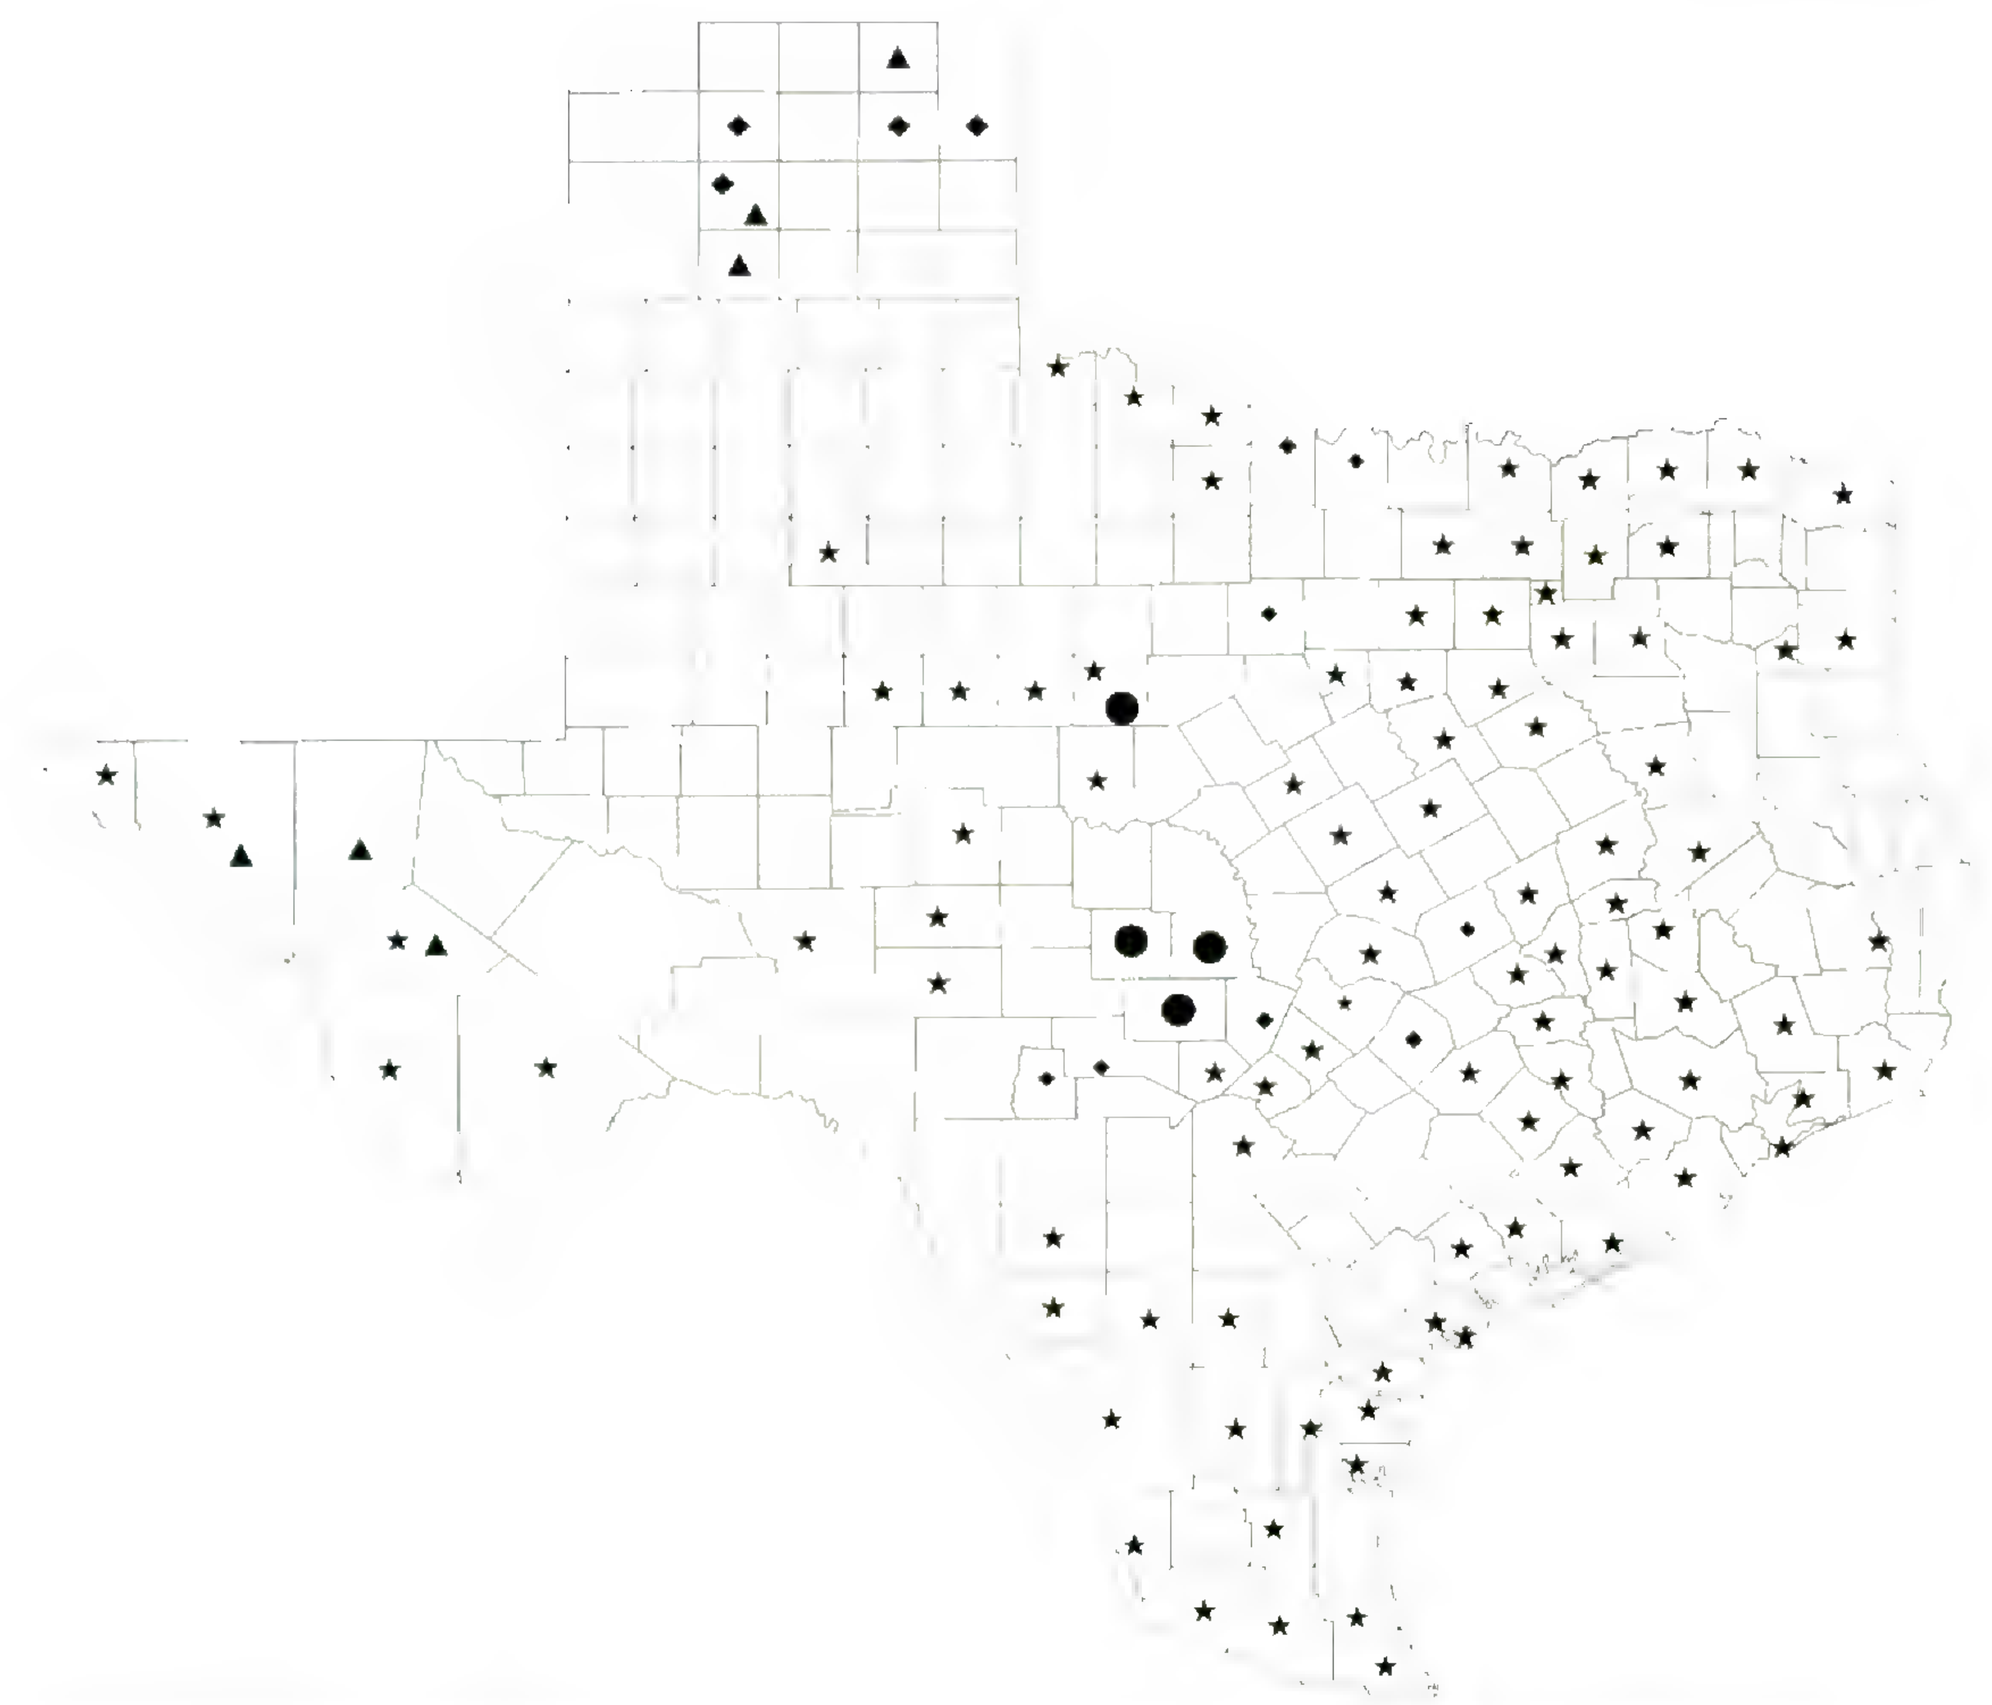

Fig. 2. Geographic distribution of four morphologically similar species of *Packera* in Texas. Circles = *P. texensis*; triangles = *P. tridenticulata*; diamonds = *P. plattensis*; stars = *P. tampicana*. Distributions are based on examination of over 300 herbarium specimens.

2. Basal leaves lanceolate or narrowly oblanceolate, margins entire, subentire to dentate near the apex or occasionally sub-pinnatisect _____ **P. tridenticulata**
2. Basal leaves elliptic-ovate, obovate or lyrate, margins lobed, parted or deeply incised.
   3. Annual, from a slender taproot _____ **P. tampicana**
   3. Perennial, from a stout, woody tap rooted caudex _____ **P. texensis**

ACKNOWLEDGMENTS

The authors would like to acknowledge Ted Barkley and Alan Prather for their assistance with various drafts of this manuscript. Also thanks to Guy Nesom and John Bain for providing their insightful comments. Special thanks go to Linny Heagy for her wonderful illustrations and to John Pipoly for providing the Latin diagnosis. We would also like to thank the following herbaria and their curators for the loan of specimens: BRIT, BRY, KANU, KSC, LSU, MICH, MO, MONT, MSC, MU, NDA, NLU, OSC, RSA, TEX, UC, UNM, VDB

BOOK NOTICES

JOHN J.W. COPEN (Editor). 2002. **Eucalyptus: The Genus *Eucalyptus*.** (ISBN 0-415-27879-1, hdk.). Taylor & Francis, 11 New Fetter Lane, London EC4P 4EE, UK and 29 West 35th Street, New York, NY 10001, U.S.A. (Orders: info@tandf.co.uk, www.tandf.co.uk, 44 (0) 207 583 9855, fax 44 (0) 207-842-2298, standing orders call 44 (0)1264 343071). £55 (±$70.00), 496 pp., 6 b/w photos, 60 b/w drawings, 45 tables, 7" × 9 3/4".

This is volume 22 of the Medicinal and Aromatic Plants—Industrial Profiles, a series aimed at those engaged in research in botany, agriculture, pharmacognosy, phytochemistry, the food flavor, cosmetic and fragrance industries, alternative medicine and in other pharmaceutical and health sciences. *Eucalyptus* is a genus of over 800 species. Seventeen chapters provide in-depth coverage from general aspects to cultivation to commercial distillation. "Chapters on botany, environmental and ecological aspects, cultivation, genetic improvement, chemistry, bioactivity, oil distillation, formulations and legislation, and international trade and markets, re complemented by appendices which provide further practical help and advice." As the publisher suggests, the book will surely be a valuable source of information on *Eucalyptus* for researchers in academia and industry alike.

SARA OLDFIELD. 2003. **Rainforests.** (ISBN 0-262-15106-5 hbk.). The MIT Press, 5 Cambridge Center, Cambridge, MA 02142-1493, U.S.A. (Orders: http://mitpress.mit.order, mitpress-order@mit.edu, 1-800-405-1619). $29.95, 159 pp., 200 color photos, 1 map, 9 1/2" × 12 1/2".

This extremely informative and well-organized book deals with the major rainforest regions of the world - both tropical and temperate. The author describes the habitat, flora and fauna, and indigenous people of each unique location and explains the various threats to its survival. If the writing is a little pedestrian, the message is clear: the ecosystems of the rainforest are very fragile and in great danger.

The photographs, from the Bruce Coleman Collection are brilliant in conveying the beauty and wonderousess of each region and its denizens. They could stand on their own as a picture book. But with the text the book makes the most compelling case for the conservation of the rainforest and the preservation of the delicate balance between man and nature A list of membership and governmental organizations involved with rainforests is included in the book as well as a bibliography for more information. Royalties from Rainforest will go to the Global Trees Campaign of Flora and Fauna International (FFI) and the United Nations Environmental Program to save the world's most threatened trees.—*Ruth Ginsburg, Botanical Research Institute of Texas, Fort Worth, TX, U.S.A.*

STUDIES IN *GLANDULARIA* (VERBENACEAE): THE *GLANDULARIA QUADRANGULATA* COMPLEX

James Henrickson

Department of Biological Sciences
California State University
Los Angeles, CA 90032, U.S.A.

ABSTRACT

This paper responds to Turner's inclusion of *Glandularia verecunda* and *G. racemosa* into *G. quadrangulata*. The latter has distinctive terminal appendages on the nutlets and the pericarp flares outward at the base; *G. verecunda*, is very similar vegetatively, has similar nutlets, but they lack the distinctive terminal appendage. Pollen/ovule ratios indicate that both taxa are facultative autogamous and both taxa have distinct ranges with limited areas of sympatry. No intermediates are known, and intermediate characteristics may not exist. They also differ in their flavonoid compliments supporting their recognition as distinct species. *Glandularia racemosa*, with larger corollas, a different nutlet type, and leaf structure, is a hexaploid (not tetraploid as in the other taxa) and represents a separate group within the genus and should not have been submerged into *G. quadrangulata*.

RESUMEN

Este artículo responde a la inclusión de Turner de *Glandularia verecunda* y *G. racemosa* en *G. quadrangulata*. Esta última tiene apéndices terminales distintivos en las núculas y el pericarpo se acampana hacia el exterior en la base; *G. verecunda*, es muy similar vegetativamente, tiene núculas similares, pero le falta el apéndice terminal distintivo. La relación polen/óvulos indica que ambos taxa son autógamos facultativos y ambos taxa tienen diferente distribución con áreas de simpatría limitada. No se conocen intermedios, y los caracteres intermedios puede que no existan. También se diferencian en su dotación de flavonoides que apoyan su reconocimiento como especies distintas. *Glandularia racemosa*, con corolas más grandes, un tipo diferente de núcula, y estructura de la hoja, es un hexaploide (no tetraploide como en los otros taxa) y representa un grupo separado en el género y no debería haber sido incluida en *G. quadrangulata*.

INTRODUCTION

Turner (1998) presented a new classification *Glandularia quadrangulata* (Heller) Umber submerging both *G. verecunda* Umber and *G. racemosa* (Eggert) Umber into *G. quadrangulata*. All three taxa are similar vegetatively. They are low-growing, branched, hairy, usually perennial herbs with broad, distally dissected leaves and have small, inconspicuous flowers with corolla limbs only 2.5–9 mm wide. Turner (1998) however, failed to take into consideration basic differences in nutlet structure, ploidy levels, and breeding systems of these taxa that support a different classification.

MATERIALS AND METHODS

The data presented here are based on empirical observations on specimens from the TEX-LL, SRSC herbaria. Direct counts of pollen grains were made from

unopened buds that were softened by boiling; the four anthers were opened directly on microscope slide.

RESULTS AND DISCUSSION

Nutlet structure.—Nutlets of *G. quadrangulata* are the most distinctive (Fig. 1 D). The nutlets are 3.3–4.2 mm long, the central bodies are slender, 0.55–0.65 mm wide, at the base and the outer pericarp wall greatly expands and flares outward to 1.2–1.6 mm in width. At the inner tip they have a large, thin, somewhat concave, ovate appendage 1.0–1.3 mm long. The inner or commissural surface of the nutlet is cream-white and covered with distinct papillate-aculeate excrescences. The commissural surface is nearly as wide as the nutlet in the central portion and extends to the top of the ovate appendage. The outer pericarp walls, as in most glandularias, are black, with a broad reticulate, raised pattern that extends from the tip about half way down the nutlets where it disorganizes into a series of vertical striae that extend to the nutlet base. The quartet of nutlets are so arranged that the flared bases expand over the receptacle and the distal appendages form a valvate dome over the developing nutlets through which the style extends from the tip of the united appendages. When the nutlets separate, they leave no distinctive receptacular rim.

The fruits of *Glandularia verecunda* are similar to those of *G. quadrangulata* except they lack the conspicuous terminal appendage (Fig. 1 H). They are (2.6–)2.8–3.2(–3.3) mm long, and the central body is also slender, 0.5–0.65 mm wide. The outer pericarp also abruptly flares out at the base to a width of 1.0–1.3 mm although this characteristic is not present in immature fruit. Again the inner whitish commissural face is nearly as wide as the central nutlet itself. The aculeate surface continues to the distal portion of the nutlet where its distal margin is rather truncated, sometimes retuse, marked by small horizontal beak that extends inward. The horizontal beak may be homologous to the much-expanded vertical beak in *G. quadrangulata*. In their broadly flared base and slender body, the broad commissural face of the nutlets are identical to those of *G. quadrangulata*.

Nutlets with similar slender bodies and greatly expanded bases occur in a small group of North American *Glandularia*, namely *G. polyantha* Umber, *G. delticola* (Small) Umber, and in two other taxa that also have greatly expanded air spaces in the adaxial portion of the nutlet: *G. tumidula* (Perry) Umber, and *G. brachyrhynchos* Nesom & Vorobik. Of note, the distinctive nutlet appendage is not unique to *G. quadrangulata* as it also occurs in species of southern South America (Uruguay, Brazil and Argentina) where *Glandularia tenera* (Spreng) Cabrera has an appendage similar to that of *G. quadrangulata* and *G. pulchella* (Sweet) Tronc. has a shorter, less-developed appendage. *Glandularia pulchella* is adventive in the United States from Florida into Texas and in northeastern

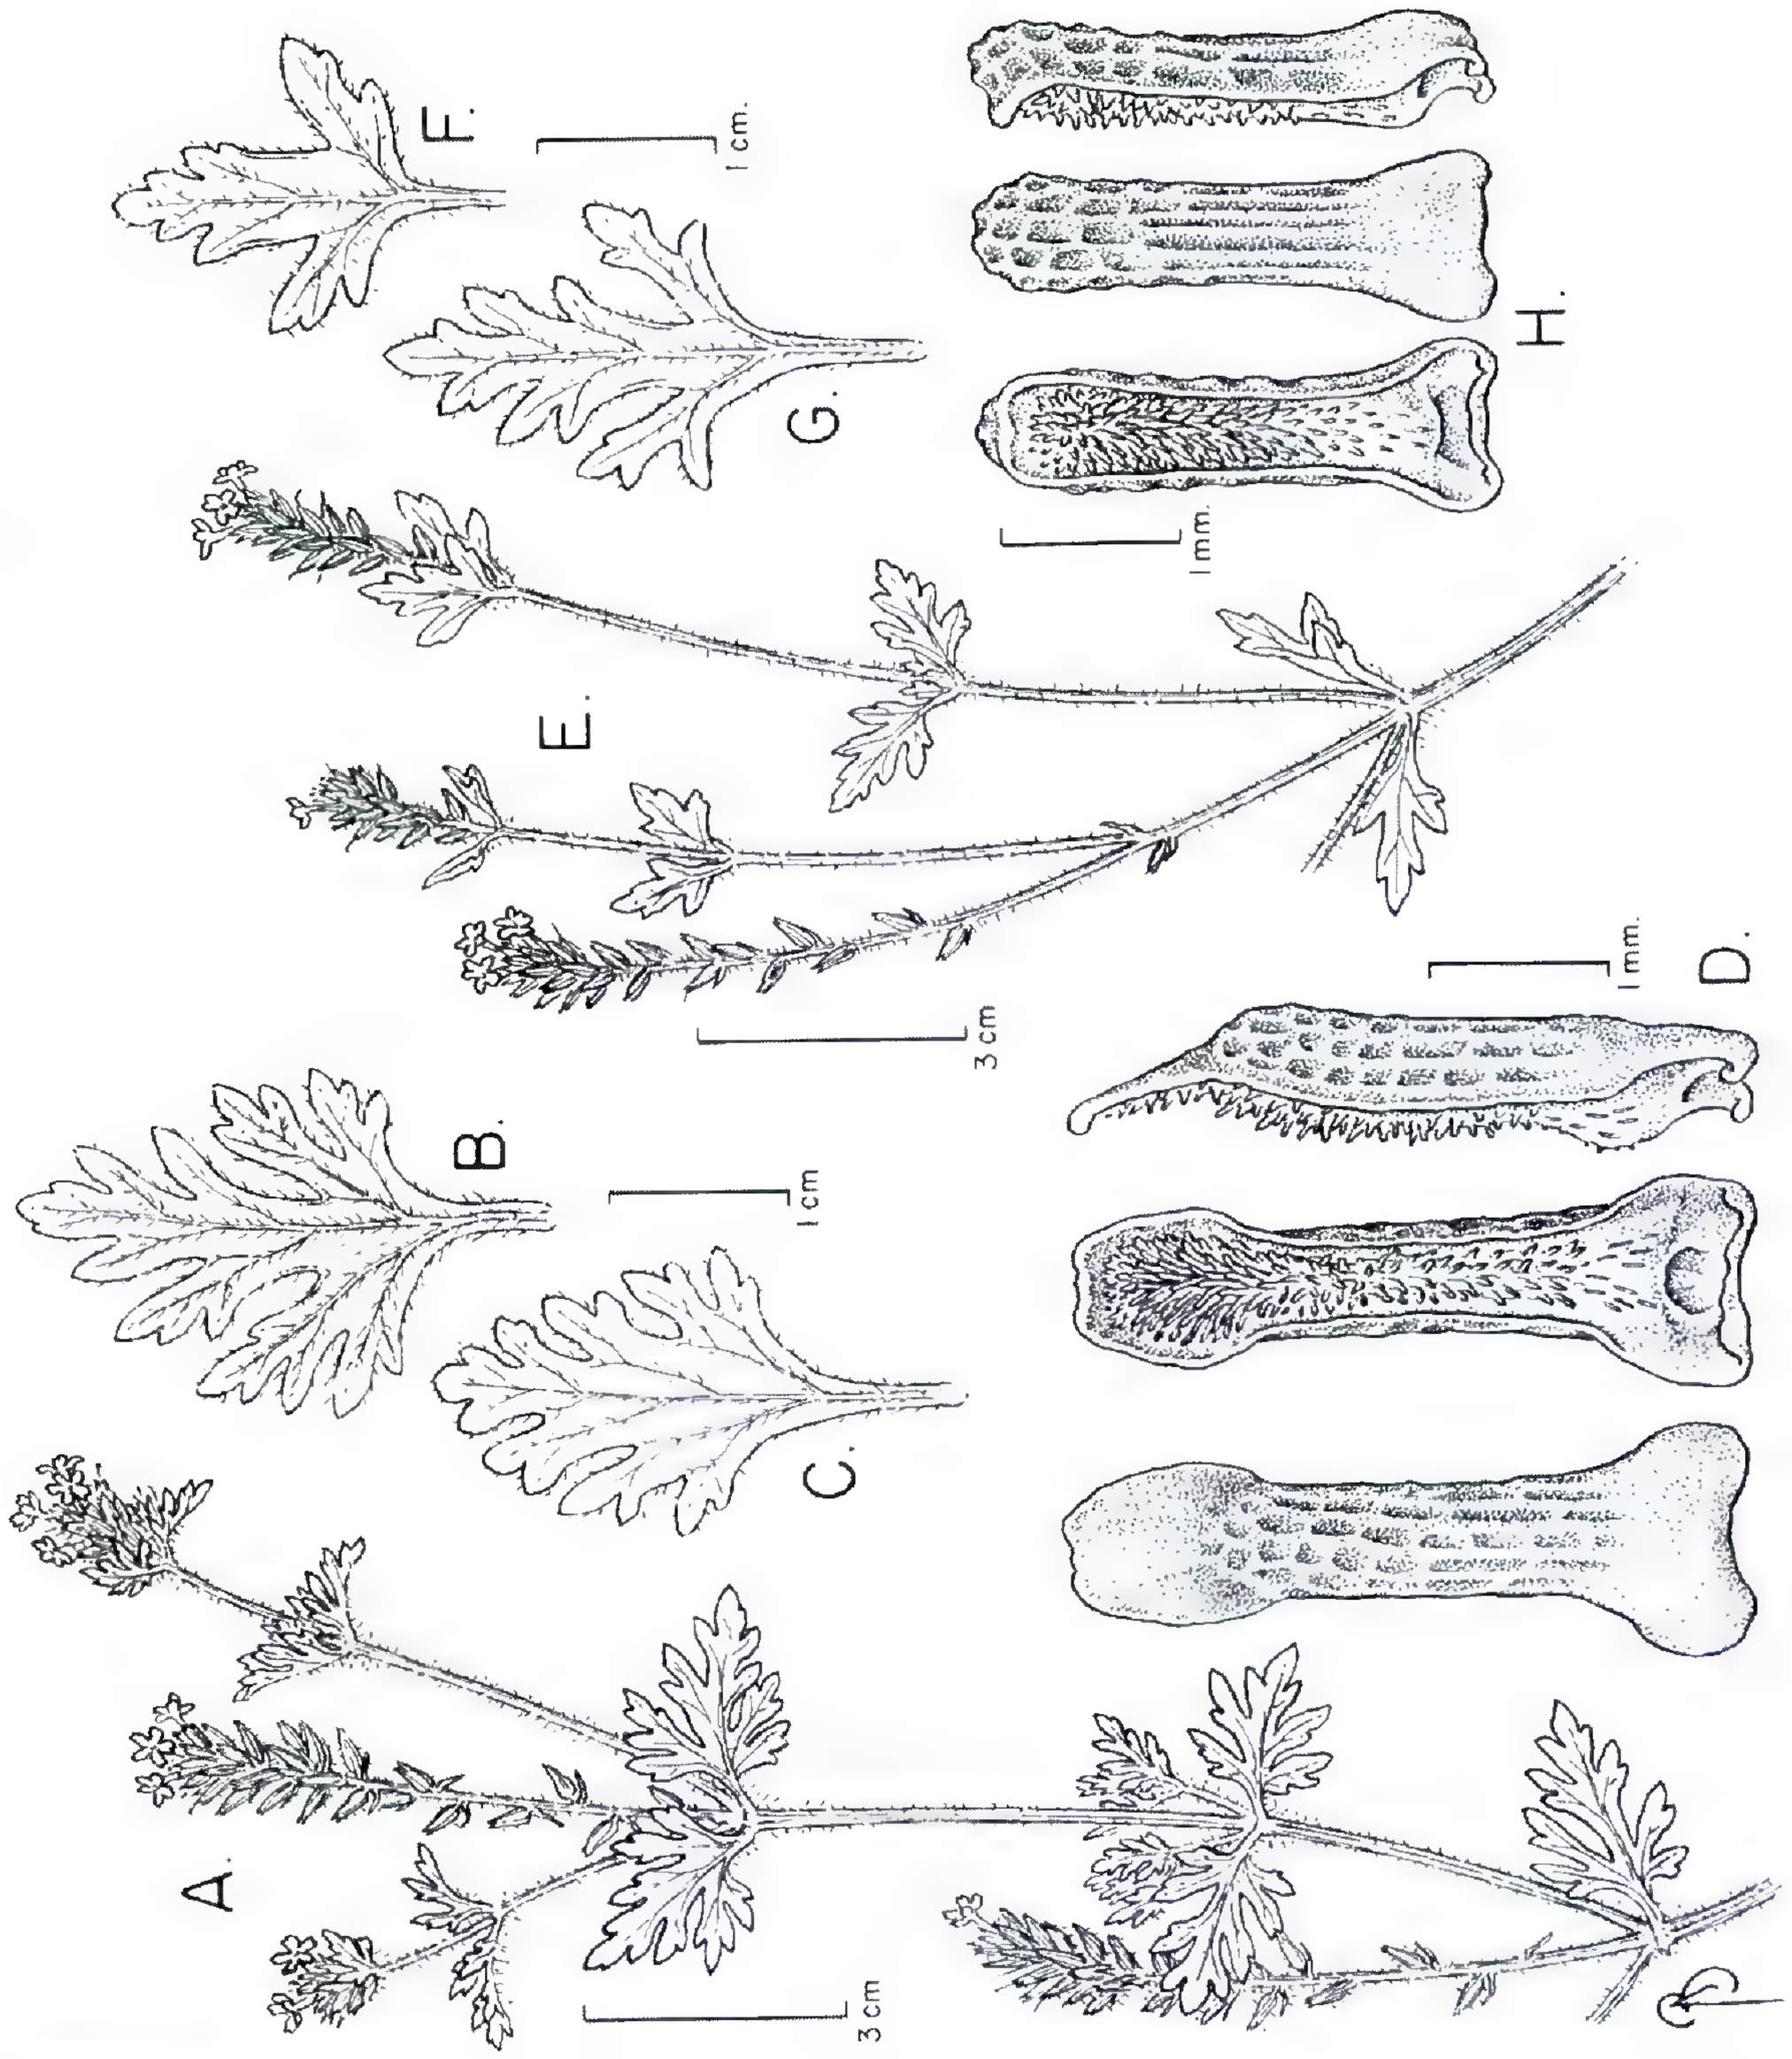

FIG. 1. *Glandularia quadrangulata* and *G. verecunda*. **A–D.** *G. quadrangulata*. **A.** Stem, showing leaves and inflorescences (*Lundell 9790*, LL); **B.** Leaf, adaxial view, (*Lundell 9790*, LL); **C.**–Leaf, adaxial view (*Turner 21-112*, TEX); **D.** Mature nutlets showing the distinctive ovate terminal appendage and broadly flaring basal pericarp as seen in abaxial view (left) showing outer reticulate pattern, (note broad expansion of nutlet base), in adaxial view (central) showing aculeate inner commissural surface nearly as wide as the nutlet, and in lateral view (right) showing adaxial location of the terminal appendage (all *Carr 15923*, TEX). **E–H.** *G. verecunda*. **E.** Stem, showing leaves and inflorescence (*Strohmeyer s.n.* TEX); **F.** Leaf, adaxial view (*Strohmeyer s.n.*, TEX); **G.** Leaf, adaxial view (*Henrickson 22775*, TEX); **H.** Mature nutlets showing lack of terminal appenadage and broad nutlet base in adaxial view (left) with aculeate commissural face nearly as wide as the mid-nutlet and continuing to near the nutlet tip, abaxial view (central) showing abaxial nutlet surface (note: reticulate pattern near the tip that breaks apart below into parallel lines below), and lateral view (right) showing the small beak-like projection at the tip (all *Bruno & Peña 38*, TEX). Magnifications as indicated.

Mexico; most plants show moderate appendages, in some plants they are poorly developed, shorter and more perpendicular to the nutlet axis. Nutlets of both species are illustrated in Burkart and Troncoso (1979).

The nutlets of *Glandularia racemosa*, however, are strongly different and are of a type widely occurring through most North American *Glandularia* (Fig. 2 I). The body of the nutlets are (2.0–)2.2–2.6(–2.8) mm long, slightly broader, the basal pericarps are only slightly expanded and the nutlets are rounded at the tip. Furthermore the whitish aculeate or otherwise marked commissural surfaces are much narrower than the width of the nutlets (often 0.25–0.3(–0.35) mm wide, with the nutlet being (0.55–)0.6–0.77 mm wide), and this whitish commissural surfaces extends to within 0.2–0.4 mm of the dome-like nutlet tips where they are distinctly rounded, not truncated or retuse. The blackened pericarp, however, has a similar raised reticulate pattern in the distal half that disorganizes into a series of vertical striae as in the other two species.

Cytology.—Umber (1977, 1979) presents chromosome counts for the three taxa. Both *Glandularia quadrangulata* and *G. verecunda* are tetraploid with $n = 10$. *Glandularia racemosa* in contrast, is hexaploid with $n = 15$. An older count by Dermen (1936) also shows hexaploidy for *G. racemosa* ($2n = 30$). This would not support submersion of *G. racemosa* into *G. quadrangulata*. Lewis and Oliver (1961) report $n = 10$ (tetraploid) for *G. racemosa* based on a *Lewis & Oliver 5416* collection from Coahuila, Mexico, however, Umber (1977) correctly notes this collection is *G. verecunda*, not *G. racemosa*.

Phytochemistry.—Umber (1977) notes that the west Texas populations of *Glandularia verecunda* and *G. racemosa* are similar in their flavanoids both producing 7-0-gentiobiosides and 7-0-sophorosides of apigenin, luteolin and chrysoeriol, while six south-Texas samples *G. quadrangulata* produced only 7-0-gentiobiosides (but not 7-0-sophorosides) of apigenin (its dominant flavonoid), with only trace amounts of 7-0-gentiobiosides of luteolin and chrysoeriol. The south Texas sample of *G. verecunda*, however, also produced only 7-0-gentiobiosides of apigenin, luteolin and chrysoeriol as in *G. quadrangulata*.

Biogeography.—Each of these three taxa have distinct ranges: *Glandularia quadrangulata* occurs from south-central Texas west to the Pecos River and to the border region of Mexico (Fig. 3). *Glandularia verecunda* occurs in trans-Pecos Texas, scattered in southern Texas, and continues south into Mexico in eastern Chihuahua, eastern Coahuila, south to near Monterrey in Nuevo León. *Glandularia racemosa* is restricted to trans-Pecos Texas (Fig. 3).

Breeding systems.—Flowers in both *Glandularia quadrangulata* and *G. verecunda* are very small having white to lavender corollas with very slender tubes 5.2–6.5 mm in length and limbs 2.5–5.2 mm in diameter. Within the tube, as in all glandularias, the style is initially situated between the two pair of introrse anthers among a series of downward-pointing stiff hairs (see Fig. 2 E–H).

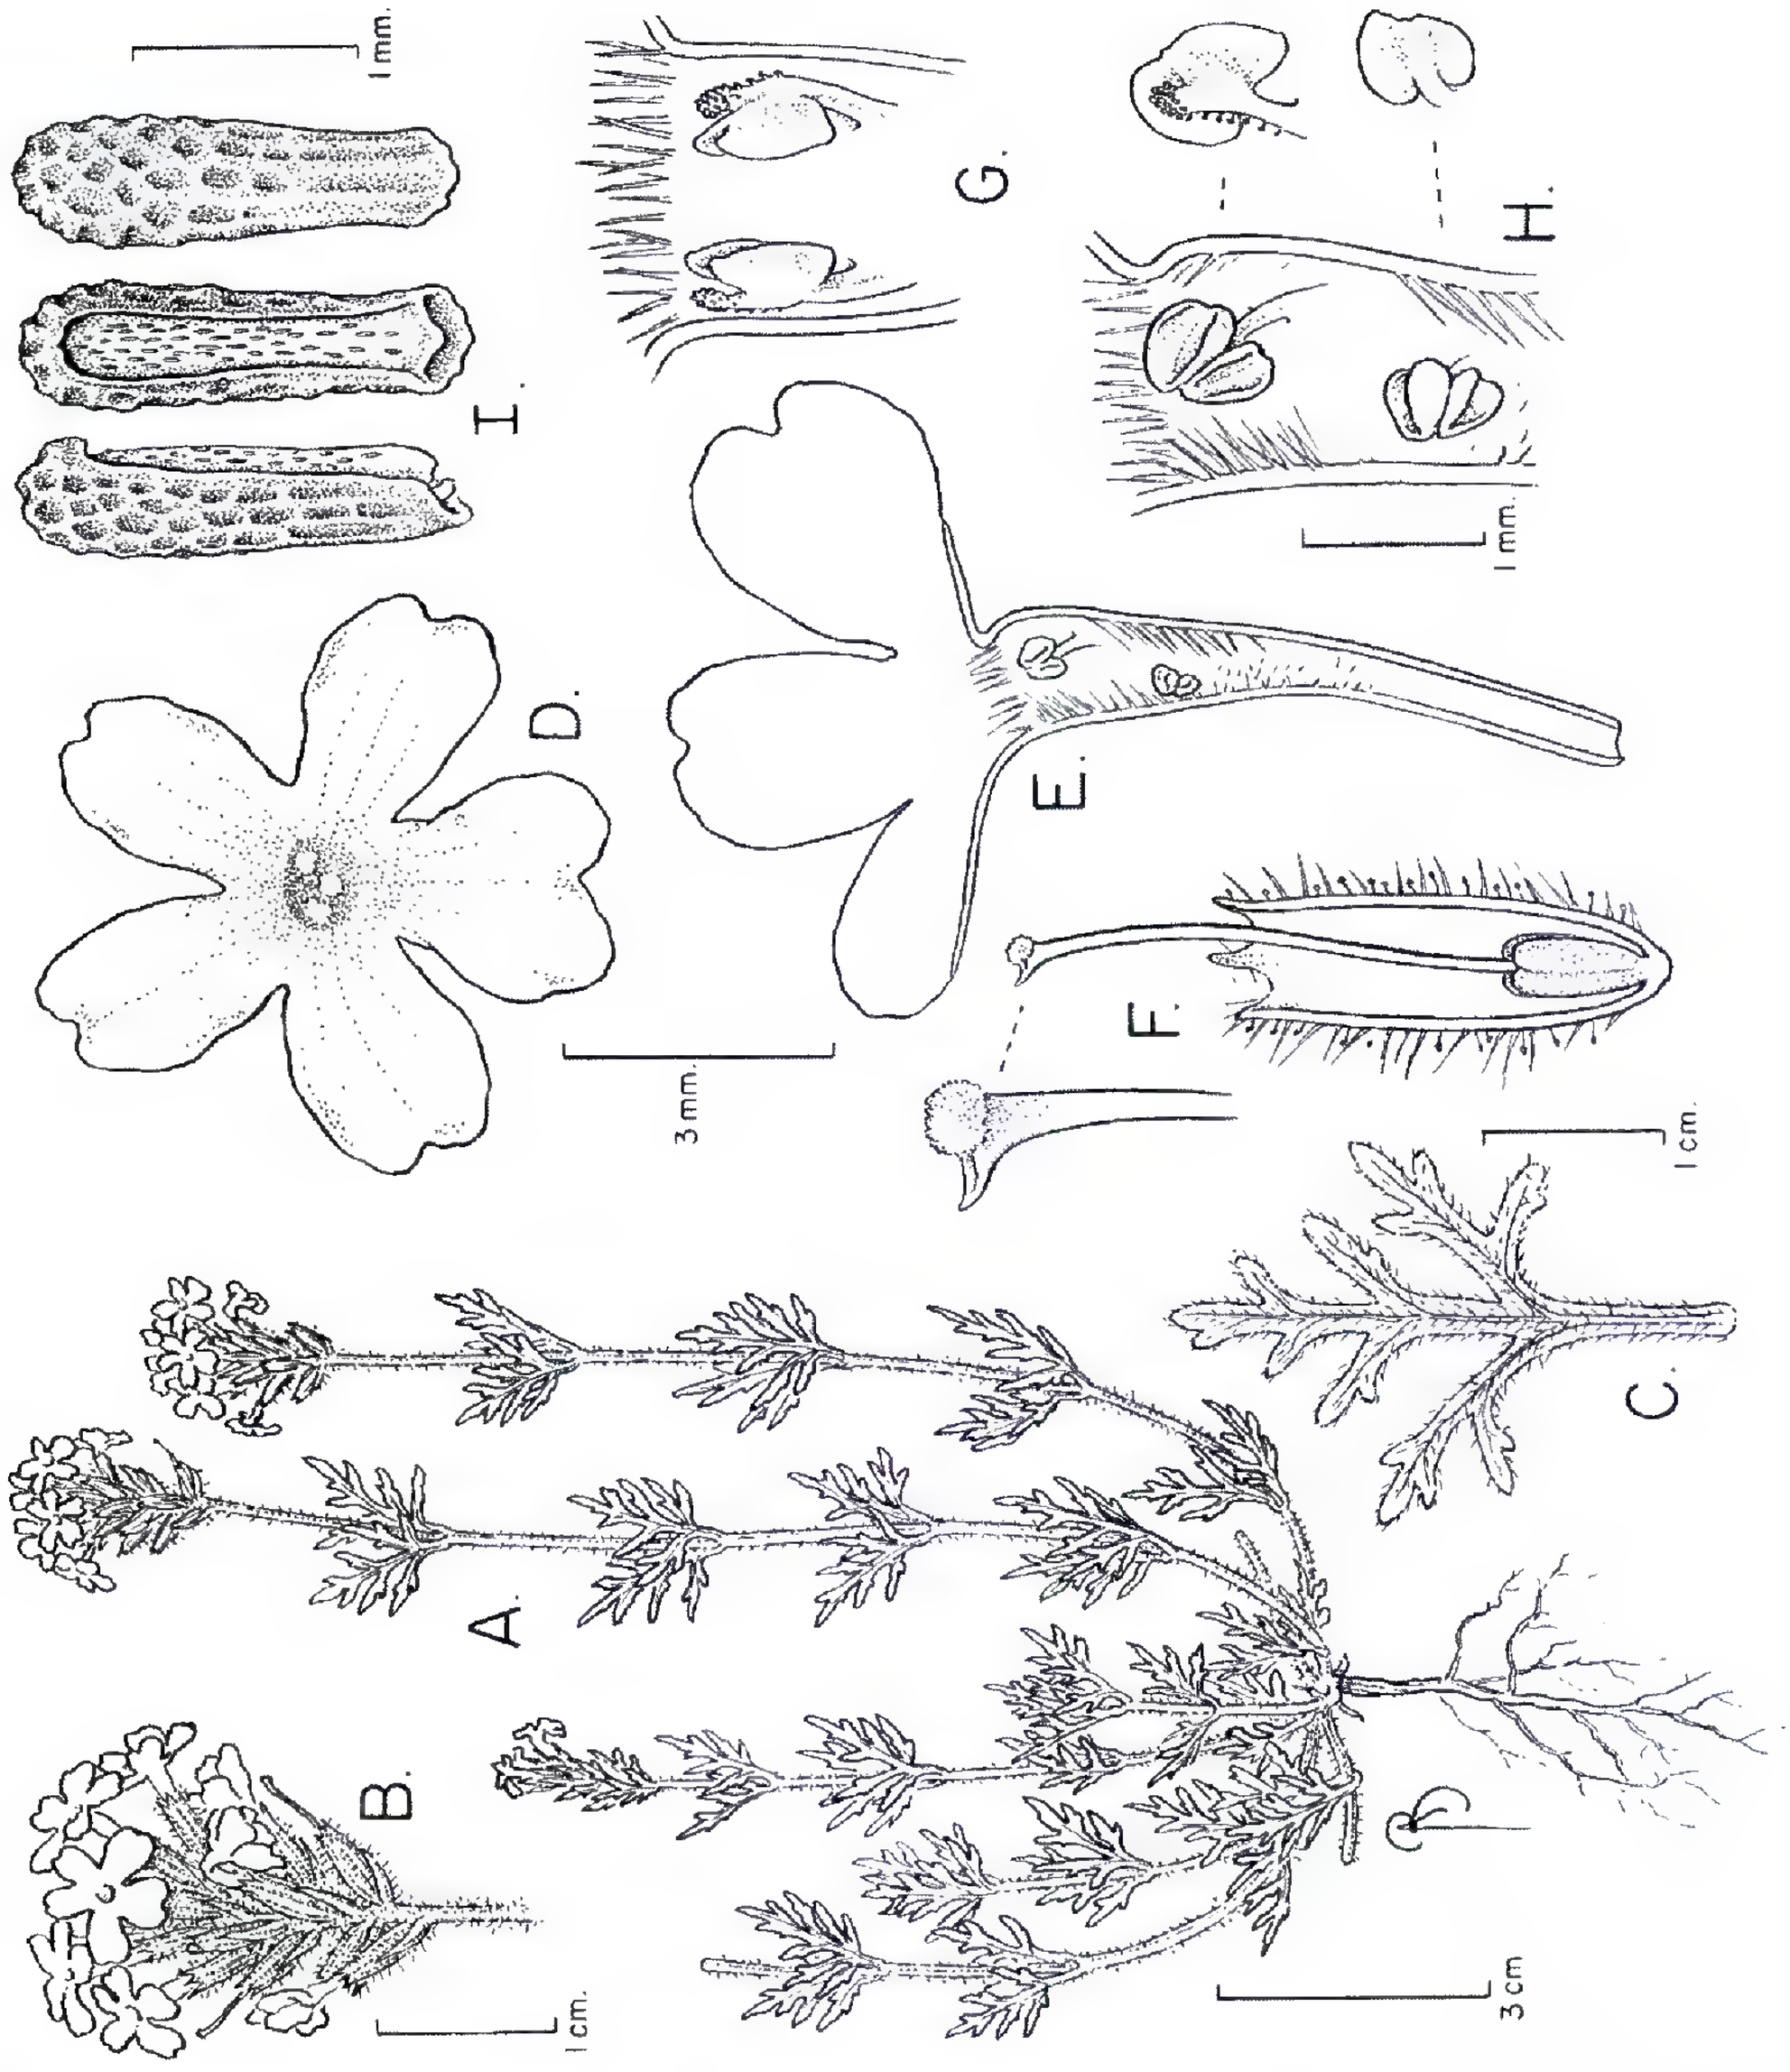

FIG. 2. *Glandularia racemosa*. **A.** Growth habit of young plant showing erect stems and terminal inflorescences (*Turner 21-212*, TEX); **B.** Inflorescence with corollas; (*Turner 21-212*, TEX); **C.** Leaf, adaxial view (*Turner 97-28*, TEX); **D.-H.** Floral structure (from re-expanded flowers of *Turner 21-74* TEX and others) **D.** Corolla, face view, showing larger, more emarginate abaxial corolla limb, and relatively smaller adaxial limbs; **E.** Medial section of corolla, showing separation of distal abaxial and more proximal adaxial stamens, the hairs at the corolla tube throat are moniliform, those of the tube are stiffer, more subulate; **F.** Medial section of calyx, showing ovary, style and stigma (offset). The stigma lies between the two pairs of stamens; **G.** Distal stamens, showing lateral glandular connective appendages; **H.** Distal and proximal stamens and associated hairs (note the connective appendage on the distal stamen–offset); **I.** Mature nutlets showing narrow nutlet base and relatively narrow commissural face, lateral view (left) showing reticulate abaxial surface, adaxial view (central) showing the narrow commissural face, and abaxial view (right) showing the reticulate surface pattern that is less organized below (*Warnock 46135*, TEX). Magnifications as indicated. Scale in D, holds for D, E, and F.

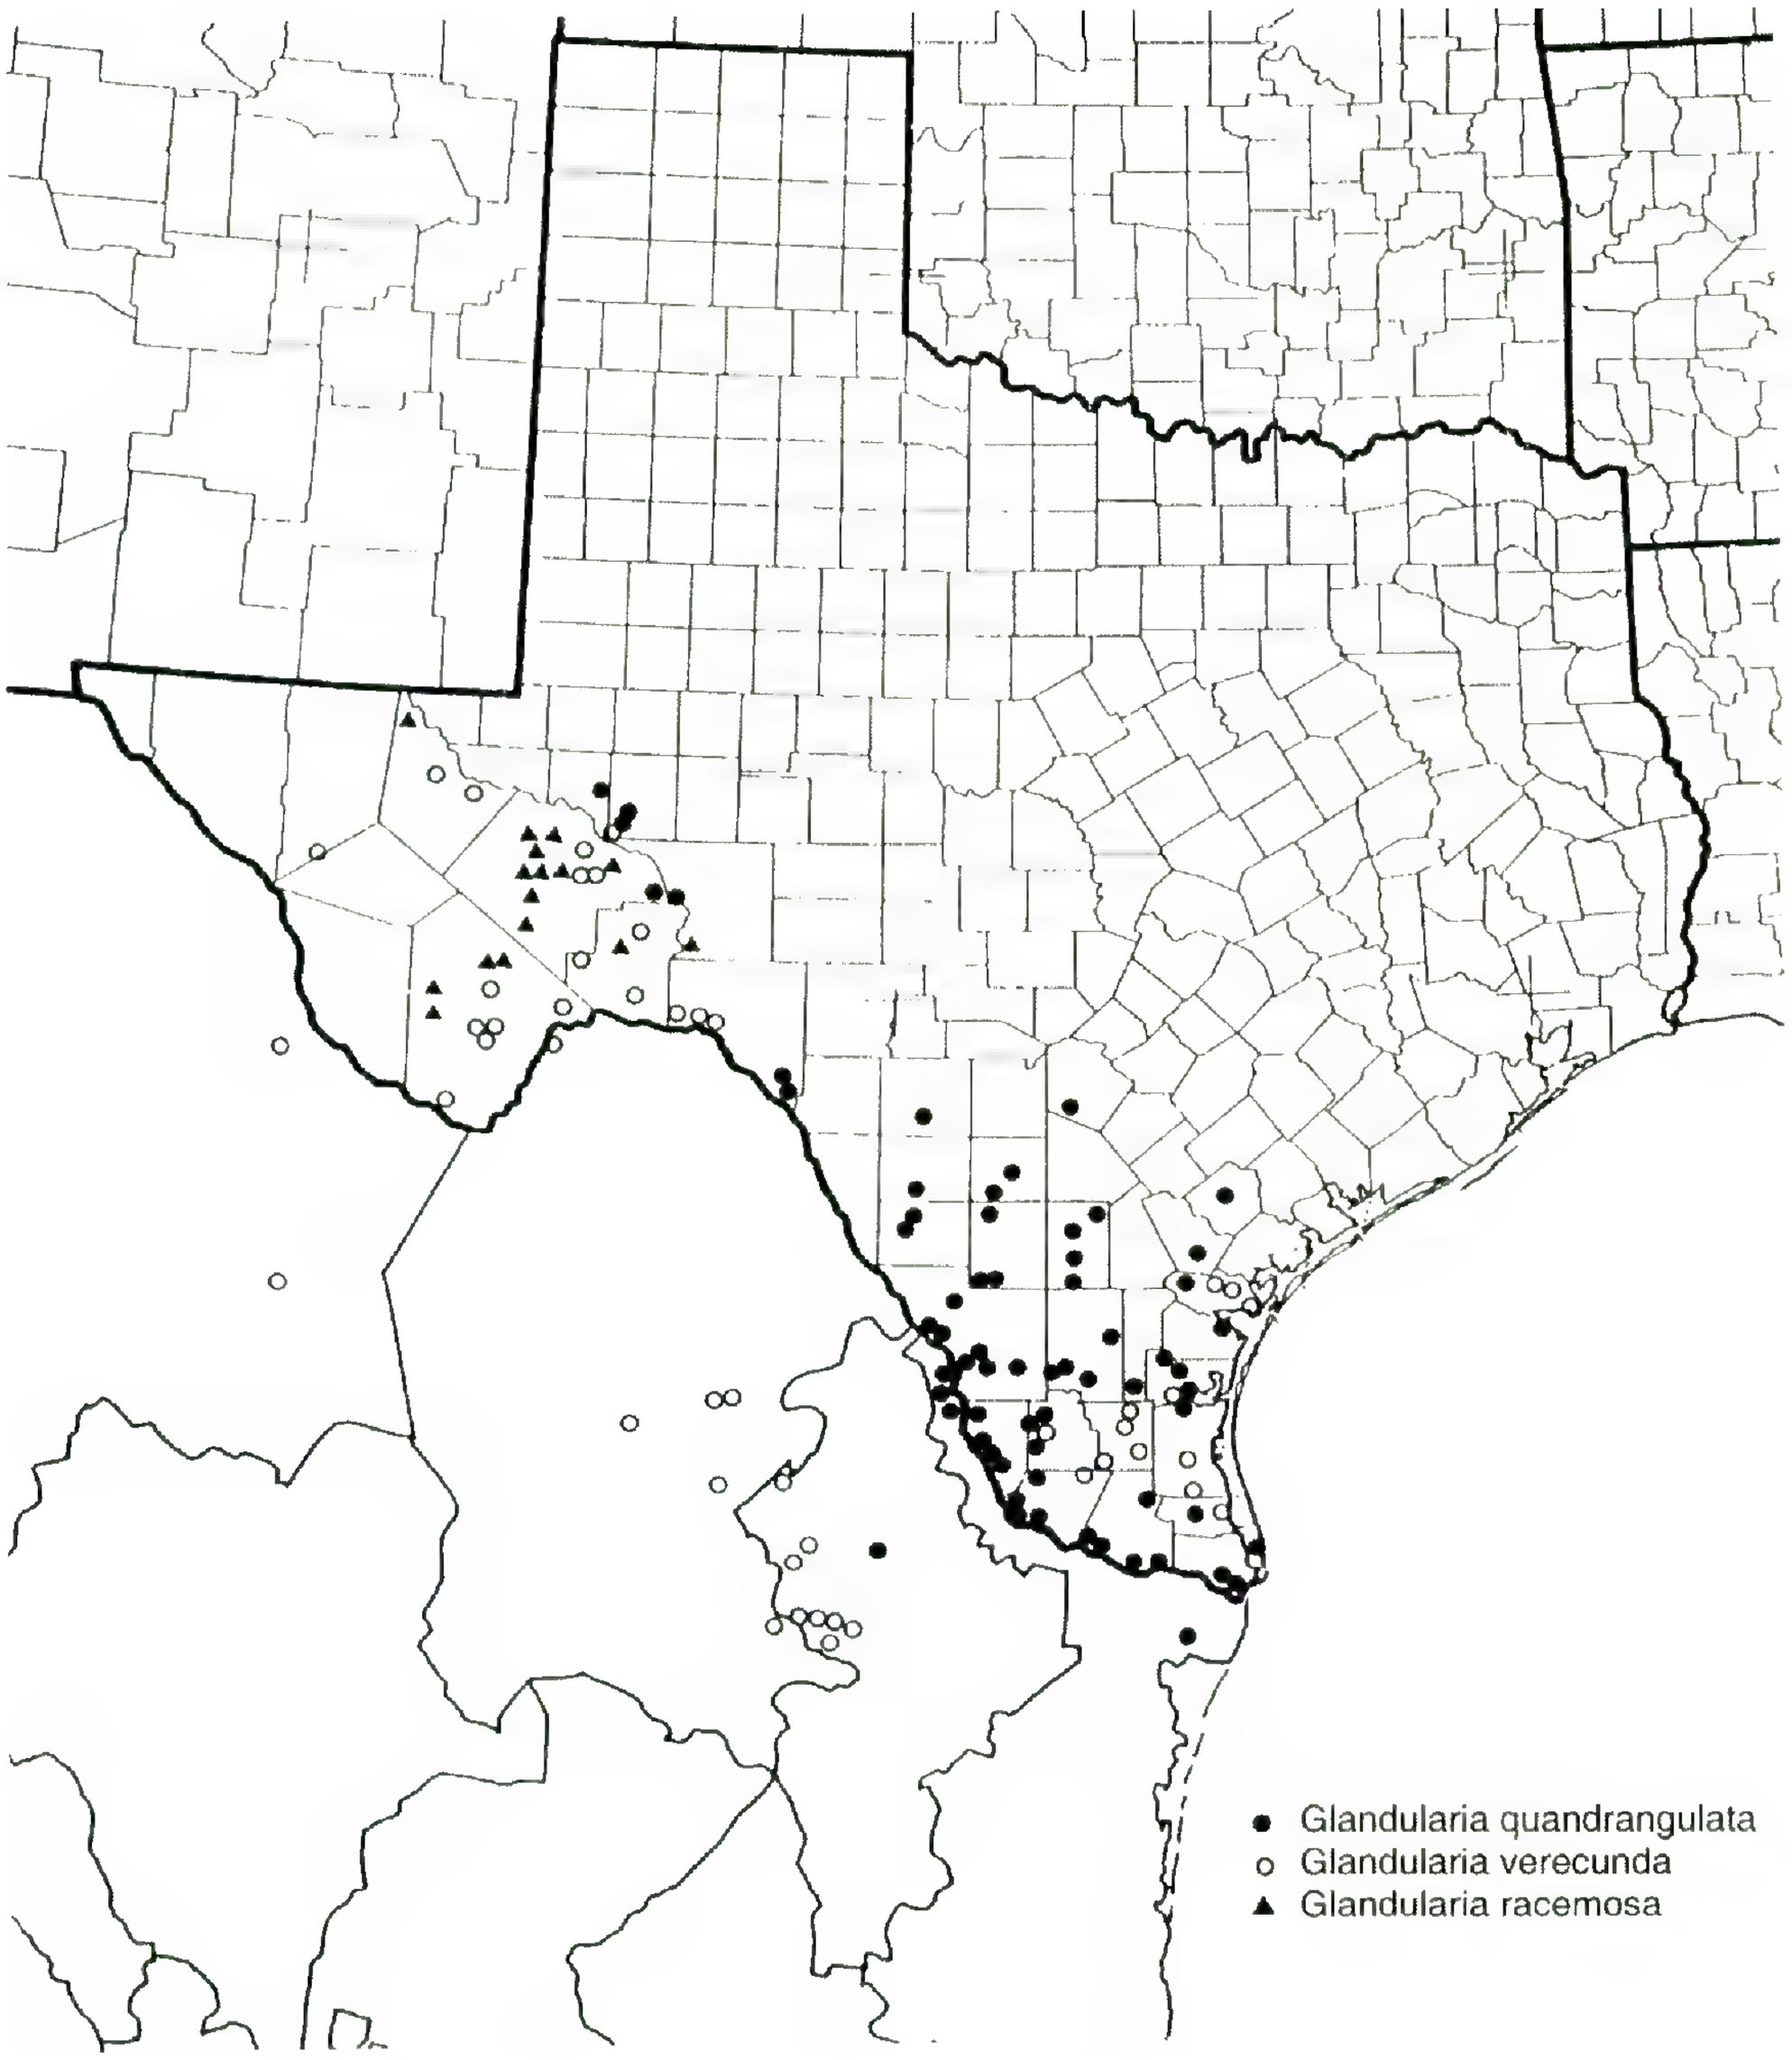

FIG. 3. Distributions of *G. quadrangulata* (solid circles), *G. verecunda* (hollow circles) and *G. racemosa* (solid triangles) in Texas and Mexico, from collections at TEX-LL and SRSC.

The basal two anthers are 0.3–0.6 mm long, with filaments to 0.3 mm long and contain fewer pollen grains than present in the slightly larger distal pair of anthers that are 0.4–0.8 mm long with filaments 0.3 mm long. As the flower matures, the style elongates pushing the stigma across the distal pair of anthers where pollen easily contacts the stigma. Unless some self-incompatability factors are at work, autogamy (inbreeding) is certainly possible. Regarding self incompatibility, I have observed that even isolated plants of *G. quadrangulata* set a full compliment of nutlets, and in most herbarium specimens, the plants have full

fruit set, leading me to believe that there is no self incompatibility involved in the reproduction of the taxon.

Cruden (1977) noted that pollen-ovule ratios can be used as an indicator of the breeding system in flowering plants. In his study, he indicated average pollen/ovule ratios of 4.7 (range 3–7) for cleistogamous taxa; 27.7 (range18–30) for obligate autogamous taxa; 168.5 (range 76–396) for facultative autogamous taxa; 796.6 (range 160–2,558) for facultative xenogamous (outbreeding) taxa; and 5859 (range 1,648–16,807) for obligate xenogamous taxa using his outcrossing index as a relative measure of inbreeding vs. outcrossing.

Glandularia species in North America differ strongly in corolla size, with larger flowers having larger anthers with more pollen. I measured pollen grain numbers per flower and correlated that with overall flower size (using maximum expanded diameter of the corolla limb as a gross measurement of corolla size) in several species of *Glandularia*. I found that plants with corolla limbs 9–13 mm in diameter had 2168–2677 pollen grains (5 counts) (average 2344 per flower, 586 pollen grains per ovule–four ovules per ovary). Flowers with corolla limbs 4–7 mm in diameter had 956–1410 pollen grains per flower (8 counts)(average 1275 per flower, 318 pollens per ovule) and those with corolla limbs 2–4 mm in diameter, had 580–1149 pollen grains (7 counts) (average 748 per flower, 187 pollen grains per ovule) indicating that most *Glandularia* were in the range of facultative autogamous. As noted above, the stigma is also produced in close association with the anthers in the distal corolla tube. For the species here in question, I found in four collections of *G. quadrangulata*, 580, 626, 615, 706 pollen per flower (mean of 157 per ovule-4 ovules per flower), (wetted corolla limb diameters 2.5, 2.5, 2.7, 2.5 mm respectively–see Table 1); for *G. verecunda* 1149, 870, 740, 692, pollen per flowers (mean of 218 per ovule), (corolla limb diameters of 2.5, 3.5, 5.2, 3.5 mm) and *G. racemosa* 2184, 2125, 1728, 1803 per flower (mean of 490 per ovule), (corolla limb diameters of 9.0, 8.5, 8.0, 7.8 mm). This would imply that the taxa, at least for *G. quadrangulata* and *G. verecunda*, are in the range of facultative autogamous taxa and *G. racemosa* is in the facultative xenogamous range.

Also, most plants, even isolated plants, exhibit full or nearly full fruit set. Umber, (pers. comm.) notes that in many *Glandularia* species, greenhouse grown plants produced full fruit set, in some species you had to push the flowering branches back and forth, similar to a wind action, to insure good fruit set. Even the few, widely isolated specimens of *G. quadrangulata* I observed in Kleberg Co., Texas, all had near complete fruit maturation. Though Umber 1977 notes that some populations of his *G. bipinnatifida* have low fruit set, indicating the possibility of local self incompatability. My conclusion is that *G. quandrangulata* and *G. verecunda* are capable of reproducing by autogamy, and that self incompatibility does not restrict fruit set, so that even if they occur in sympatric populations, gene exchange between them may be limited and inci-

TABLE 1. Pollen/ovule ratios of *Glandularia* species.

	Total pollen per fl.	p/o ratio	Corolla diameter
Glandularia quadrangulata			
Turner 97-01 Crockett Co., Tex.	580	145	2.5
W.R. Carr 11723 McMullen Co., Tex.	615	153	2.5
Williges 359 San Patricio Co., Tex.	626	156	2.7
V. Villarreal Kleberg Co., Tex.	706	176	2.5
	Average 157		
Glandularia verecunda			
Correll 20699 Brewster Co., Tex.	1149	287	2.5
Powell, Turner & Sikes Ojinaga, Chih., Mex.	870	217	3.5
Turner 97-86 Terrell Co., Tex.	780	195	5.2
Lundell & Lundell 10071 Brooks Co., Tex.	692	173	3.5
	Average 218		
Glandularia racemosa			
Turner 97-28 Pecos Co., Tex.	2184	546	9.0
Turner 97-212 Culberson Co., Tex.	2125	531	8.5

Tharp& Havard 49359 Pecos Co., Tex.	1803	451	7.8
	Average 490		

dental. Certainly both taxa produce flowers with small corolla tubes that may be attractive to long-tongued flies (J. Neff, pers. comm.) but are certainly capable of self pollination.

Classification.—The relationship of *Glandularia racemosa* to the other two taxa, is very clear. While *G. racemosa* is somewhat vegetatively similar to both *G. quadrangulata* and *G. verecunda*, the leaves of *G. racemosa* are more deeply divided into linear segments (except in some large, perhaps shaded leaves of rapidly-growing specimens), its growth habit is different, initially briefly decumbent at the base with erect-ascending stems, but with age it becomes more spreading. Furthermore the fruits of *G. racemosa* are completely different as

discussed above and are of a type found in most North American *Glandularia*. Also both *G. quadrangulata* and *G. verecunda* are tetraploid ($n = 10$), while *G. racemosa* is hexaploid ($n = 15$). In addition the corollas of *G. racemosa* are larger [(5.5–)6–8(–9.0) mm in limb diameter] than those of *G. quadrangulata* [(2.0–)2.5–3.5(–4.5) mm diameter] and *G. verecunda* [3.2–4.5(–5.5) mm diameter]. Corolla limbs of *G. racemosa* are also usually white in color [rarely tinged with blue—which Umber (1977, 1979) considers indication of introgression with *G. bipinnatifida*], while those of *G. quadrangulata* and *G. verecunda* are more commonly lavender, only occasionally white in color. It is apparent that *G. racemosa* is not a taxonomic synonym of the *G. quadrangulata-verecunda* group and is a distinct, endemic species in trans-Pecos Texas. I find no support for Turner's inclusion of *G. racemosa* into his concept of *G. quadrangulata* other than gross vegetative similarity.

While *Glandularia quadrangulata* and *G. verecunda* have largely allopatric ranges, mixed populations occur near the Pecos River and in southern Texas. In fact there are three herbarium collections at TEX-LL that contain material of both taxa: two from Upton County, Texas, 3.1 miles east of McCamey, 21 Apr 1999, *Turner 99-179* and *99-200* (TEX) and one from southern Texas, Kleberg Co., Texas; Hwy. 77, 2 mi W of Riviera, 15 Mar 1965, *Ramerez & Cardenas 78* (TEX). An additional pair of specimens from SRSC (Brewster Co., Texas, sandy soil along the Rio Grande at Boquillas, 10 May 1933, H.T. Fletcher 1224 (*G. quandrangulata*) 1226 (*G. verecunda*) were apparently collected in the same area. In vestiture, leaf size and shape the two taxa are very similar, if not identical.

The overall similarity and occasional sympatry of *Glandularia quadrangulata* and *G. verecunda* caused Turner (1998) to conclude that *G. verecunda* was only a ex-appendiculate form of *V. quadrangulata* unworthy of formal nomenclatural recognition although he presented no evidence of introgression. But we must ask, what characteristics would be expected in hybrids? Would they have intermediate appendages or no appendage at all and be identical with *G. verecunda*?

No plants have every been discovered in nature with nutlets intermediate in structure between those of *G. quadrangulata* and *G. verecunda*. All plants either have nutlets with or without the distinctive distal appendage. Furthermore, no artificial hybridization has been done to determine the condition that would be expressed in a hybrid. The pattern found with *G. quadrangulata* and *G. verecunda* presents an interesting conundrum. Are the two taxa merely forms of one other, as Turner espouses, separated by only a single character that is either expressed or not, so that hybrids would be identical to one taxon or another? Or are they two separate species that do not or seldom hybridize? Or should they be recognized at least at the infraspecific level?

It remains that the two taxa are nearly identical vegetatively and florally except for the distal nutlet appendage on *G. quadrangulata*. I concede that the

two are most-closely related or sister taxa; to think otherwise would be difficult to defend. But there seems to be a stability in their lineages as indicated by their respective large and mostly independent geographical ranges.

The genetic basis of the nutlet-appendage character is not known. If it is a simple Mendelian trait, it would appear not to have a high mutation rate. If the appendaged nutlet type in *Glandularia quadrangulata* were pleisomorphic and dominant state (i.e., AA, or Aa) and the non-appendaged nutlets represented a loss of this character (i.e., aa), then once a mutation (a) forms, or once hybridization occurs, one would expect the heteozygotic plants to form seeds at a 1:2:1 genotypic ratio (1AA:2Aa:1aa), a phenotypic ratio of 3 appendaged to 1 non-appendaged character state while the homozygous plants would breed true over successive generations. The same pattern would be expected if the appendage were a recessive character state. Whether this is occurring in certain localities is unknown. But it remains that large geographical regions are occupied by plants with either appendaged or non-appendaged nutlets indicating a low rate of mutation or hybridization. If mutation rates were higher, or hybridization more frequent, homozygous recessive traits would be expected throughout the dominant-trait populations.

Turner (1989) has treated the two taxa as unnamed forms, relegating Umber's *G. verecunda* to obscurity. But if the two taxa are facultative autogamous, they could very well become sympatric without mixing and thus behave much like species. Likewise if they are allopatric, and mutation rate is very low, again they would breed true to form and behave as species. To relegate the two taxa to unnamed forma, is not reflective of the conditions observed in nature. In typical formas, the homozygous recessive character states usually occur scattered in some or many populations, their frequency reflecting the frequency of the recessive trait. These two taxa behave more like species. They each have broad geographical ranges. The distinguishing character state is conspicuous. There is a possibility that in some populations, where both taxa are present, they may have introgressed and mixed populations are being produced through recombination. But as there is no intermediate character state, the populations would appear to be consisting of two sympatric separate taxa. If they actually are interbreeding, there would be no way to tell except by growing the nutlets out from these mixed populations to see if they breed true to form. I have visited two populations where the two taxa are sympatric, west of Riviera, in Kleberg Co., Texas and west of McCamby, in Upton Co., Texas in the late spring of 2001. In the former the roadside populations are largely being replaced by Bermuda Grass, but some nutlets were collected from scattered specimens of *G. quadrangulata*. In the Upton County populations, no plants were found presumably due to local rainfall conditions.

Of the three nomenclatural possibilities: (1) being inconsequential forms of each other; (2) being geographical subunits of a species, i.e., subspecies or

varieties of one species; or (3) being separate species that merely co-occur in some areas. I consider that the first choice is least supportable. Mixed populations are few, no plants with intermediate fruit conditions are known to exist, plants with the two fruit types occur in broad, somewhat discrete geographical ranges. This treatment would ignore the pattern of variation as it would not be reflected in the nomenclature. One could argue, just as strongly, that the two taxa are distinct species that are very similar vegetatively that can co-occur without interbreeding as no intermediates have every been found. But the lack of interbreeding may be based in autogamy more than some other type of isolating mechanism.

If there was evidence of interbreeding, they the two taxa could be recognized at the infraspecific level. But this does not exist. Therefore the two taxa will here be recognized as distinct species.

Glandularia quadrangulata (Heller) Umber (**Fig. 1 A–D**). BASIONYM: *Verbena quadrangulata* Heller, Contr. Herb. Franklin Marshall Coll. 1:84. pl. 6. 1895. TYPE: U.S.A. TEXAS. NUECES CO.: Corpus Christi, 5 Mar 1894, *Heller 1388* (HOLOTYPE: (in part) NY; ISOTYPES: GH, MO).

Verbena pumila f. *albiflora* Standl., Field. Mus. Publ. Bot. 4: 256. 1929. TYPE: U.S.A. TEXAS. BEXAR CO.: San Antonio, *L.E. Pagel 2208* (HOLOTYPE: F).

Weak-stemmed annuals 0.5–2 dm tall; stems several from the base, 1–3(–7) dm long, initially briefly decumbent, erect above, with age spreading, decumbent, ascending distally, the internodes (1.2–)2–5(–11) cm long, green to tan, sometimes purple with age, grooved on two sides when young , this obscured when larger, moderately (to strongly below inflorescence) hirtellous to pilose with slender, tapering erect, mostly straight hairs 0.2–1.2(–1.8) mm long, sometimes with stipitate glands to 0.2 mm long. Leaves ovate to ovate-rhombic in outline (12–)15–25(–38) mm long, (8.5–)10–20(–30) mm wide, usually much shorter than the internodes, with petioles 2–11 mm long, the blades 3–5 cleft about half, two-thirds way to the midrib, the clefts entire to few to strongly toothed and lobed, usually moreso on the outer margins, ultimately the leaf with 7–22 oblong to oblong-obovate, obtuse-rounded, sometimes acute lobes 1–2.5(–3.5) mm wide, the blades flat to usually somewhat concave and with impressed primary-secondary veins above, with rather stiff, tapering unicellular hairs 0.3–0.8(–1.1) mm long on both surfaces, these generally dispersed and ascending above, mostly along the yellowish raised veins and the slightly revolute margins (or ± uniformly scattered) beneath, those of the upper surface sometimes pustulate based. Spikes terminal on all branches, initially crowded with a short peduncle, 9–11 mm wide, with age the inflorescence axis elongating below, and the lowermost developing fruit becoming increasingly more remote, until separated by 5–7 mm along the axis, the inflorescences then extending 4–13 cm long with a peduncle to 5 cm long, the spike rachis ± densely pilose with hairs to 1.8 mm long; bracts ascending, linear-lanceolate, 3.2–5.5 mm long, hirsute along margins and

midvein with hairs 0.2–1.6 mm long, 59–79 percent as long as the calyx; calyces initially 5.0–6.5 mm long, membranous between the 5 green veins, hirtellous and hirsute with hairs 0.2–1.2 mm long, without or without stipitate glands, the lobes unequal, 0.4–0.8 mm long, green or purple tipped, in fruit the calyces expanding around the nutlet becoming strongly trunctated and to 2.5 mm broad at the base; corollas slaverform, the slender tubes 5.2–6.6 mm long, 0.4–0.6 mm wide at the throat, the limbs white to lavender, (2.0-)2.5–3.5(-4.5) mm wide, the 5 lobes all retuse, or the upper two lobes not retuse, 1.0–1.2 mm long, 0.5–1.3 mm wide; the tube orifice with gold-white moniliform hairs to 0.5 mm long; distal anthers 0.4–0.5 mm long, the anther gland obscure, with filaments 0.3 mm long, the proximal anthers 0.3 mm long, with filaments 0.2 mm long; style 4–5.2 mm long. Mature fruit (3.3–)3.5–4.2 mm long, the distal, adaxial, obtuse, ovate appendage 1.0–1.4 mm long, 0.8–1.0 mm wide, the central body cylindrical, 0.55–0.65 mm wide, the cream-colored commissural face 0.38–0.55 mm wide, this extending throughout the distal appendage, strongly aculeate with papillae to 0.25 mm long, the basal pericarp expanded, forming a hollow chamber to 1.0–1.6 mm wide, the outer pericarp black, shallowly reticulate in the distal half, the reticulate pattern disorganizing into vertical striae in the lower half, the post-dehiscent receptacle small, not whitish or whitish-cream.

The species is characterized by its moderate to strongly incised leaves that are relatively broad along the midvein (often cleft to only 1/3 to total width), by the small corollas, and by distinctive nutlets that have narrow central bodies, with the pericarp greatly expanding at the base, with a conspicuous, spoon-like appendage nearly 1 mm high at the tip, with the commissural face nearly as wide as the mid nutlet, continuing into the distal appendage. Relationships of the species may also lie with two other species in North america have similar nutlets with broad commissural faces: *Glandularia shrevei* (Moldenke) Umber and possibly *Glandularia bajacalifornica* (Moldenke) Umber (Umber 1979).

Widespread in southern Texas and closely adjacent Mexico also in west Texas near the Pecos River (Fig. 3), in limestone, caliche, gravelly to sandy, clayish soils in coastal prairie, thorn scrub, in cis-Pecos Texas in desertic scrub, often roadsides, open areas, 10 to 1000 m, flowering late February to April.

Glandularia verecunda Umber, Syst. Bot. 4:99. 1979. (**Fig. 1 E–H**). TYPE: U.S.A. TEXAS. REEVES CO.: 2.5 mi E of Toyah, *R. & J. Umber 379* (HOLOTYPE: GH; ISOTYPES: TEX!, NY).

Verbena pumila f. *albida* Moldenke, Phytologia 9:188. 1963. TYPE: U.S.A. TEXAS. KENEDY CO.: at the edge of Kenedy Co., Highway 96 at the Willacy Co. line, 18 Apr 1941, *Runyon 2499* (HOLOTYPE: NY; ISOTYPE: TEX!).

Vegetatively similar to *G. quandrangulata* but the leaves more ovate to obovate in outline (12–)15–25(–42) mm long, (9.5–)10–20(-25) mm wide, with petioles 4–8 mm long, the lateral clefts more often entire or with fewer lateral teeth-lobes, and the hairs more often with pustulate bases. Inflorescence bracts lin-

ear-lanceolate to lanceolate, 3.2–6.5 mm long, 49–87 percent as long as the calyces; calyces 5.5–7.0 mm long, the lobes, 0.4–1.1 mm long, in fruit the calyces to 1.7–2.5 mm broad at the base; corolla tubes 5.5–7.0 mm long, 0.5–0.9 mm wide, the limbs white to lavender, 3.2–4.5(–5.5) mm wide, the 5 lobes all retuse, or the upper two lobes not retuse, 1.4–1.8 mm long, 0.8–2.0 mm wide; the distal anthers 0.6–0.8 mm long, with filaments 0.5–0.7 mm long, the proximal anthers 0.4–0.6 mm long, with filaments 0.2 mm long; styles 5.0–5.2 mm long. Mature nutlets (2.6–)2.8–3.3 mm long, lacking a terminal appendage, the central body 0.5–0.6(–0.65) mm wide, the cream-colored commissural face 0.35–0.5 mm wide, this extending to within 0.05–0.2 of the tip of the fruit, the distal commissural surface truncate or slightly retuse, the inner tip of the fruit with a short inward pointing, tapering, horizontal appendage to 0.2 mm long, the commissural face aculeate with papillae to 0.15 mm long, the basal pericarp expanded, forming a hollow chamber to 1.0–1.3 mm wide, the post-dehiscent receptacle 1.0–1.2 mm wide, whitish-cream in color.

South Texas and trans-Pecos Texas south into eastern Chihuahua, also eastern Coahuila and adjacent Nuevo León (Fig. 3) on calcareous and limestone derived clays, sandy soils, grasslands, thorn scrub, to *Larrea*, *Acacia*, *Hectia* scrub, also disturbed flats, roadsides, milpas; 5-800 m elevation; flowering, March through May, also in Fall with rains.

The taxon is vegetatively similar to that of *G. quadrangulata* has less strong cleft leaves, slightly larger corollas, anthers, and similar nutlets that, however, lack the distinctive distal appendage.

Glandularia racemosa (Eggert) Umber, Syst. Bot. 4:99. 1979. (**Fig. 2**). *Verbena racemosa* Eggert, Torreya 2:123. 1902. TYPE: U.S.A. TEXAS. EL PASO (now Hudspeth) CO.: low sandy valley, Sierra Blanca, 15 May 1901, *H.K.D. Eggert s.n.* (HOLOTYPE: NY; ISOTYPES: GH, MO).

Verbena pulchella Greene, Pittonia 5:136. 1903. TYPE: U.S.A. TEXAS. JEFF DAVIS CO.: Foothills of the Davis Mountains, *Tracy & Earl 106a* (HOLOTYPE: ND-G?; ISOTYPES: NY, GH).

Usually thick-stemmed annuals 0.5–2.5 dm tall; stems initially several from the base, briefly decumbent and erect above, with age more spreading, decumbent, ascending distally, 1–3(–7) dm long, and the plants becoming bushy, the internodes (1.0–)2–4(–6.5) cm long, green, sometimes purple with age, 4-angled, obscurely grooved on two sides when young, moderately to strongly (below inflorescence) hirtellous to pilose with slender, tapering erect, mostly straight hairs 0.2–1.2(–1.4) mm long, sometimes with stipitate glands to 0.2 mm long below the inflorescence. Leaves opposite and in axillary clusters, broadly ovate to ovate-rhombic in outline, 11–25(–45) mm long, (6–)12–22(–26) mm wide, shorter than the internodes, with petioles 2–6 mm long, the blades 2–3 pinnatifid, deeply divided nearly to the midrib, the divisions variously revolute, oblong to lanceolate, 1–7 mm long, 0.8–1.5(–3.5) mm wide, with 7–28 ultimate, acute to obtuse lobes, the blades flat to usually conduplicate with the lobes ascend-

ing, with rather stiff, tapering unicellular hairs 0.2–0.5(–0.8) mm long on both surfaces, these generally dispersed and ascending on both surfaces, the hairs sometimes with pustulate bases, the veins impressed above, broadened beneath, the blades green to grayish due to the vestiture. Spikes terminal on all branches, 10–25(–35) mm long, 11–12 mm wide, densely crowded, the inflorscence axis seldom elongating at the base; peduncles 14–24 mm long, or the spikes closely subtended by leaves, the spike rachis ± pilose with hairs to 1.4 mm long and often with stipitate glands; bracts ascending, linear-lanceolate, 3.3–6.1 mm long, to 0.6–1 mm wide, hirsute along margins and midvein with hairs 0.2–1.1 mm long and with stipitate glands, 51–89 percent as long as the calyx; calyces initially 5–7 mm long, membranous between the 5 green veins, hirtellous and hirsute with hairs 0.2–0.8 mm long, usually with stipitate glands 0.1–0.2 mm long, the lobes unequal, 0.4–1.4 mm long, green or purple tipped, in fruit the calyces becoming trunctated and to 1.5 mm broad at the base; corollas slaverform, the tubes 6–7.5 mm long, expanding to 1.0–1.3 mm wide at the throat, the limbs white or tinged with lavender, (5.5–)6.0–9.0 mm wide, the 5 lobes all retuse, 1.6–3.5 mm long, 1.7–3.8 mm wide; the tube orifice with white or yellow moniliform hairs to 0.7 mm long; distal anterior anthers 0.6–0.8 mm long, the anther gland obscure or extending above the anthers, the filaments 0.5–0.7 mm long, the proximal posterior anthers 0.5–0.6 mm long, the filaments 0.2–0.3 mm long; style 5.5–6.2 mm long. Mature nutlets (2.0–)2.2–2.7 mm long, rounded at the tip, the central body 0.55–0.75 mm wide, the whitish commissural face 0.25–0.3(–0.35) mm wide, this rounded at the tip and extending to within 0.15–0.4 mm of the rounded nutlet tip, weakly aculeate with papillae to 0.1 mm long, the basal pericarp slightly expanded, hollow, 0.6–0.85 mm wide, the outer pericarp black, shallowly reticulate in the distal half, the reticulate pattern disorganizing into vertical striae in the lower half, the post-dehiscent receptacle yellowish, 4-angled, distinct.

Central trans-Pecos Texas (Fig. 3), mostly on limestone derived, calcareous soils, roadsides, mesquite flats, grasslands, with specimens verified from Brewster, Pecos, Hudspeth, Terrell and Reeves counties, Texas, flowering March and April, 2500–4000 ft. elevation. Moldenke 1964b sites additional specimens from Houston, Montgomery, Glasscock, Presidio, ValVerde, LaSalle counties, Texas, as well as San Miguel Co., New Mexico and the Mexican states of Coahuila and Nuevo León. His Montgomery Co., was from Stockton (= Ft. Stockton, Pecos Co., Tex.) His San Miguel Co., New Mexico was from Pecos Valley (= Pecos Co., Tex.) Others were *G. verecunda* or *G. pumila.*

The species has more strongly divided leaf blades, with the blade narrowed to 1/10 of the leaf width at the midvein, and sometimes have a denser vestiture. They have large corollas with tubes 6–7.5 mm long, and limbs 6.2–9.0 mm wide, and nutlets are shorter, rounded at the tip, not strongly expanded at the base, the commissural face is narrower than the nutlet width, and its distal surface is

rounded, not retuse, and the aculeae on the commissural face are reduced to only 0.1 mm in total length.

Glandularia racemosa is easily separated from *G. quadrangulata* and *G. verecunda*, as leaves are more deeply divided, often with a denser vestiture, the corollas limbs are larger, and the nutlets are much shorter, without a broadly outwardly flaring base, the commissural face is notably narrower than the central portion of the nutlet, and the distal portion of the commissural face is rounded, not retuse and occurs 0.15–0.3 below the rounded fruit tip. Umber (1977, 1979) notes relates this species to the *Glandularia bipinnatifida* complex, and reports hybridization between *G. racemosa* and *G. bipinnatifida* documented by mixed flavonoid profiles in the hybrids (Umber 1977).

A separate paper will deal with Turner's (1999) reclassification of the *Glandularia bipinnatifida* complex.

ACKNOWLEDGMENTS

I thank Ray Umber for valuable discussions and a personal loan of a copy of his dissertation, Bobbi Angell for the illustrations, Jack Neff for discussions on potential pollinators, Fernando Chiang for the Spanish abstract translation, SRSC for a loan of specimens, and the University of Texas, Plant Resources Center, for use of facilities.

ABSTRACT

The morphology and anatomy of bracteoles were surveyed in 20 *Amaranthus* taxa in order to determine their taxonomic significance and role. Three types of bracteoles were distinguished: spinose, foliaceous and membranous. The bracteoles retain the C_4 structure of the leaves, but they differ from the latter by the presence of well-developed sclerenchyma and the arch-shaped Kranz bundle-sheath. Protection and photosynthesis are the two functions of bracteoles inferred from their structure. Based on their structure, foliaceous and membranous bracteoles are considered symplesiomorphic, while spinose bracteoles are interpreted as synapomorphic. The spines present at the base of each leaf in *A. spinosus* L. are metamorphosed bracteoles. The shortness of bracteoles in the grain amaranths (*A. caudatus* L., *A. cruentus* L. and *A. hypochondriacus* L.) was found to be a reliable character, which separates them from their wild relatives (*A. hybridus* L. and *A. powellii* S. Watson). The structure of bracteoles may be significant for recognition of taxa in only a few cases: *A. hybridus* L. and *A. powellii* S. Wats.; *A. powellii* subsp. *powellii* and subsp. *bouchonii* (Thell.) Costea & Carretero and *A. blitum* L. agg

RESUMEN

La morfología y anatomía de las bracteolas de 20 taxa de *Amaranthus* fueron examinadas para determinar su significado taxonómico y su función. Se diferenciaron tres tipos de bracteolas, espinosas, foliáceas y membranosas. Las bracteolas retienen la estructura C_4 de las hojas, pero difieren de estas últimas por la presencia de un esclerénquima bien desarrollado y en la forma arqueada de la vaina de los haces de tipo Kranz. Las dos funciones de las bracteolas son la protección y la fotosíntesis según se deduce de su estructura. Basándonos en su estructura, las bracteolas foliáceas y membranosas son consideradas como simplesiomórficas, mientras que las bracteolas espinosas son interpretadas como sinapomórficas. Las espinas presentes en la base de cada hoja de *A. spinosus* L. son bracteolas metamorfoseadas. La cortedad de las bracteolas en los amarantos cultivados como pseudocereales (*A. caudatus* L., *A. cruentus* L. y *A. hypochondriacus* L.) fue encontrada como un carácter que los separa de sus parientes silvestres (*A. hybridus* L. y *A. powellii* S. Watson). La estructura de las bracteolas puede ser significativa para el reconocimiento de taxa sólo en algunos casos: *A. hybridus* L. y *A. powellii* S. Wats.; *A. powellii* subsp. *powellii* y subsp. *bouchonii* (Tell.) Costea & Carretero y *A. blitum* agg.

INTRODUCTION

The genus *Amaranthus* is a group of extremely high economical value. Some species are grown as vegetables and pseudocereals (reviewed by Brenner et al. 2000), while others are among the most important weeds of the world (Holm et

[1]Corresponding author

al. 1997). Additionally, some species are widespread ornamentals and they have a potential as forage crops and as a source of red food colorants (Cai et al. 1988). The taxonomical treatment of some species has proven to be problematic (e.g. Costea et al. 2001; Xu & Sun 2001), and it is proposed that characters of bracteoles may bring forward additional data useful for the classification of the species within this genus. Bracts are modified leaves without an axillary bud, associated with the inflorescence or with individual flowers (McCusker 1999). Bracteoles are secondary bracts borne singly (usually in monocotyledons) or in pairs on the pedicel, the calyx or the perianth of a flower (McCusker 1999). In *Amaranthus*, bracteoles should not be mistaken with the tepals. The later are the units of perianth, which is not differentiated in a calyx and a corolla (McCusker 1999). As Brenan (1961) wrote: "the size and shape of longer bracteoles in the inflorescence, and particularly their length relative to the flowers they subtend, are of great importance in distinguishing several species of the genus *Amaranthus*." In the difficult *A. hybridus* aggregate, the morphology of bracteoles has been used to differentiate grain amaranths (*Amaranthus caudatus*, *A. cruentus* and *A. hypochondriacus*) from their wild relatives (*A. hybridus* subsp. *quitensis*, *A. hybridus* subsp. *hybridus* and *A. powellii* subsp. *powellii*) (reviewed by Costea et al. 2001). The length of bracteoles has also traditionally been used to classify the infraspecific variability of some species such as *A. retroflexus* (e.g., Thellung 1914). We have proposed to reevaluate the bracteoles in *Amaranthus* in order to determine their taxonomic significance.

Amaranthus spp. are C_4 plants and, therefore, exhibit the characteristic Kranz anatomy in the leaves (best described in *A. retroflexus* by Fischer & Evert 1982) and cotyledons (Wang et al. 1993). No anatomical study of bracteoles has been published in *Amaranthus*, and it would be interesting to compare their anatomy with that of the leaves. Furthermore, the structure may indicate their function and could provide new relevant data regarding the evolution of the genus.

Amaranthus spinosus is the only species of the genus that exhibits two spines at the base of each leaf, and Thellung (1914) suggested that the two spines are actually metamorphosed bracteoles. Testing this hypothesis was another objective of this study.

MATERIALS AND METHODS

Morphology of female bracteoles was examined both on herbarium and fresh material. Only the bracteoles subtending the flowers during fructification were taken into consideration. The following herbaria collections were surveyed for the nine qualitative characteristics (see below): BH, BP, BPI, BRIT, CAS, CLA, CM, DAO, DAV, DS, DUKE, FLAS, HAM, I, IBE, ISC, LA, LIL, MICH, MIL, MIN, MO, MSC, MT, NA, OAC, OKL, PRH, QFA, RB, RSA, SMU, SOM, TEX, UCR, UMO, US, UTEP, VAB, VDB, VF and WIS. Additionally, bracteoles were collected from the wild flora (mainly from Romania and Spain) and from cultivated accessions

provided by the USDA and Gatersleben germplasm collections (Table 1). Voucher specimens are preserved in the BUAG herbarium collection, except for the USDA accessions, which are preserved in the US collection. For the anatomical study, twenty bracteoles were collected from each plant, and 15–20 different plants for each species were examined. Bracteoles were fixed in formalin-acetic acid-alcohol (5:5:90) (FAA) and embedded in paraffin. Transverse sections were made at 5–7 mm in thickness and stained with Toluidine Blue. The structure of the bracteoles varies along with their length. The most complete region is usually at the base (0.2–0.4 mm) of bracteoles, and characters refer to this region. Drawings were prepared with a Reichart camera lucida.

List of bracteole characters examined (See the results section for additional explanations.):

a) qualitative characters of bracteoles (Table 2)

1. Bracteole type:
   s, spinose;
   f, foliaceous;
   m, membranous;
2. Branching of mid-vein:
   +, branched;
   -, unbranched;
3. Pattern of mesophyll development along the bracteole's mid-vein:
   +, uniform, mesophyll more or less uniformly distributed along the mid-vein;
   -, not uniform, mesophyll is more developed in certain regions, usually at the middle or above the middle;
4. Color of the mid-vein (examined on dry material):
   g, green (usually dark-green);
   y, yellow to yellowish-brown or reddish;
5. Shape of the median part of bracteoles (vascular tissue + sclerenchyma + mesophyll) as seen in cross-sections (examined only for spinose bracteoles):
   cir, semicircular;
   el, semi-elliptic;
   de, deltoid;
   tri, trilobate;
6. Spatial pattern of Kranz bundle sheath arrangement (only for bracteoles with branched mid-veins):
   sep, Kranz sheath separately surrounds each branch of the mid-vein;
   tog, Kranz sheath encloses all the branches together;
7. Shape of "Kranz cells" as seen in cross-section:
   ro, rounded or square;
   pa, palisade like;
8. Bundle sheath:
   co+, bundle sheath in contact with the lower epidermis at least in some points;
   co-, additional layers of mesophyll are present between the bundle sheath and the lower epidermis;
9. Mesophyll cells (when present):
   pa, palisade-like;
   spo, spongy parenchyma-like;
   tan, tangentially elongated;

10. Sclerenchyma (only for bracteoles with branched mid-veins):
com, compact, enclosing all the vascular tissue;
frag, fragmented, separately accompanying each vein;
11. Base of the wings containing:
m+s, with mesophyll + sclerenchyma;
m, only with mesophyll;
s, only with sclerenchyma;
-, neither mesophyll nor sclerenchyma is present:

b) quantitative characters of bracteoles (Table 3)

1. Length (mm);
2. Maximum width at the base (mm);
3. Length of the spinose apex—only for spinose bracteoles (μm);
4. Angle between wings and the median part;
5. Thickness at the base (measured on cross-sections) (μm);
6. Thickness of the collateral bundle or of the main collateral bundle in the case of branched mid-veins (μm);
7. Thickness of mesophyll (μm);
8. Thickness of bundle sheath cells (μm);
9. Ratio: bracteoles length/ perianth length.

RESULTS

In all the species examined, each flower is subtended by two bracteoles (sometimes only one, or up to four) which are more or less modified compared to the leaves. The bracteoles in *Amaranthus* can be classified as follows:

a) *Spinose bracteoles* (Fig. 1, A–F; Fig. 3A).—Are rigid and have a spiny tip. They have a median part that includes the mid-vein surrounded by sclerenchyma and mesophyll, and two membranous lateral parts that we shall name "wings," due to of their membranous appearance. The sclerenchyma is more developed than the mesophyll, conferring the hard and rigid appearance of bracteoles. As seen in cross-sections, the median part can be semicircular (Fig. 1C, E) semi-elliptic (Fig. 1D), deltoid (Fig. 1B, F) or even trilobed (Fig. 2A) (Table 2). The wings are not arranged in the same plane with the median part. They form a characteristic angle with the median part, which is maintained even in cross-sections (Table 3). Representative species: *Amaranthus powellii* (Fig. 1E).

TABLE 2. Data matrix for qualitative characters in some species of the genus *Amaranthus* (Amaranthaceae). See "material and methods" for the numbered characters; na = not aplicable.

A. crispus	m		-	g	na	na	ro	co+	na-spo	na	na
A. deflexus	m	-	-	g	na	na	ro	co+	na-spo	na	na

b) *Foliaceous bracteoles* (Fig. 2C–F).—Resemble more a small leaf, and they do not exhibit an obvious differentiation between the median and lateral parts. The mesophyll is more developed than the sclerenchyma, and as a result, the bracteoles are mostly green. The wings are narrow. Representative species: *A. blitoides* (Fig. 2E–F).

c) *Membranous bracteoles* (Fig. 2B).—Resemble the foliaceous bracteoles, but the mesophyll is poorly developed, restricted along the mid-veins, and is often reduced to the one-layered bundle-sheath. Sclerenchyma is also scarcely developed. The rest of the bracteole is thin, and membranous (as in the wings of the spinose bracteoles). Representative species: *A. crispus*. Transitional forms between the foliaceous and the membranous types occur in several species (*A. blitum* subsp. *blitum* and *A. viridis*).

The structure of bracteoles is simple: they have a dorsiventral structure, and they are composed of epidermis, mesophyll, vascular tissue and sclerenchyma. The marginal-meristem activity is intense; its cells proliferate as monolayers

and give rise to the wings. Venation is poor, but the vascular tissue is accompanied by well-developed sclerenchyma. Particularly the lower epidermis may have anomocytic stomata, with three to six neighboring cells surrounding the guard cells. Sparse, multicellular, uniseriate trichomes may occur in all species, especially toward the base of the bracteoles. The vascular tissue consists of a single colateral bundle surrounded by sclerenchyma and a bundle sheath. In some of the species examined—*A. spinosus*, *A. palmeri*, *A. blitoides* and *A. blitum* subsp. *oleraceus*—the mid-vein branches (Fig. 2D–F; Table 2). In all species, the bundle sheath exhibits the "Kranz syndrome" characteristic of the leaves. The fundamental difference is that the bundle-sheath is incomplete, with the cells arranged in an arc around the sclerenchyma. The bundle sheath cells are tightly packed together, they have thicker walls, and their chloroplasts are larger than those of the mesophyll cells. In the species with bracteoles possessing a branched mid-vein, the "Kranz" bundle sheath can separately follow each branch (*A. blitum* subsp. *oleraceus*, Fig. 2D), or it can enclose all the branches together (*A. palmeri* and *A. spinosus*, Fig. 3A). In *A. blitoides* both situations may be encountered in the same bracteole: the Kranz bundle-sheath may be continuous at the base of the bracteoles (Fig. 2E) and fragmented above their middle (Fig. 2F). The mesophyll is homogenous and distributed only along the abaxial face. Its cells, arranged in up to four layers, can be palisade-like (Fig. 1C, E; Fig. 2A), spongy parenchyma-like (e.g. Fig. 1D) or, tangentially elongated (e.g. Fig. 1B) (Table 2). The mesophyll can be uniformly distributed along the mid-vein, or the mesophyll may develop preponderantly along certain regions of the bracteoles (usually in the middle and above). In the first case, the mid-vein morphologically appears "constant," gradually decreasing along its course towards the apex. In the second case, the mid-vein appears enlarged above the middle of the bracteoles. The sclerenchyma in spinose bracts is strongly developed, compact, engulfing the mid-vein and, when present, its secondary branches (e.g. in *A. spinosus* and *A. palmeri*). In foliaceous and membranous bracts with branched veins, sclerenchyma can be compact or fragmented, separately accompanying each branch (Fig. 2D) (Table 2). The wings have several layers of cells at their base and they are one-layered in the rest. The base of the wings may exhibit only mesophyll cells, only sclerenchyma, mesophyll and sclerenchyma cells or none one of these (Fig.1; Table 2). The monolayer of wings has thickened cell walls and may contain calcium oxalate crystals.

Origin of spines in Amaranthus spinosus.—This study supports Thellung's (1914) hypothesis. The two spines present at the base of each leaf are the metamorphosed bracteoles of the first flower within the first dichazial cyme, whose development is suppressed. No floral rudiments were observed in the vicinity of the developing spines which indicates that the suppression is achieved very early in the ontogeny. In an incipient stage of development, spines are similar to bracteoles (Fig. 1A). However, in bracteoles, the development of sclerenchyma

is rapidly completed. The growth of spines involves primarily cell expansion. Sclerosis is delayed until the parenchyma cells enlarge up to five times compared to the parenchyma cells of the bracteoles. Only then is the development of sclerenchyma completed (Fig. 3B). The marginal meristems make at most a limited contribution to the development of the spines, and consequently the wings are reduced or entirely absent (Fig. 3A, B). Mesophyll is present at least towards the base of spines and the vascular supply is similar to that of the bracteoles (Fig. 3B). *Amaranthus spinosus* has a form—f. *inermis* Lautersbach and Schumann—that has no spines, or with spines that are bracteole-like, subtending the first dichazial cyme of each leaf. We believe this form can be regarded as the ancestral type, from which the spiny plants derived. We observed a similar tendency of bracteoles' transformation in some individuals of *A. powellii*. However, the degree of sclerenchyma development never attains the levels observed in *A. spinosus*, and the process is not accompanied by the developmental suppression of the first cyme.

DISCUSSION

Taxonomic significance of bracteoles.—Taking into account the foliar origin of bracteoles, their phylogeny can be speculated upon. The primitive condition in *Amaranthus* is represented by the foliaceous and membranous bracteoles, while the spinose bracteoles can be considered a synapomorphy. Consequently, the most primitive *Amaranthus* species are those classified in the subgenus *Albersia*, while those from the subgenus *Amaranthus* are more evolved. This hypothesis is also supported by the evolution of other characteristics such as the dehiscence-indehiscence of fruits (Costea et al. in press) and the vascular system (Costea & DeMason 2001).

Based on the populations and accessions used, only a few of the taxonomically difficult species with spinose and foliaceous bracteoles could be separated using anatomical characteristics. Furthermore, such characteristics are even less significant in the species with membranous bracteoles, due to their extreme reduction. The anatomic differences between grain amaranths and their wild relatives are minute (Table 2, 3; Fig. 1), and it is possible that these differences will be found to be even less significant when more accessions are examined. There are no differences between *A. hybridus* subsp *hybridus* and *A. hybridus* subsp. *quitensis* which are considered different species by some authors (e.g. Xu & Sun 2001). In the *A. hybridus* agg., Townsend (1988) and Stace (1997) consider the names *A. powellii* and *A. hybridus* as taxonomic synonyms. Even if other morphological characters can easily differentiate these taxa, the distinctiveness of their bracteole anatomy supports their separate recognition (Fig.1 D-E; Table 2, 3). Another taxonomic controversy exists between *A. powellii* and *A. bouchonii* (reviewed by Costea et al. 2001). The morphologic and anatomic differences between their bracteoles support the recognition of *A. bouchonii* as

an infraspecific taxon of *A. powellii* (Costea et al. 2001) (Fig. 1 E–F; Table 2, 3). In *Amaranthus blitum* agg., the three subspecies—subsp. *blitum*, subsp. *oleraceus* and subsp. *emarginatus* are dissimilar with respect to anatomy of the bracteoles:

1. Mid-vein of (foliaceous) bracteoles branched _____ **A. blitum** subsp. **oleraceus** (Fig. 2D)
1. Mid-vein of bracteoles unbranched.
   2. Bracteoles foliaceous (rarely membranous). Cells of the Kranz bundle sheath are separated by the cells of the lower epidermis by a 1–2 layered mesophyll _____ **A. blitum** subsp. **blitum** (Fig. 2C)
   2. Bracteoles membranous. Cells of the Kranz bundle sheath are in contact with the cells of the lower epidermis (mesophyll is absent) _____ **A. blitum** subsp. **emarginatus** (Fig. 2B)

The length of bracteoles and the ratio between bracteole and tepal lengths have been used in the past to classify the infraspecific variability of some *Amaranthus* species (e.g. Thellung 1914; Brenan 1961). For example, the individuals with short bracteoles (equaling the flower perianth) were designated as var. *delilei* (Rich. & Lor.) Thell. in *A. retroflexus*. Such forms are not encountered at the population level, presumably because the short bracteole type is selected against. Based on our current knowledge, such plants cannot even be considered ecophenes, because the shortness of bracteoles can hardly be associated with any ecological advantage. In contrast, the morphology of the bracteoles is one of the few characters that differentiate the grain amaranths (especially *Amaranthus caudatus* and *A. cruentus*) from their wild relatives *A. hybridus* (incl. *A. quitensis*) and *A. powellii*. Thus, the spinose bracteoles of grain amaranths are shorter and thinner compared to those in their wild relatives. This may seem a contradiction with the previous conclusion, but in this particular case the morphology of the bracteoles is important. Domestication of grain amaranths goes back in time more than 7000 years (Sauer 1993), and this character—even if quantitative—is probably genetically fixed. The shorter and softer-spined bracteoles were selected for under domestication because they facilitate harvesting. The survey of many herbarium specimens revealed that cultivated grain amaranths consistently have short bracteoles. Only some specimens of *A. hypochondriacus* may exhibit long bracteoles (comparable with those of *A. powellii*), similarly as in *A. retroflexus* some individuals may have short bracteoles. The distinctiveness of grain amaranths is also supported by morphological (Costea et al. 2001), anatomical (Costea & DeMason 2001), cytological (reviewed by Greizerstein et al. 1997) and molecular data (Xu & Sun 2001).

Bracteoles versus foliage leaves in Amaranthus.—In many plants (e.g., *Chrysosplenium* spp., *Euphorbia* spp., *Melampyrum* spp., Costea unpublished) a continuous morphological and structural transition occurs between foliage leaves and bracts on the same plant. In amaranths, such a transition does not exist. Bracteoles in amaranths are sharply differentiated from the leaves. Several tissues of bracteoles show a reductive tendency. Bracteoles have fewer stomata,

their mesophyll and vascular tissue are less developed, and the Kranz bundle sheath is incomplete. In addition to this developmental abbreviation, formation of new structures without a counterpart in leaves occurs. An example is the sclerenchyma that is absent in *Amaranthus* leaves (e.g. Fisher & Evert 1982; Viana 1993; Esparza-Sandoval et al. 1996), but is an important tissue in the bracteoles. Marginal-meristem activity is intense, giving rise to the one-layered membranous wings, which are also absent from the leaves.

Based on their structure, *Amaranthus* spp. leaves belong to a variant of the Atriplicoid type, having a continuous Kranz sheath around the bundles (reviewed by Dengler & Nelson 1999). However, in the bracteoles, the organization of the Kranz cells in arcs is entirely different from this type, and it calls to mind other C_4 leaf structures described in *Chenopodiaceae* such as the kochioid and solsoid types (reviewed by Dengler & Nelson 1999; Jacobs et al. 2001). Since bracteoles are ontogenetically abbreviated leaves, one cannot refrain from speculating on the old idea that "ontogeny recapitulates phylogeny" (See Gould 1977). It is a fact that *Amaranthus* shares close morphological, structural (Costea & DeMason 2001) and molecular affinities with Chenopodiaceae (reviewed by Cuénoud et al. 2002) and these new data provide additional evidence in this respect.

Functions of bracteoles in amaranths.—Two functions can be inferred from the structure of bracteoles in *Amaranthus*: photosynthesis and protection. Bracts (in general) are metamorphosed leaves. Although the degree of modification varies in different genera and families, the other functions of the bracts are subsequently added to the primordial role of photosynthesis. When present, bracts may participate in the development of flowers, fruits and seeds. For example, the contribution of bracts to the achene maturation in *Carpinus* spp. (Hori & Tsuge 1993) or to the development of buds in *Gossypium* spp. (Zhao & Oosterhuis 1999) was found to be significant. Studies made on *Gossypium* spp. showed that the removal of bracts reduced the cotton-boll size and the number of seeds per boll (e.g. Bangal et al. 1985; Ahmed 1994). Similar results—a lower seed yield—were reported after removing the phyllaries from the antodia of *Carthamnus tinctorius* and *Helianthus annuus* (e.g. Dhopte & Lall 1981; Hayashi & Hanada 1986). In *Amaranthus*, due to the huge number of flowers that develop in the inflorescences, the photosynthetic role of bracteoles should not be underestimated. A single plant of *Amaranthus retroflexus* can produce approximately 1 000 000 seeds (Hanf 1983). Assuming that the number of female flowers in the inflorescence is at least equal to the number of produced seeds, this would mean there are at least 2 million bracteoles in one inflorescence. Therefore, photosynthesis in bracteoles may significantly contribute to the development of the enormous number of small seeds and consequently to the ecological success of amaranths, especially as weeds. However, this hypothesis needs to be verified and the contribution of bracteoles to total photosynthesis to be established.

In many plants, protection is the most common function acquired by bracts,

which is performed in a multitude of ways, against a multitude of factors. Protection can be limited to the inflorescence and flowers, or it can also be extended to the developing fruits as well. In *Heliconia* the liquid produced in the bracts contributes to the protection against herbivores (Wooton & Sun 1990). Association with ants as a result of extrafloral nectaries developed on bracts provides a defense mechanism against a wide variety of predators (e.g. Scott 1981; McLain 1983). In *Rheum nobile*, an alpine plant, bracts absorb UV radiation and keep the reproductive organs warm (Omori et al. 2000). Mechanical protection of both flowers and fruits against herbivores is obvious for the spinose bracteoles in *Amaranthus*. There seems to be a correlation between the presence of spinose bracteoles and the dehiscence of fruits: species with dehiscent fruits have spinose bracteoles, while species with indehiscent fruits have membranous or foliaceous bracteoles (although a few exceptions exist). One of these exceptions is *A. powellii* subsp. *bouchonii* that has indehiscent fruits and spinose bracteoles. Yet, this taxon has shorter and thinner bracts compared to *A. powellii* subsp. *powellii*, its closest relative with circumscissile fruits (Costea et al. 2001). Furthermore, in monoecious and some dioecious species (e.g. *A. palmeri*) the bracteoles of the female flowers are more developed than the bracteoles of the male flowers. The abortive female flowers of hybrids are subtended by longer (than normally) bracteoles (Brenner, unpublished).

In conclusion, based on the populations and accessions examined, bracteoles are important for the species delimitation in *A. hybridus* agg. and for the separation of subspecies in *A. blitum*. The anatomical study of bracteoles, along with other characters (the vascular system and the structure of fruits) indicates that subgenus *Albersia* has a basal phylogeny within *Amaranthus*, while the species of the subgenus *Amaranthus* are derived. Protection and photosynthesis are the main functions deduced from the structure of the bracteoles.

BOOKS FROM TIMBER PRESS

DAVID V. ALFORD. 2003. **A Color Atlas of Pests of Ornamental Trees, Shrubs and Flowers**. (ISBN 0-88192-561-6). Timber Press, Inc., 133 S.W. Second Avenue, Suite 450, Portland, OR 97204-3527, U.S.A. (Orders: www.timberpress.com, 800-327-5680, 503-227-2878, 503-227-3070 fax). (Note: Timber Press holds North American rights only; Manson Publishing in England is the originating publisher). $59.95, 448 pp., 1069 color photos, 7 3/4" × 10 1/4".

Originally published in 1991 and out-of-print for some years, this work deserves broad distribution. As plants have been exported from one continent to another so have many of their pests, particularly arthropods. While the author, a professional entomologist, writes of species commonly found in the United Kingdom, he notes throughout those holarctic species also found in North America (and elsewhere) and those introduced into North America from other areas. Each pest species is described: the various stages of its life cycle and the damage it does to specific plants. Color photographs lead to certain identification. The author's suggested controls are not exclusively general or systemic insecticides; often he notes that damage is minimal and control unnecessary. Good management and biological controls are also emphasized. Most useful may be the extensive coverage of those most trouble some homopterans (psyllids, aphids, aegilids, thrips, scales) and mites. Affected plants are indexed by common and by scientific names. This book should serve as a standard reference for serious gardeners, horticulturists, and silvaculturists.—*Joann Karges, Botanical Research Institute of Texas, Fort Worth, TX, U.S.A.*

ABSTRACT

Five new combinations are proposed in the genus *Polygonum* s. str. for the forthcoming treatment of Flora of North America: *P. aviculare* subsp. *buxiforme*, *P. fowleri* subsp. *hudsonianum*, *P. humifusum* subsp. *caurianum*, *P. ramosissimum* subsp. *prolificum* and *P. striatulum* var. *texense*. The taxonomy of each taxon is briefly discussed and a diagnostic table is provided for the subspecies of *Polygonum aviculare*.

RESUMEN

Se proponen cinco nuevas combinaciones en el género *Polygonum* para el futuro tratamiento de este género en la Flora de Norteamérica: *P. aviculare* subsp. *buxiforme*, *P. fowleri* subsp. *hudsonianum*, *P. humifusum* subsp. *caurianum*, *P. ramosissimum* subsp. *prolificum* y *P. striatulum* var. *texense*. La taxonomía de cada taxon se discute brevemente y se incluye una tabla diagnóstica para las subespecies de *Polygonum aviculare*.

INTRODUCTION

During the preparation of *Polygonum* s. str. for Flora of North America it was concluded that several new combinations are required to reflect the new taxonomic knowledge in this genus. The changes involve *P. buxiforme* Small, *P. hudsonianum* (Wolf & McNeill) Hinds, *P. caurianum* Robinson, *P. prolificum* (Small) Robinson and *P. texense* M.C. Johnston.

1. Polygonum aviculare complex

Polygonum aviculare is a taxonomically controversial polyploid complex of predominantly selfing annuals. Lindman (1912) recognized two species: *P. heterophyllum* (= *P. aviculare* subsp. *aviculare*) and *P. aequale* (= *P. aviculare* subsp. *depressum*), while Chrtek (1956) accepted only one species, *P. aviculare*, with several subspecies. However, European and North American taxonomists have frequently recognized several distinct species within this complex: *P. aviculare* s.str., *P. arenastrum* Boreau, *P. boreale* Lange, *P. rurivagum* Jord. ex Boreau, *P. neglectum* Besser and *P. buxiforme* Small (e.g. Styles 1962; Mertens & Raven 1965; Scholz 1977; Wolf & McNeill 1986). The recognition of the former four species has been mainly based on Styles (1962) who studied British popu-

[1]Corresponding author.

lations. Styles (1962) found these four species to be morphologically discontinuous and with different chromosome numbers: *P. aviculare* and *P. rurivagum* were hexaploids (2n = 60), while *P. boreale* and *P. arenastrum* were tetraploids (2n=40). Studies done in North America initially confirmed these observations and the recognition of these species relied heavily on these different chromosome numbers (e.g. Mertens & Raven 1965; Moore et al. 1970; McNeill 1981). More recent studies have challenged both the morphological and the cytological criteria. Multivariate analysis and isoenzyme studies using many populations have proved that these taxa are not well-differentiated and populations with intermediate characteristics may occur (Meerts et al. 1990). Other chromosome counts, obtained both in Europe and North America, reported hexaploid populations among *P. arenastrum* and tetraploids among *P. aviculare* (e.g. Gasquez et al. 1978; Wolf & McNeill 1987; Meerts et al. 1998). Isoenzyme studies showed that the *P. aviculare* complex has probably an allopolyploid origin (Meerts et al. 1998) and it has evolved as a swarm of inbreeding lines ("Jordanons") (Gasquez et al. 1978). Yurtseva (2001) suggested that the patterns of variation in the pericarp surface support the hybrid origin of some species. For example, *P. arenastrum* presumably originated as a hybrid between *P. aviculare* and *P. calcatum* (= *P. aviculare* subsp. *depressum* in this study). *Polygonum neglectum* resulted from the hybridization of *P. aviculare* and *P. arenastrum*. Although the members of *P. aviculare* are predominantly inbreeders, some structures that make possible cross-pollination in other Polygonaceae are present here as well. Cleistogamous and chasmogamous flowers, the heterostyly, protandry, and the capacity to secrete nectar may be regarded as remnants of an ancestral mixed mating system (Costea and Tardif, unpublished). Bugg et al. (1987), Yurtseva (1998) reported that flowers of *P. aviculare* agg. are frequently visited by insects and thus introgression may occur to some extent. This would explain the complex intermediate variation patterns that occur between its members. In such conditions, recognition of these taxa at species level is unrealistic and unpractical. The subspecific rank is proposed for *P. buxiforme* because of the intermediates observed mainly with *P. aviculare* subsp. *aviculare*.

Polygonum aviculare L. Sp. Pl.:359. 1753 subsp. **buxiforme** (Small) Costea & Tardif, comb. et stat. nov. (**Fig. 1.**). BASIONYM: *Polygonum buxiforme* Small, Bull. Torrey Bot. Club 33:56. 1906. *Polygonum littorale* auct., non Link; *Polygonum aviculare* var. *littorale* auct., non Mertens & Koch; TYPE: U.S.A. VIRGINIA. LEE CO.: about Cumberland Gap, 27 Jul 1892, *J.K. Small s.n.* (LECTOTYPE formally designated here, Katz & McNeill, in herb 1988, NY 323754!).

Polygonum buxiforme f. *montanum* Brenckle, Phytologia 3:363. 1950.

Polygonum aviculare includes at least six subspecies in North America, which are distinguished only by a combination of characters (Table 1). Some extensively employed characters may be misleading if not examined properly. Heterophylly has been considered by all authors an important feature that distinguishes for

FIG. 1. *Polygonum aviculare* subsp. *buxiforme*; the lectotype. (*J.K. Small s.n.* NY 323754.)

TABLE 1. Comparison between the subspecies of *Polygonum aviculare*. Mature early season plants with leaves, flowers and achenes are necessary for accurate determinations. Measurements of leaves and ochreas were made at the middle of main stem. Description of perianth refers to fruiting perianth, which was measured from the joint with the pedicel. Description of achene uses the terminology of Wolf and McNeill (1986).

Origin	Eurasia	Northwestern Europe, Greenland	North America	Europe	Eurasia	Europe
Distribution	frequent across all of North America	Greenland, rare in Labrador	frequent across all of North America	rare in North America (Costea & Tardif, in ed.)	across most of North America, but less frequent than ssp. *depressum*	common across all of North America
Ecology	weed in ruderal places and cultivated fields; more sensitive to drought and trampling tnan ssp. *depressum*	sea-shores in open sand, drift banks and rocky shores shores	weed in ruderal habitats or sometimes agrestal; nondrifting sands, borders of marshes and dunes	dry and sunny habitats; mostly ruderal growing in pavement cracks and gravel	growing in all types of ruderal and agrestal habitats	agrestal and ruderal in heavily trampled habitats; sometimes in turf or grazed grasslands

example subsp. *aviculare* (= *P. aviculare* s. str.) from the homophyllous taxa: subsp. *depressum* (= *P. arenastrum*) and subsp. *neglectum* (= *P. neglectum*). It was stated that heterophyllous plants have cauline leaves which are more than three times as long as the branch leaves, while homophyllous plants have stem and branch leaves of about the same size (e.g. Wolf & McNeill 1986). The ratio between the lengths of middle stem and branch leaves (Table 1) shows that using the above definitions, some plants of subsp. *aviculare* may be considered homophyllous, while some of the subsp. *depressum* and subsp. *neglectum* may be characterized as heterophyllous. Heterophylly is not always a clear cut character and it can be efficiently used by taking into account the mentioned ratios (Table 1). In other words, keeping in mind that some taxa are "more heterophyllous" than others. Another potential source of error is the morphology of the tepals. Cucullate tepals are said to be distinctive for North American taxa such as subsp. *buxiforme*. In contrast, the non-native taxa (e.g. subsp. *aviculare*) are said to possess flat tepals (Mitchell & Dean 1978). This is not true as subsp. *aviculare*, subsp. *neglectum* and often subsp. *depressum* may also exhibit cucullate tepals in fruit (Table 1).

2. Polygonum hudsonianum (Wolf & McNeill) Hinds

Wolf and McNeill (1986) described this taxon as a subspecies of *P. caurianum*. Later, Hinds (1995) observed that subsp. *hudsonianum* was clearly differentiated from *P. caurianum* and he raised the former to specific rank. However, the author noted that the "separation of *P. fowleri* and *P. hudsonianum* is [...] more difficult" (Hinds 1995). Indeed, intermediate plants may occur between the two taxa, making their identification problematic at times. Therefore, taking into account that *P. caurianum* is distinct from both (see below), we propose the classification of *P. hudsonianum* as a subspecies of *P. fowleri*:

Polygonum fowleri Robinson subsp. **hudsonianum** (Wolf & McNeill) Costea & Tardif, comb. nov. BASIONYM: *Polygonum caurianum* Robinson subsp. *hudsonianum* Wolf & McNeill, Rhodora 88:469. 1986. *Polygonum hudsonianum* (Wolf & McNeill) Hinds, Novon 5:165. 1995. TYPE: CANADA. QUÉBEC: Fort George, 30 Aug 1950, *E. Lepage 12863* (HOLOTYPE: DAO 539717!; ISOTYPE: QFA!).

3. Polygonum humifusum Merk ex Koch

Hultén (1968) observed that *P. caurianum* Robinson might be "closely related or identical" to *P. humifusum* Merck ex Koch from Siberia and Kamtschatka. The BONAP list (1998) explicitly considered the latter name as a nomenclatural synonym of the former. However, it must be noted that *P. humifusum* is the correct binomial because it has priority. This species has a unique feature: the lower leaves are often opposite, and Tzvelev (1979) even separated it in a distinct subsection - *Humifusa*. The closest North American species is *P. fowleri*, which may rarely (especially subsp. *hudsonianum*) have a few leaves that are opposite. For differences, see Hinds (1995). The comparison of Russian and North

American specimens of *P. humifusum* revealed morphological differences, which together with the disjunct geographical distribution allow the recognition of two subspecies:

Polygonum humifusum Merk ex Koch, Linnaea 22:205. 1849.

a. subsp. **humifusum**
Stems and leaves green. Perianth 1.5–2.0 mm, with ± erect tepals, green with white margins, only in some flowers with pink margins. Achene 2.1–2.7 mm, ± rostrate, the apex exserted 0.9–1.3 mm. 2n = 20. (Tzvelev 1979). Siberia and Kamtschatka.

b. subsp. **caurianum** (Robinson) Costea & Tardif, comb. et stat. nov. BASIONYM: *Polygonum caurianum* Robinson Proc. Bost. Soc. Nat. Hist. 31:264.1904. TYPE: U.S.A. ALASKA: Nushagak, 59° N 158° W, Aug 1882, *C.L. McKay s.n.* (HOLOTYPE: GH 32603!).

Stems and leaves reddish or purplish tinged (if leaves are green, at least the margins are reddish or purplish). Perianth 1.5–2.3(–3) mm, with ± outcurved tepals, green or purple with the margins pink to purple. Achene 1.4–1.6(–2.2) mm, not or obscurely beaked, with the apex exserted 0.1–0.5 mm. Chromosome number unknown. NW Alaska, Yukon and NW Territories.

4. Polygonum prolificum (Small) B.L. Robinson

Polygonum prolificum was originally described by Small (1894) as a variety of *P. ramosissimum*, and later it was raised to species rank by Robinson (1902). Mitchell and Dean (1978) mentioned that the specimens of the two taxa "show too much intergradation to be separated with satisfaction" and we confirm their findings. The subspecific rank is proposed for *P. prolificum*.

Polygonum ramossisimum Michx. subsp. **prolificum** (Small) Costea & Tardif, comb. et stat. nov. BASIONYM: *Polygonum ramossisimum* Michx var. *prolificum* Small, Bull. Torrey Bot. Club 21:171. 1894. *Polygonum prolificum* (Small) Robinson, Rhodora 4:68. 1902. TYPE: U.S.A. NEBRASKA: Exeter, *J.H. Wibbe s.n.* (HOLOTYPE: NY 323808!).

Polygonum prolificum var. *autumnale* Brenckle, Phytologia 2:404. 1948
Polygonum prolificum var. *profusum* Brenckle, Phytologia 2:404. 1948.

For differences between the two taxa see Mitchell and Dean (1978) and Wolf and McNeill (1986). Subsp. *prolificum* is less variable and less common than subsp. *ramossisimum*, growing mostly in wet, saline places, which are scattered across all of North America.

5. Polygonum texense M.C. Johnston

Recently, *P. texense* has been considered a synonym of *P. striatulum* (BONAP 1998; Hatch et al. 2002). Although the morphology of the flowers and fruits is very similar, the two perennial taxa are distinct on the basis of their leaf morphology and their different phenology and ecology. The varietal rank is proposed here for *P. texense*:

Polygonum striatulum Robinson var. **texense** (M.C. Johnston) Costea & Tardif, comb. et stat. nov. BASIONYM: *Polygonum texense* M.C. Johnston, Southw. Naturalist 14:257. 1969. TYPE: U.S.A. TEXAS, *J. Scudday* s.n. (HOLOTYPE: LL.; ISOTYPE: LL!)

For morphological differences between var. *striatulum* and var. *texense* see Correll and Johnston (1970). Plants of var. *striatulum* grow in eastern and southeastern Texas, while plants of var. *texense* occur in central-western Texas and southeastern New Mexico.

ACKNOWLEDGMENTS

The authors thank John McNeill and Guy Nesom for their prompt and most helpful suggestions on the manuscript. We also thank curators from ACAD, ALTA, CAS, DAO, DC, DS, GH, F, JEPS, LL, MT, MTMG, NFLD, NSPM, NY, PO, QFA, QUE, RSA, SASK, TEX, UBC, UC and US for preparing the (usually) voluminous loans.

BOOK NOTICE

CHARLES B. HEISER. 2003. **Weeds in My Garden: Observations on Some Misunderstood Plants.** (ISBN 0-88192-562-4, hbk.). Timber Press, Inc., 133 S.W. Second Avenue, Suite 450, Portland, OR 97204-3527, U.S.A. (Orders: www.timberpress.com, 800-327-5680, 503-227-2878, 503-227-3070 fax). $22.95, 260 pp., 29 color photos, 30 line drawings, 5 1/2" × 8".

From the dust jacket: "Weeds, by their nature, get around. This book treats about 140 weeds, and more than half of these may be found throughout most of North America. Many were originally native to eastern North America, and others first came from Eurasia. The author chooses weeds that have found their way into "his garden," the Botany Experimental Field at Indiana University where he has grown plants for more than half a century."

Reading through Heiser's wonderful book on weeds brought back pleasant childhood memories. For I know weeds from a different kind of "garden," my dad's cotton field in southwestern Oklahoma. Dad was a cotton farmer and a good one at that. Being born during cotton harvest time (in the fall) in the middle of the 20th century, mother tells me I made my first trip to a cotton field at the early age of a few days to one week. It was there in those cotton fields back home where I had my first and up close encounters with plants, albeit cotton plants. I didn't do any collecting (not that I remember) except for lots of sleep in the shade of the cotton wagon. I occasionally took a ride down the cotton rows on the top of mother's cotton sack. By the time cotton is ready to harvest most of the weeds have been pretty much eliminated from the "garden" by either a cultivator or by a hoe. As I got older I discovered weeds through "chopping cotton" with a hoe, and it didn't take long to learn that "chopping cotton," meant chopping weeds. Dad taught me—early in life—my first lessons in identifying plants (weeds). Positive "identification" of cotton field "weeds" was of the utmost importance; dad made sure of that, for "chopping cotton" was all about weed identification ... that is, all of the "unwanted" plants growing sometimes intimately with those beautiful cotton plants. What is a weed? For me it was any plant but cotton?—*Barney Lipscomb, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX 76102-4060, U.S.A., barney@brit.org.*

ABSTRACT

We describe in this paper the hybrid genus ×*Taxodiomeria* Z.J. Ye, J.J. Zhang et S.H. Pan, gen. nov. (*Taxodium* Rich. × *Cryptomeria* D. Don) and the hybrid species ×*T. peizhongii* Z.J. Ye, J.J. Zhang et S.H. Pan, sp. nov. (*Taxodium mucronatum* Ten. × *Cryptomeria fortunei* Hooibrenk ex Otto et Dietr.) (Taxodiaceae). The hybrid originated in Nanjing in 1963 and was introduced into Shanghai in 1975; it has been propagated vegetatively since then. These hybrids, about 2000 in all, were hardly known but are now big trees and highly valued for their fine shape, faster growth rate, and adaptation to urban environments compared to *Taxodium* and *Metasequoia*. Morphologically, the hybrid species strongly resembles *Taxodium mucronatum*, differing slightly in a few vegetative characteristics.

ABSTRACT (CHINESE)

本文对杂交属 *Taxodiomeria* Z.J. Ye, J.J. Zhang et S.H. Pan, gen. nov. (*Taxodium* Rich. × *Cryptomeria* D. Don) 和杂交种 *T. peizhongii* Z.J. Ye, J.J. Zhang et S.H. Pan, sp. nov. (*Taxodium mucronatum* Ten. × *Cryptomeria fortunei* Hooibrenk ex Otto et Dietr.) (Taxodiaceae) 作了描述。该杂种 1963 年在南京杂交成功，1975 年引入上海，并进行无性繁殖，现有大树约 2000 株。这些杂种过去鲜为人知，但如今因其树形美观，生长速度快于落羽杉属（*Taxodium*）和水杉属（*Metasequoia*）树种且更能适应城市环境，而受到高度重视。该杂种在形态上与墨西哥落羽杉（*Taxodium mucronatum*）很相似，但在一些营养体特征上与后者有差异。

A new intergeneric hybrid *Taxodiomeria peizhongii* Z.J. Ye, J.J. Zhang et S.H. Pan of Taxodiaceae, described below, arose from a cross between *Taxodium mucronatum* Ten. (♀) and *Cryptomeria fortunei* Hooibrenk ex Otto et Dietr. (♂). It is said that a number of individuals of *Taxodium mucronatum* were introduced into China around 1925, but now only two were found living. One was on the campus of Dongnan University of Nanjing, the maternal plant of the hybrid species. *Cryptomeria fortunei*, a native of southeastern China, is widely

[1] Authors for correspondence: Zhang Jian-Jun, zjjun071416@yahoo.com.cn; Hsu Ping-Sheng, pshsu@fudan.edu.cn.

cultivated in the area south of the Yangtze River, but the paternal tree of the hybrids has not been found. The hybrid cross was made in Nanjing in 1963 by the late Prof. Ye Pei-Zhong, a prominent botanist specializing in the cross-breeding of trees. Finally he was able to produce three cones and a number of hybrid seedlings, but only five of the 12 F_1 seedlings survived (Anonymous 1979; Miao et al. 1982). About 6000 cuttings were prepared in successive years up until 1972. Some of these were introduced to Shanghai, Hangzhou, Wuhan, and other cities in China. It seems that the hybrid saplings had not shown any valuable silvicultural characteristics superior to the related species of *Taxodium*, *Metasequoia*, and *Cryptomeria*. Therefore, they did not excite much interest among dendrologists in Nanjing. This is probably why there are only a limited number of hybrid trees growing there today.

Some 260 hybrid saplings were introduced into Shanghai for the first time in 1975 under the supervision of professors Cheng Xu-Ke and Jin Guo-Pei. From 1975 to 1983, thousands of young plants were propagated vegetatively from these saplings in the tree nurseries of Songjiang and Yangjing while Ye Zheng-Ji, the fifth author of this paper, was in charge of the work of cultivation and propagation of the hybrids in Songjiang. However, for lack of sufficient knowledge as to the merits and potentialities of the hybrid trees and also for some other reasons, the number of trees gradually decreased; these were hardly known to the public until the end of the 1990s.

The discovery of the hybrids was the result of a survey for tree resources of Shanghai carried out by Ye Zheng-Ji and his colleagues from 1998 to 2001. They have found that the 20–30 year-old F_1 hybrids—about 2000 in all—have proven to be very successful in Shanghai compared to *Taxodium distichum* (L.) Rich., *T. ascendens* Brongn., *Metasequoia glyptostroboides* Hu et Cheng, and *Cryptomeria fortunei* Hooibrenk ex Otto et Dietr. These hybrids are semi-evergreen, grow fast, hold up to strong winds, and thrive not only in ordinary garden soil but also in wetlands and saline sea-shores with a soil pH ranging from 6.5 to 8.6. The trees can grow in saline soil with 0.4% salt. A small plantation of the hybrids was seen growing well in a lake in Songjiang. These data are congruent with the statements that hybrids sometimes respond better than their parents (Stebbins 1969) and that they may show new characters not present in either parent (Knobloch 1972). The stand of hybrids in Chuansha Tree Nursery, the largest one in Shanghai—with about 1500 individuals covering an area of about 1.8 ha.—was designated "The Protected Forest of Germplasm Resources of Shanghai" by the municipal authorities in 2001. These trees are 30–40 cm. in diameter at breast-height, and the largest is about 62.5 cm. in diameter. The hybrid species is useful for landscape planting as well as for large-scale windbreaks in the riverine and coastal regions of Shanghai and neighboring provinces. Since the climatic and edaphic conditions (the more or less alkaline soil and the high groundwater level) in Shanghai are not very favorable for growing many kinds

of trees, these new hybrids are bound to play an important role in the rapid development of gardening and urban forestry in the city.

×**Taxodiomeria peizhongii** Z.J. Ye, J.J. Zhang et S.H. Pan, gen. et sp. nov. (**Figs. 12, 13**). *Taxodium mucronatum* Ten. (♀) and *Cryptomeria fortunei* Hooibrenk ex Otto et Dietr. (♂). TYPE: CHINA. SHANGHAI: Jinshan, Jinshan General Petrochemical Works, cultivated tree more than 20 m high, diameter breast-height ca. 50 cm, bearing juvenile male strobili, strips of bark transversely fissured, 25 Sep 2001, *S.H. Pan 01563A* (HOLOTYPE: PE; ISOTYPES: NAS, SHM).

Haec species hybrida speciei materno *Taxodio mucronato* Ten. valde similis, a quo praecipue differt planta ut in specie paterno sine geniculis et anteridibus etiam crescenti in terra humida, trunco integro nec dilatato ad basin et plerumque in summo altitudinem 5–8 metrorum duobus pluribusve ramulis primariis diviso raro recto et simplice, corticis schedis longis angustisque saepe transversaliter fissuratis tecto, et surculis multis in ramulis primariis vel etiam in trunco instructa. Strobili a nobis non visi praeter plantis singulis ex Jinshanensi in autumnum amentis masc. immaturis 6–12 cm longis secus ramulos hornotinos dispositis paniculam pendulam formantibus instructis. Strobili masc. immaturi unusquisque 6 staminibus praediti.

In cultura in solo usitato horti et in terris humidis et etiam in littoribus salsis.

PARATYPE: **CHINA. Shanghai:** Songjiang, Zuibaichi Park, cultivated, 21 Sep 2001, *S.H. Pan 01540* (SHM); Pudong, Yangjing Nursery, cultivated, in flooded ground, 12 Aug 2001, *S.H. Pan 01275A* (FUS); Shanghai, Pudong, Chuansha Tree Nursery, in a stand along the coast, 1 Sep 2001, *S.H. Pan 01400* (SHM).

The specific epithet *peizhongii* honors Prof. Ye Pei-Zhong of the former Nanjing Forestry College, who made this hybrid by crossing *Taxodium mucronatum* (♀) and *Cryptomeria fortunei* (♂).

This hybrid species resembles the maternal species *Taxodium mucronatum* Ten. in the spirally arranged, drooping, annual leafy shoots that drop shortly before the new shoots leaf out in spring and in having closely arranged, distichous, short (<1cm long) leaves (Fig. 11). The phenomenon of matro-clinal inheritance of the hybrids has recently been confirmed by RAPD analysis (Chen et al. 2002). This report has shown that the genetic distance of the hybrids from *T. mucronatum* (0.210–0.246) is much shorter than that of the hybrids from *Cryptomeria fortunei*, their paternal species (0.757–0.764). Morphologically, the hybrid differs from the maternal species chiefly in a few significant characters. It does not have butswells (knee-like growths) and buttresses (as in the paternal species), the trunk is usually divided at a height of 5–8 m into two or more primary branches and, consequently, the crown has forms such as conical, cylindric, ellipsoid, and pyriform, etc., all of them being more or less round-topped. Rarely is the trunk straight and undivided. The narrow, long strips of bark are usually transversely fissured. There are many shoots on the primary branches or even on the trunk.

Buttresses and butswells are characteristic of the genus *Taxodium* (Harrison 1966; Hart & Price 1990), though butswells are only occasionally seen in *T. mucronatum* (Hart & Price 1990; Martinez 1950), and their presence depends to a great extent on the environmental conditions in which the plants grow (Kurz

& Demaree 1934). In the present hybrid species, however, the trunk is integral and buttresses and butswells have never been seen even in plants growing either in wetlands or in seasonally flooded lowlands. Thus, it can be seen that there is a difference between the hybrid species and *Taxodium mucronatum* concerning the presence or absence of butswells or buttresses.

It seems that different tree forms have something to do with age in *Taxodium*, from columnar, to more conical, and to flat topped (J. Li, pers. comm. 2001). The hybrid trees are of conical habit when young but develop a wide and often flattened crown when old (Harrison 1966; Hart & Price 1990). But no matter how great the variation of the tree forms may be, the trees maintain their straight trunks and do not form double multiple leaders as do most of our hybrid trees.

Although the hybrids generally have no strobili, at least now, some individuals cultivated in Jinshan have been found to bear male catkins 6–12 cm long assembled into pendulous panicles on the present year's shoots in autumn [2002]. These immature male strobili possess six microsporophylls each and are expected to open in spring 2003.

KEY TO VEGETATIVE DIFFERENCES BETWEEN ×*TAXODIOMERIA PEIZHONGII* AND *TAXODIUM MUCRONATUM*

1. Base (trunks) of adult trees in either wetlands or in saline soil without buttresses (Fig. 1), butswells (knee-like growths) absent; long narrow strips of bark usually transversely fissured (Figs. 4, 5); tree usually divided at a height of 5–8 m into 2 or more primary branches (Figs. 6, 7, 8); crown with many different forms, conical, cylindric, ellipsoid, pyriform, etc.—but with more or less a rounded top (Figs. 9, 10) _____ **×Taxodiomeria peizhongii**

1. Base (trunks) of adult trees always with a swollen and often buttressed bases (Figs. 2, 3), butswells (knee-like growths) frequently present in flooded areas; long narrow strips of bark never transversely fissured; tree conical in habit when young, but developing a wide and often flattened crown when old _____ **Taxodium mucronatum**

ACKNOWLEDGMENTS

We thank Li Jian-Hua and Peter Del Tredici of the Arnold Arboretum of Harvard University for their helpful suggestions and for sending us needed literature; Verne Grant, Barney L. Lipscomb, and John W. Thieret for offering suggestions for improvement; and Prof. Ni De-Xiang of Fudan University for his participation in our investigation and helpful comments.

ABSTRACT

A new species of *Dioscorea*, *D. lisae* Dorr & Stergios, is described and illustrated. Relationships, distinguishing characters, and sex distribution are discussed. Information also is provided on the ecology and geographical distribution of this new species.

KEY WORDS: Dioscoreaceae, *Dioscorea*, Venezuela, Andes

RESUMEN

Se describe y se ilustra una nueva especie de *Dioscorea*, *D. lisae* Dorr & Stergios. Se discuten las relaciones, caracteres particulares y la distribución del sexo. Además, se presenta información de la ecología y distribución geográfica de esta especie nueva.

PALABRAS CLAVES: Dioscoreaceae, *Dioscorea*, Venezuela, Andes

Four species of *Dioscorea* L. (Dioscoreaceae) have been collected in Guaramacal National Park, which protects an area of ca. 200 km^2 of montane forest, cloud forest, and páramo near the northern end of the Cordillera de Mérida in Portuguesa and Trujillo states, Venezuela (Dorr et al. 2000). Two of the species, *D. lehmannii* Uline and *D. meridensis* Kunth, are well-circumscribed although infrequently collected and with wide ranges in the Andes, extending south to Ecuador and Peru. When we published a catalogue of the vascular plants of Guaramacal, we had not yet identified two of the four species, and we listed them as *Dioscorea* sp. A and *Dioscorea* sp. B (Dorr et al. 2000). The latter appears to be *D. coriacea* Humb. & Bonpl. ex Willd., a variable species with a number of synonyms and an extensive range in the Andes (Colombia and Venezuela to Bolivia). The former, however, cannot be associated with any known species and is described here as new.

Dioscorea lisae Dorr & Stergios, sp. nov. (**Figs. 1–2**). TYPE: VENEZUELA. TRUJILLO: Mpio. Boconó, Parque Nacional Guaramacal, road from Boconó to Guaramacal, SE of Boconó, N slope of mountain, 09°13'N, 070°12'W, 2000 m, 13 Jul 1995 (♂, ♀, fls), *Dorr & Barnett 8057* (HOLOTYPE: PORT; ISOTYPES: MEXU, US).

Species *Dioscorea coriacea* affinis, a qua imprimis differt tereticaulibus, pedicellis longioribus et foliis 5–7-nervis.

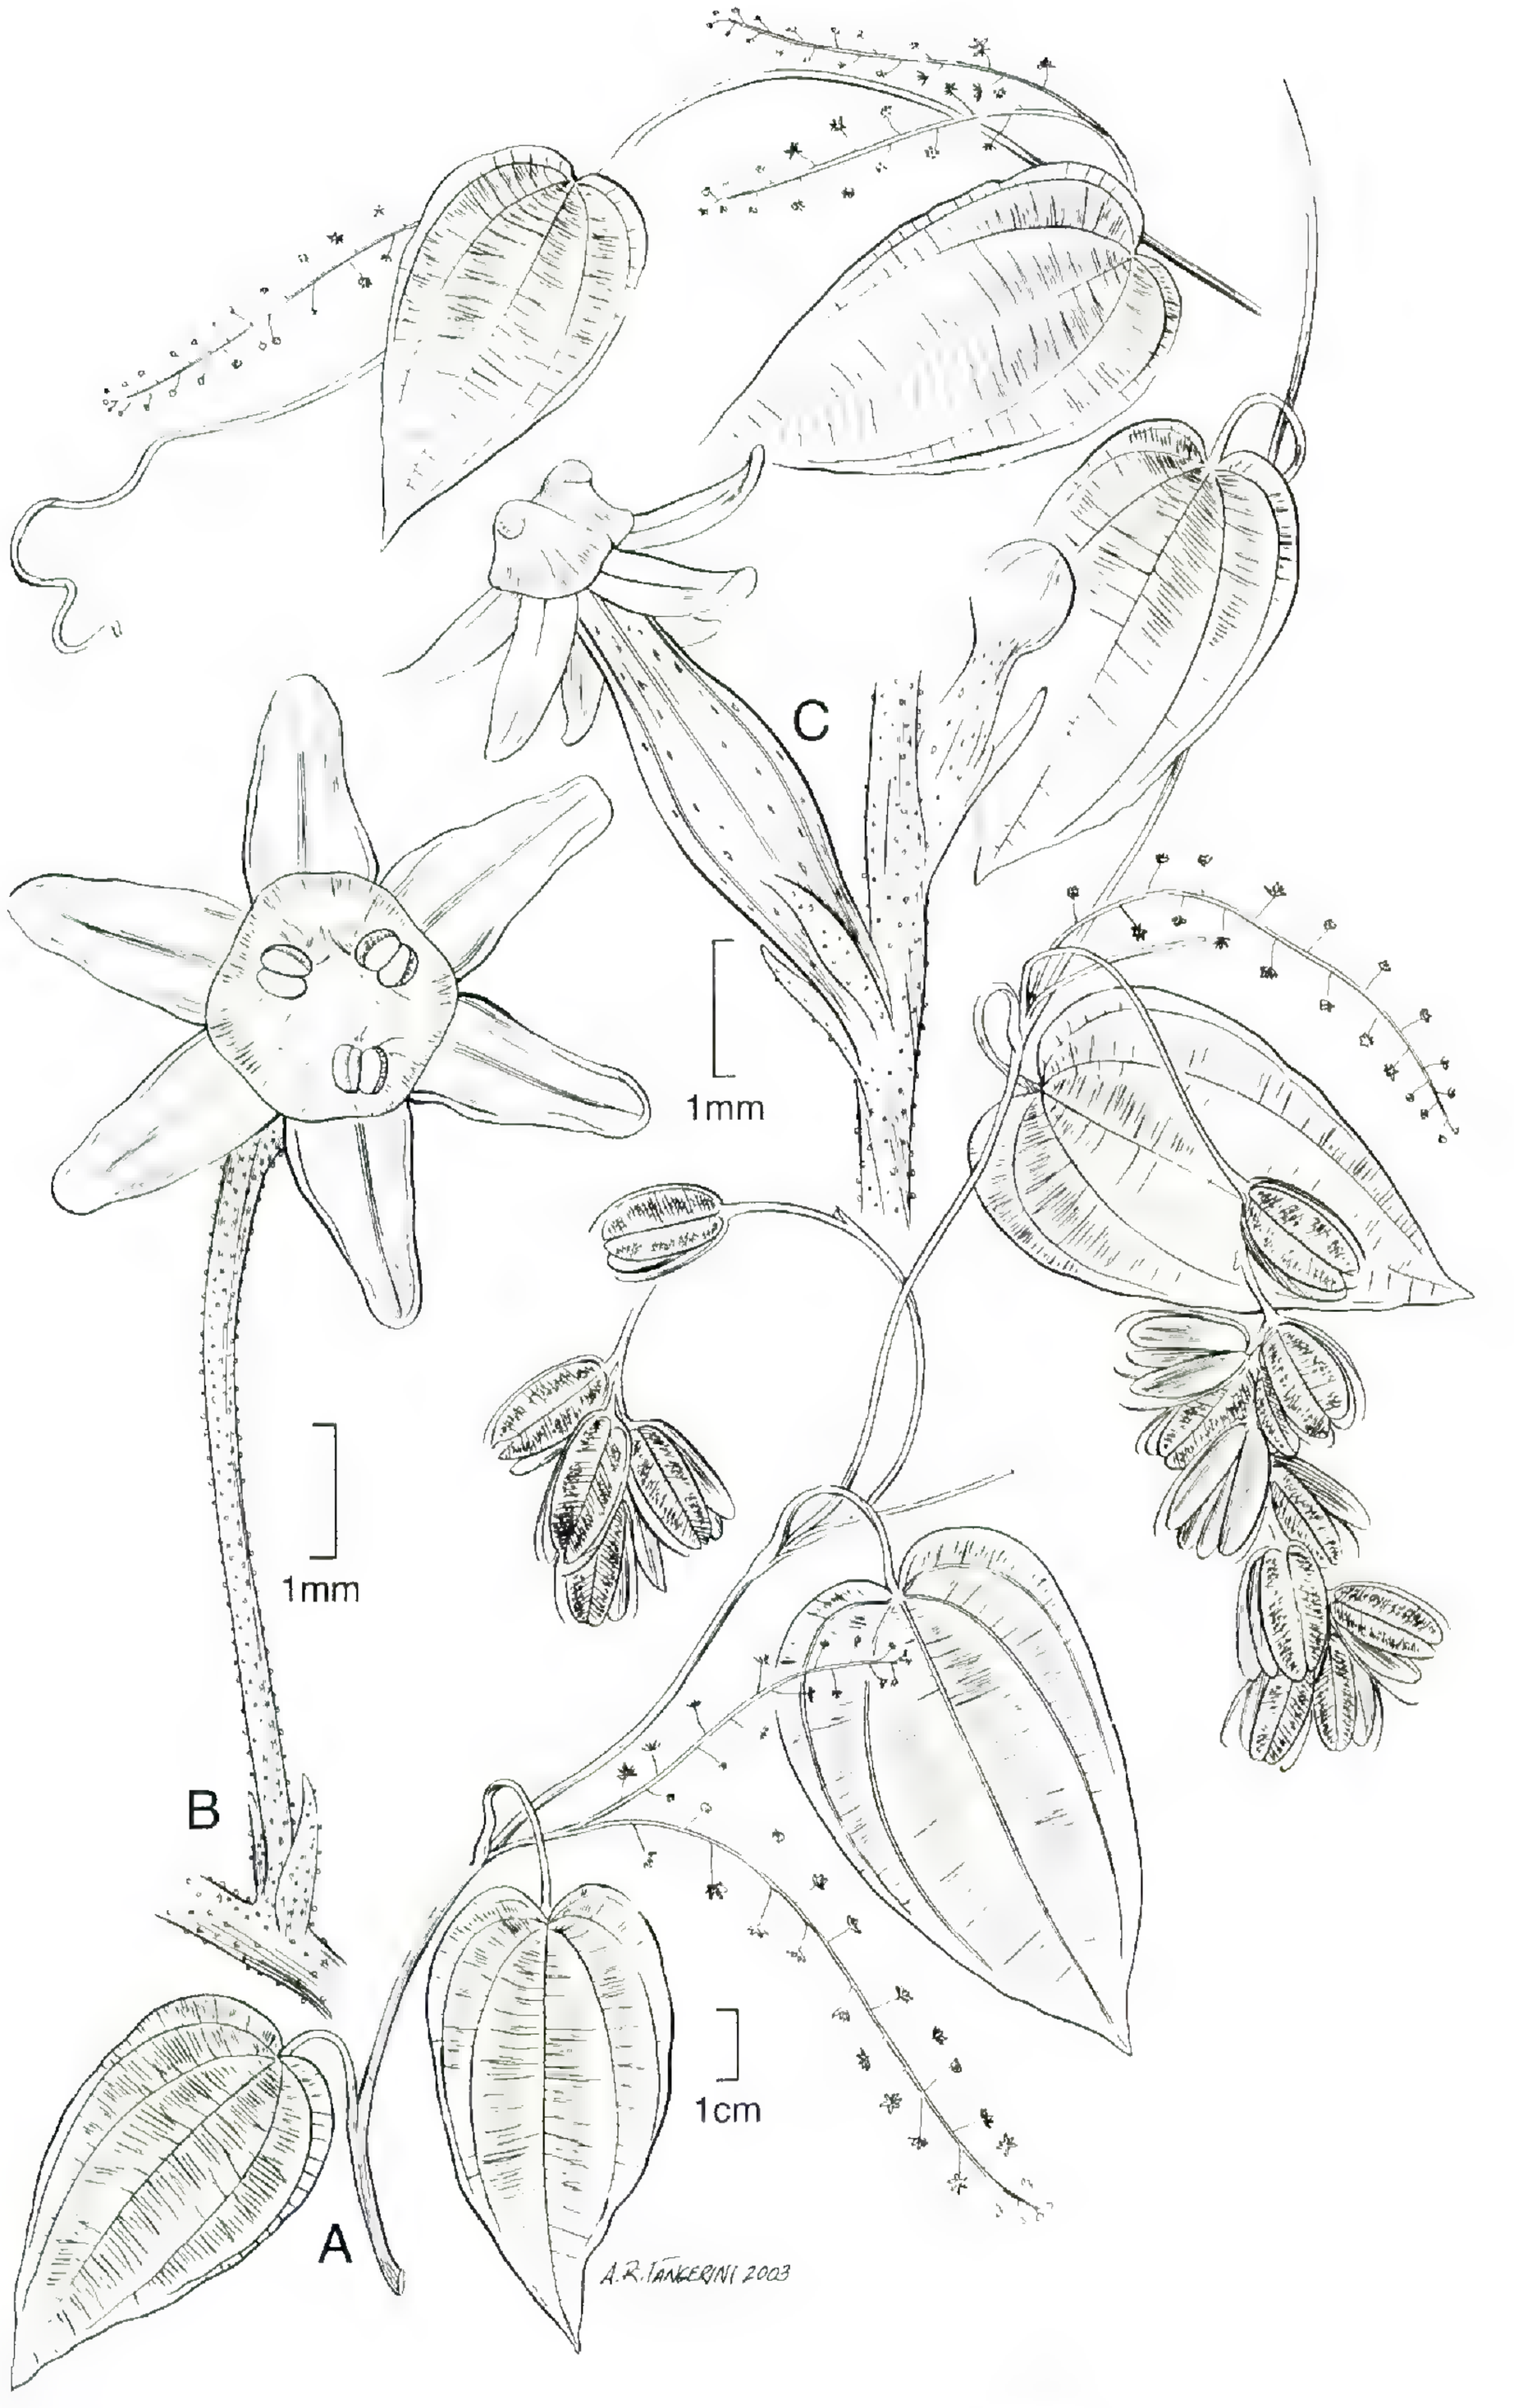

FIG. 1. *Dioscorea lisae* Dorr & Stergios. A. Habit (of a plant with mixed inflorescences, either male inflorescences or male inflorescences arising from the axils of infructescences). B. Staminate flower. C. Pistillate flower. (A, *Dorr et al. 8921*, US; B, *Dorr & Barnett 8057*, PORT; C, *Dorr & Barnett 8057*, MEXU).

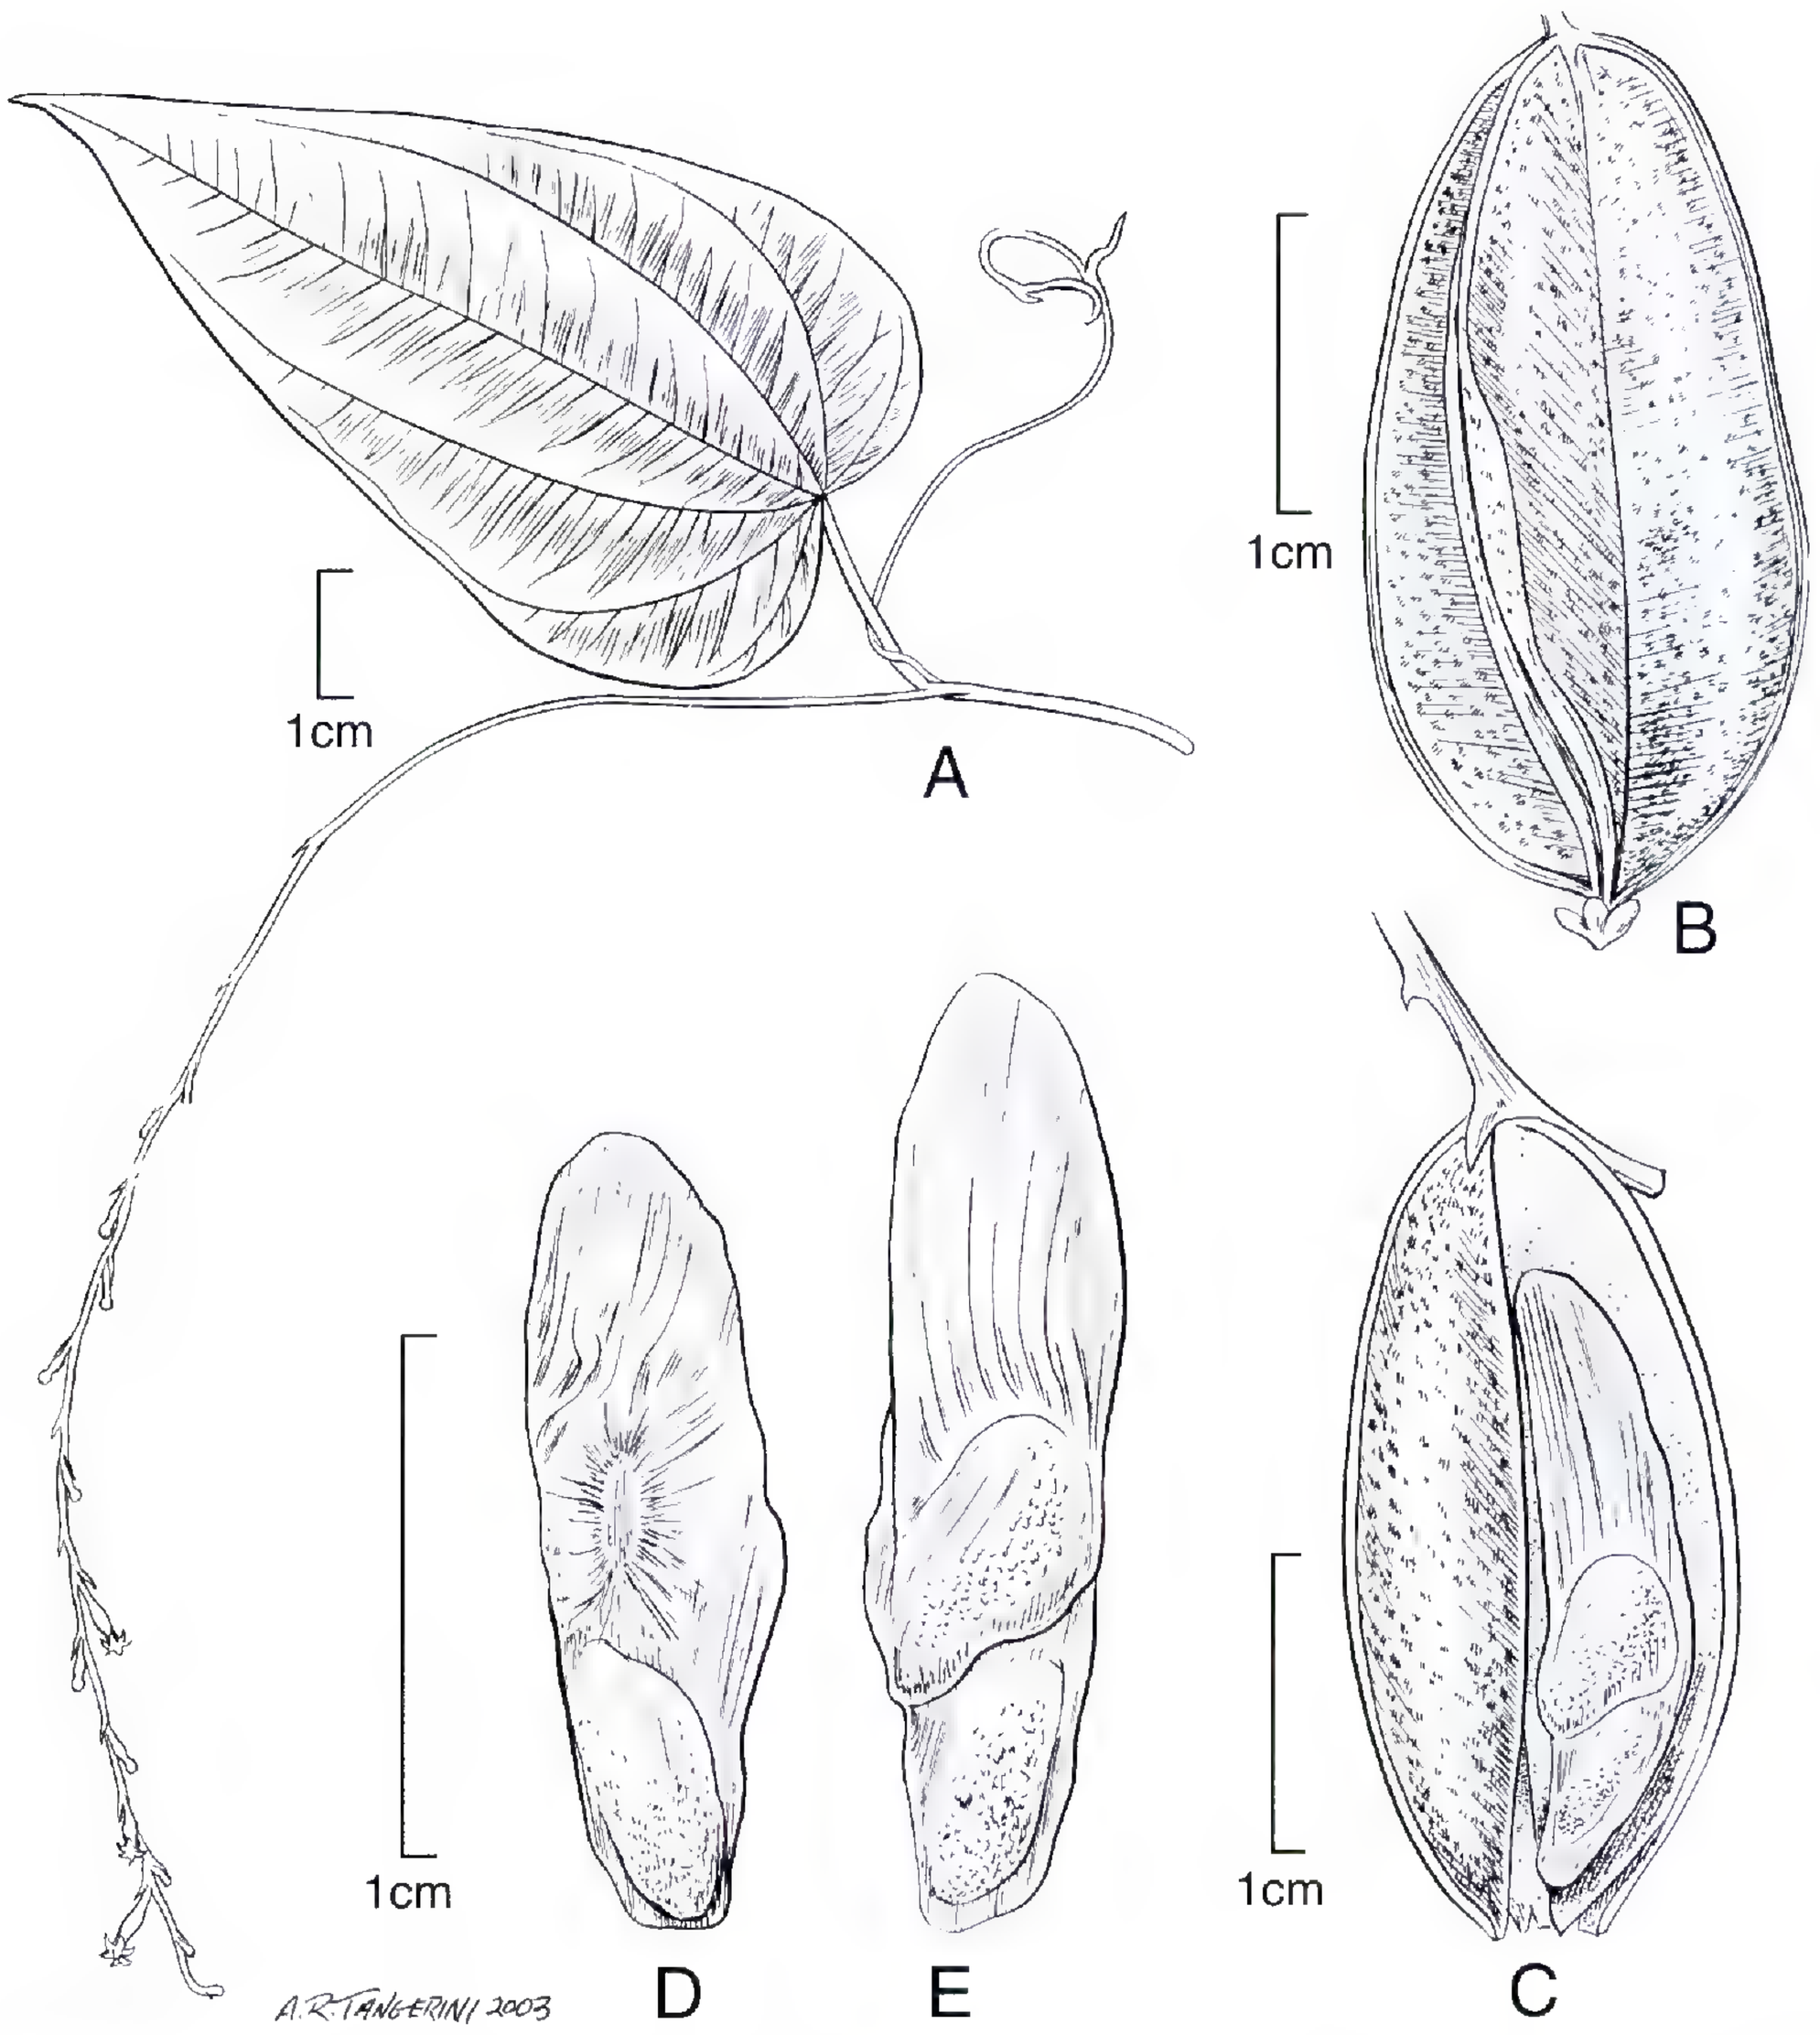

FIG. 2. *Dioscorea lisae* Dorr & Stergios. A. Female inflorescence. B. Capsule. C. Capsule, part of fruit wall removed to show orientation of seeds and seed wings. D, E. Seeds. (A, *Dorr et al. 8057*, US; B–E, *Stergios et al. 17034*, US).

Herbaceous twining vines; dioecious (or monoecious, with staminate inflorescences found on pistillate plants in fruit). Stems delicate, terete, twisting to the right (dextrorse), glabrous. Leaves alternate, entire. Leaf blades ovate-lanceolate, 7–11 × 3.2–5 cm, 5–7-nerved, the base cordate to truncate, the apex acuminate to long-acuminate, glabrous, membranous; petioles 1.5–3.5 cm long, glabrous, faintly glandular-dotted below. Staminate inflorescences paniculate, pendent, 8-13 cm long, with 1–4 racemose branches, flowers solitary, the rachis minutely-papillate, delicate; each flower subtended by a pair of unequal, acicular bracteoles, ca. 1–1.25 mm long; pedicels 5–8 mm long, minutely-papillate to

smooth. Staminate flowers greenish-red (*Licata & Cuello 217*) to purple (*van der Werff & Ortega 6066*), rotate at anthesis, the tepals equal, distinct, 1.25–1.5 × 0.75 mm, lanceolate, glabrous; stamens 3, borne on a flattened, annular disc, filaments very short, ca. 0.25 mm tall, thickened, anther cells ovoid, free (or connivent), introrsely dehiscent; staminodia absent. Pistillate inflorescences spicate, pendent, to 14 cm long, solitary; each flower subtended by a pair of unequal, acicular bracteoles ca. 1.5–1.75 mm long. Pistillate flowers with tepals equal, distinct, ca. 1–1.25 × 0.5 mm, lanceolate, glabrous; styles 3, fused at the base and free towards the apical stigmatic surfaces; staminodia absent. Capsules 2–3 × 1.2–1.4 cm, elliptic, the apex and base rounded, flattened, green (drying light brown) with dark, elliptic maculations, glabrous; seeds 2 per locule, ca. 0.5 × 0.5 cm, irregularly lenticular to ovate-lenticular, compressed, winged dorsally, the wing to 1 cm long, membranous.

PARATYPES. **VENEZUELA. Trujillo:** Mpio. Boconó, Parque Nacional Guaramacal, vertiente norte, subiendo por la Laguna Negra, 2620 m, Jun 2002 (♂ fls, fr), *Cuello 2433* (PORT); Parque Nacional Guaramacal, road from Boconó to Guaramacal, SE of Boconó and just above park headquarters, N slope of mountain, 09° 13'N, 070° 12'W, 5 Jul 1995 (♂ fls), *Dorr et al. 7981* (NY, PORT, US); Parque Nacional Guaramacal, road from Boconó to Guaramacal, SE of Boconó, N slope of mountain (09° 13'N, 070° 12'W), 29 Oct 1998 (♂, ♀, fls), *Dorr et al. 8381* (PORT, US); Parque Nacional Guaramacal, trail from El Cafenol (E of Mosquey) to Fila Los Recostaderos, 1790–2200 m, 12 Jun 2001 (♂, ♀, fls), *Dorr et al. 8896* (PORT, US), Ibid (♂ fls, fr), *Dorr et al. 8921* (PORT, US); Parque Nacional Guaramacal, en la vertiente norte, 09° 25'7"N, 070° 13'34"W, 1950 m, 4 Jun 1995 (♂ fls), *Licata & Cuello 217* (PORT-unicate); Parque Nacional Guaramacal, sector vertiente sur, carretera al caserío Guaramacal, 2000–2750 m, Feb 1997 (fr), *Stergios et al. 17034* (PORT, US); entre Boconó y Guaramacal, 2100–2300 m, 4 Sep 1966 (♂ fls), *Steyermark & Rabe 97309* (US, VEN); near Boconó, Páramo de Guaramacal, 09° 14'N, 070° 11'W, 2600–3100 m, 22 Nov 1984 (♂ fls), *van der Werff & Ortega 6066* (MO, PORT).

Distribution and ecology.—*Dioscorea lisae* is presently known only from the Ramal de Guaramacal in Trujillo state, Venezuela. This ridge is a 40 km long offshoot of the more extensive Cordillera de Mérida, which extends 325 km from Táchira to Lara. All but one of the collections we examined are from the north slope (mostly Qda. Segovia) of the Cerro de Guaramacal; the sole exception is a collection from the south slope (Qda. Jirajara) of the same mountain. *Dioscorea lisae* has been collected in montane and upper-montane forest; 1790–2750 (–3100) m. Flowering June, July, September, and November; fruiting February.

The US sheet of *Steyermark & Rabe 97309* is mislabeled with a locality in Táchira and the date 27 August 1966. Bono (1996: 526) also reported this collection (as *Dioscorea coriacea*) from Táchira, which suggests other duplicates may be mislabeled. Steyermark's field notes are unambiguous about the fact that he and Marvin Rabe collected a *Dioscorea* in Guaramacal on 4 September 1966 and that the collection was numbered 97309. Since all of the data on the labels used by Steyermark are printed save for the collection number and determination, which are typed, it is easy to imagine a typist grabbing one or more labels from the wrong stack when preparing the distribution of duplicate sheets.

Etymology.—The epithet honors Lisa Ceryle Barnett, botanist, science administrator, and wife of LJD. She has participated in many collecting trips to Guaramacal as well as numerous other expeditions by foot, mule, horse, or jeep to remote forests and páramos in the Venezuelan Andes.

DISCUSSION

Following the classification of Knuth (1924), *Dioscorea lisae* belongs in subg. *Helmia* (Knuth) Benth.; the ovules are attached near the distal (stylar) end of the ovary and the wing is developed unilaterally toward the proximal end (i.e., toward the base of the capsule). Several characters, including the presence in male flowers of a large glandular disc (not always readily apparent) and racemose male inflorescence branches with solitary flowers that have 3 anthers and lack staminodia, suggest a placement in sect. *Cycladenium* Uline of Knuth's (1924) scheme. In Huber's (1998) classification, *D. lisae* keys to sect. *Trigonobasis* Uline of Mexico and Central America, which he also associates with sect. *Cycladenium*.

Dioscorea lisae differs from other species in sect. *Cycladenium* in that its male flowers have very long pedicels, which greatly exceed the bracteoles in length, and its female flowers produce relatively large capsules, which have rounded (versus acute) apices and bases. As noted above, at least one of the specimens (*Steyermark & Rabe 97309*) we refer to *D. lisae* was misidentified earlier as *D. coriacea*, but *D. lisae* differs from that species in a number of morphological characters summarized in Table 1.

Dioscorea lisae apparently is not strictly dioecious. One of our collections (*Dorr et al. 8921*, US) has fruit and male inflorescences and it would appear that the sexes are separated temporally. In this case the male inflorescences evidently arise well after the female inflorescences have produced flowers and set fruit. Condon and Gilbert (1988, 1990) discuss what might be an analogous situation in the Cucurbitaceae. The genera *Gurania* (Schltdl.) Cogn. and *Psiguria* Arn., both neotropical vines that were long thought to be dioecious, are actually monoecious and only temporally dioecious. They documented that these genera have size-related and intra-seasonal sex changes. They also discovered strongly male-biased sex ratios. Our limited sample size (ten collections) hints at a male-biased sex ratio in *D. lisae*; nine collections have male flowers and six have female flowers and/or fruit. Nonetheless, the exact nature of sex expression in this species and factors controlling the same are not at all clear and will not be resolved with herbarium specimens alone.

While *Dioscorea* is almost universally considered to be dioecious, there are a number of other reports, usually dismissed, that this is not true of all species. Burkill (1960: 327) summarized the prevailing view by stating categorically "to date we do not have a single proved case of the two sexes being fertile on the one individual: what we have is records of imperfect male organs and imperfect

TABLE 1. Selected morphological characters distinguishing *Dioscorea lisae* and *D. coriacea*.

	D. lisae	D. coriacea
stems	terete	angular
leaves	5–7 nerved	7–9-nerved
pedicel length	5–8 mm	2–4 mm
capsule size	2–3 × 1.2–1.4 cm	1–2 × 0.5–0.8(–1.2) cm
capsule apex	rounded	acute

female organs intruded into what may be fertile individuals of the other sex." Al-Shehbaz and Schubert (1989: 67) referred to the reports of such deviation as "abnormally-monoecious"; Huber (1998: 220) cited a "a few reports of monoecy, most of them referring to American species ..."; and Caddick et al. (2002: 109) wrote that plants of *Dioscorea* are "dioecious but vestigial male/female parts [are] usually present." Xifreda (1982a, b; 1983; 1984), studying Argentinian species of *Dioscorea*, described *D. furcata* Griseb., *D. hieronymi* Uline ex R. Knuth, *D. megalantha* Griseb., *D. stenopetala* Hauman (all sect. *Cycladenium*), *D. demourae* Uline ex R. Knuth, *D. haumanii* Xifreda (both sect. *Monadelpha* Uline), and *D. pilcomayensis* Haumen (sect. *Centrostemon* Griseb.) as monoecious. She also observed infraspecific variation in male flowers of several species, notably *D. megalantha*; in some collections the glandular disc is not readily apparent or is incompletely developed, while in others it is fully accrescent. She attributed this anomaly to collections being made at different stages in floral development. Hammel (2000), relying upon his field knowledge of populations of *D. lepida* C.V. Morton (sect. *Trigonobasis*), recently reported that this Central American species is monoecious and that it flowers precociously with staminate flowers, then produces pistillate flowers toward the apex of an inflorescence and even some hermaphroditic flowers. Plants of *D. lepida* observed in a later flowering or fruiting stage consequently show little or no evidence of the staminate inflorescences. Given the evidence presented here and by Hammel (2000), it seems clear that careful field observations need to be coupled with herbarium, laboratory, and greenhouse studies to clarify what could be a wide range of different floral sex strategies in *Dioscorea*.

ACKNOWLEDGMENTS

Field work was supported by funds from the Biological Survey and Inventories Program of the National Museum of Natural History, and herbarium work by the Andrew W. Mellon Foundation. We are indebted to the staff of Guaramacal National Park for generous assistance in the field; the Ministerio del Ambiente and INPARQUES for collecting permits; the curators of MO, NY, and VEN for the use of their collections; the staff of the Missouri Botanical Garden Library for photocopies of the field books of J.A. Steyermark; and Barry Hammel (MO),

Lauren Raz (NY), and an anonymous reviewer for critical comments. The illustrations were prepared by Alice Tangerini.

BOOKS FROM TIMBER PRESS

JUDY GLATTSTEIN. 2003. **Consider the Leaf: Foliage in Garden Design.** (ISBN 0-88192-571-3, hbk.). Timber Press, Inc., 133 S.W. Second Avenue, Suite 450, Portland, OR 97204-3527, U.S.A. (Orders: www.timberpress.com, 800-327-5680, 503-227-2878, 503-227-3070 fax). $22.95, 307 pp., 114 color photos, 4 line drawings, 6" × 9".

This book is all about the primary photosynthetic organ of most plants, the leaf. The author considers "foliage the fundamental component of garden design, with flowers an added bonus." Contents: **1)** Designing with Foliage; **2)** Considerations of Color; **3)** Into the Shade; **4)** Golden Treasures; **5)** Dusky Delights; **6)** Shimmering Selections; **7)** Varied Variegation; **8)** Herbs and Edible Ornamentals; **9)** Geometry in the Garden; **10)** The Seasonal Garden; followed by a Metric Conversion Chart, Bibliography and Plant Name Index.

MASHA BENNETT. 2003. **Pulmonarias and the Borage Family.** (ISBN 0-88192-571-3, hbk.). Timber Press, Inc., 133 S.W. Second Avenue, Suite 450, Portland, OR 97204-3527, U.S.A. (Orders: www.timberpress.com, 800-327-5680, 503-227-2878, 503-227-3070 fax). $39.95, 240 pp., 101 color photos, 35 line drawings, 6 maps, 7 3/8" × 9 3/4".

From the back dust jacket: "This fully illustrated full-colour book is the first work on the family Boraginaceae that details biology, ecology and cultivation of over 200 species and hundreds of varieties. This book is an indispensable guide for gardeners, horticulturists and botanists who want to grow pulmonarias and other flowers in the borage family, or study them in the wild."

Key Words: Pulmonaria, Boraginaceae, cultivation, propagation, biology, classification. Wow, I didn't realize there were so many members of the Borage family that made outstanding garden plants.—*Barney Lipscomb, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX 76102-4060, U.S.A., barney@brit.org.*

GRAHAM NICHOLLS, RICK LUPP (Consulting Editor), foreword by BOBBY WARD. 2003. **Alpine Plants of North America: An Encyclopedia of Mountain Flowers from the Rockies to Alaska.** (ISBN 0-88192-548-9, hbk.). Timber Press, Inc., 133 S.W. Second Avenue, Suite 450, Portland, OR 97204-3527, U.S.A. (Orders: www.timberpress.com, 800-327-5680, 503-227-2878, 503-227-3070 fax). $49.95, 344 pp., 495 color photos, 2 maps, 7 3/8" × 10 3/8".

From the inside front dust jacket flap: "*Alpine Plants of North America* is a comprehensive pictorial look at the American mountain flora from the southernmost Rocky Mountains to the Brooks Range of Alaska. *Alpine Plants of North America* provides a wealth of information for the alpine enthusiast at home and in the field. Approximately 650 species in 54 genera are discussed, with many subspecies, varieties, and hybrids also described." What an information bank on alpine plants of North America this book is!

Key Words: Alpine plants; mountain plants (West U.S., Canada, western); wild flowers; identification, cultivation.

FESTUCA DENTIFLORA (POACEAE: LOLIINAE: SECT. *GLABRICARPAE*), A NEW SPECIES FROM PERU AND TAXONOMIC STATUS OF *F. PRESLIANA*

ABSTRACT

A new species, *Festuca dentiflora* E.B. Alexeev ex Stančík & P.M. Peterson from the Andes of Peru, is described and illustrated. The new species is a member of *Festuca* subg. *Subulatae* (Tzvelev) E.B. Alexeev sect. *Glabricarpae* E.B. Alexeev and is apparently closely related to *Festuca caldasii* (Kunth) Kunth from Ecuador and Colombia. A key to the species of *Festuca* sect. *Glabricarpae* is included. In addition, the taxonomic status and geographical origin of *F. presliana* is discussed.

RESUMEN

Se describe e ilustra una especie nueva de *Festuca* de los Andes de Perú: *F. dentiflora* E.B. Alexeev ex Stančík & P.M. Peterson. La nueva especie pertenece a *Festuca* subg. *Subulatae* (Tzvelev) E.B. Alexeev sect. *Glabricarpae* E.B. Alexeev, se considera estrechamente relacionada aparentemente con la especie *F. caldasii* (Kunth) Kunth de Ecuador y Colombia. Se presenta también una clave para la determinación de las especies de *Festuca* sect. *Glabricarpae*. Además, se discute el estatus taxonómico y origen geográfico de *F. presliana*.

The Russian botanist, E.B. Alexeev, recognized several specimens with unique features while studying South American material of *Festuca* in the United States National Herbarium (US). Alexeev marked many specimens as new species with herbarium names, however, some of these were never published. The status of some of his proposed new species is problematic since, in many cases, only type material exists, and species concepts in *Festuca* are highly variable. In this paper, we describe a new grass species from Peru based upon a specimen that was selected and given an herbarium name by E.B. Alexeev.

The new species, *Festuca dentiflora* E.B. Alexeev ex Stančík & P.M. Peterson, appears to belong in *Festuca* subg. *Subulatae* (Tzvelev) E.B. Alexeev, sect. *Glabricarpae* E.B. Alexeev, in the subtribe Loliinae, tribe Poeae, and subfamily Pooideae (Soreng et al. 2000). Section *Glabricarpae* is one of four sections (sect. *Elmera* E.B. Alexeev, sect. *Glabricarpae*, sect. *Longiglumes* S.L. Lu, and sect. *Subulatae* E.B. Alexeev) in subg. *Subulatae* (Tzvelev) E.B. Alexeev. Section *Glabricarpae* differs from sect. *Elmera* by having flat leaf blades without prominent ribs, and differs from most species of sect. *Subulatae* by having ovate spike-

lets that are significantly longer (> 11 mm long), scabrous lemmas (usually glabrous in sect. *Subulatae*), significantly longer anthers (3.5–5 mm long), and glabrous ovary apices. While the distribution of species in sect. *Elmera* is restricted to the southwestern North America, sect. *Longiglumes* is known only from China and sect. *Subulateae* is sub-cosmopolitan in its distribution (Lu 1992; Stančík & Peterson 2002). By inclusion of the new species, sect. *Glabriformae* consists of five species, two (*F. breviglumis* Swallen, *F. chiriquensis* Swallen) restricted to Mesoamerica and three (*F. caldasii*, *F. dentiflora*, *F. woodii* Stančík) found in northern South America (Alexeev 1980, 1982, 1986; Stančík 2001, 2003). Based on morphological comparisons, *F. dentiflora* appears closely related to *F. caldasii* (Kunth) Kunth.

Festuca dentiflora E.B. Alexeev ex Stančík & P.M. Peterson, sp. nov. (**Fig. 1**). TYPE: PERU. DEPARTAMENTO HUÁNUCO. Provincia Baños: U.S. Exploring Expedition of Capt. *Wilkes* 5 (HOLOTYPE: US-1006459!).

Haec species a *Festuca caldasii* (Kunth) Kunth spiculis 11–12 (non 15–17) mm long., glumis majoribus (inferioribus 4.5–6 non 3.5–4 mm long., superioribus 7–8 non 4.5–6.5 mm long.), lemmate minoribus (8.5–10 non 10–14 mm long.), aristis majoribus (6–8 non 1–3 mm long.) differt.

Perennial, loosely tufted. Culms about 100 cm tall, erect, glabrous, with 2–4 nodes in basal half. Sheaths membranous, glabrous, margins free, innovations extravaginal; auricles absent. Ligules 3.5–4 mm long, membranous, acute, lacerate. Blades (only a fragment seen) 3–4 mm wide, flat, green, glabrous. Panicles about 20 cm long, 10–15 cm wide, ovate; branches erect or sometimes spreading, in pairs at each node, scabrous. Spikelets 11–12 mm long, ovate; florets 4–5 (perfect); rachillas 1.2–1.8 mm long, densely pilose. Glumes lanceolate, brownish-green with membranous margins; lower glume 4.5–6 mm long, 1-veined; upper glume 7–8 mm long, 3-veined. Lowermost lemmas 8.5–10 mm long, lanceolate, coriaceous-membranous, green, hairy, 5-veined; apex bi-dentate with an awn 6–8 mm long; callus glabrous. Paleas almost as long as lemma, membranous, two-keeled, scabrous; apex two-dentate, hairy. Lodicules oblong-lanceolate. Stamens 3; anthers 4.5–5 mm long. Ovary apex glabrous. Caryopses not observed.

Transversal section of leaf blade.—Leaf section with many vascular bundles, without ribs; bulliform cells not observed; sclerenchyma under both abaxial and adaxial epidermis discontinuous, without hairs.

Distribution.—Known only from the type locality in Peru.

Etymology.—The specific epithet, as marked on the specimen by E.B. Alexeev, probably refers to the bi-dentate lemma and palea.

DISCUSSION

Section *Glabricarpae* is quite homogenous and all five species (*F. breviglumis*, *F. caldasii*, *F. chiriquensis*, *F. dentiflora*, *F. woodii*) are morphologically very simi-

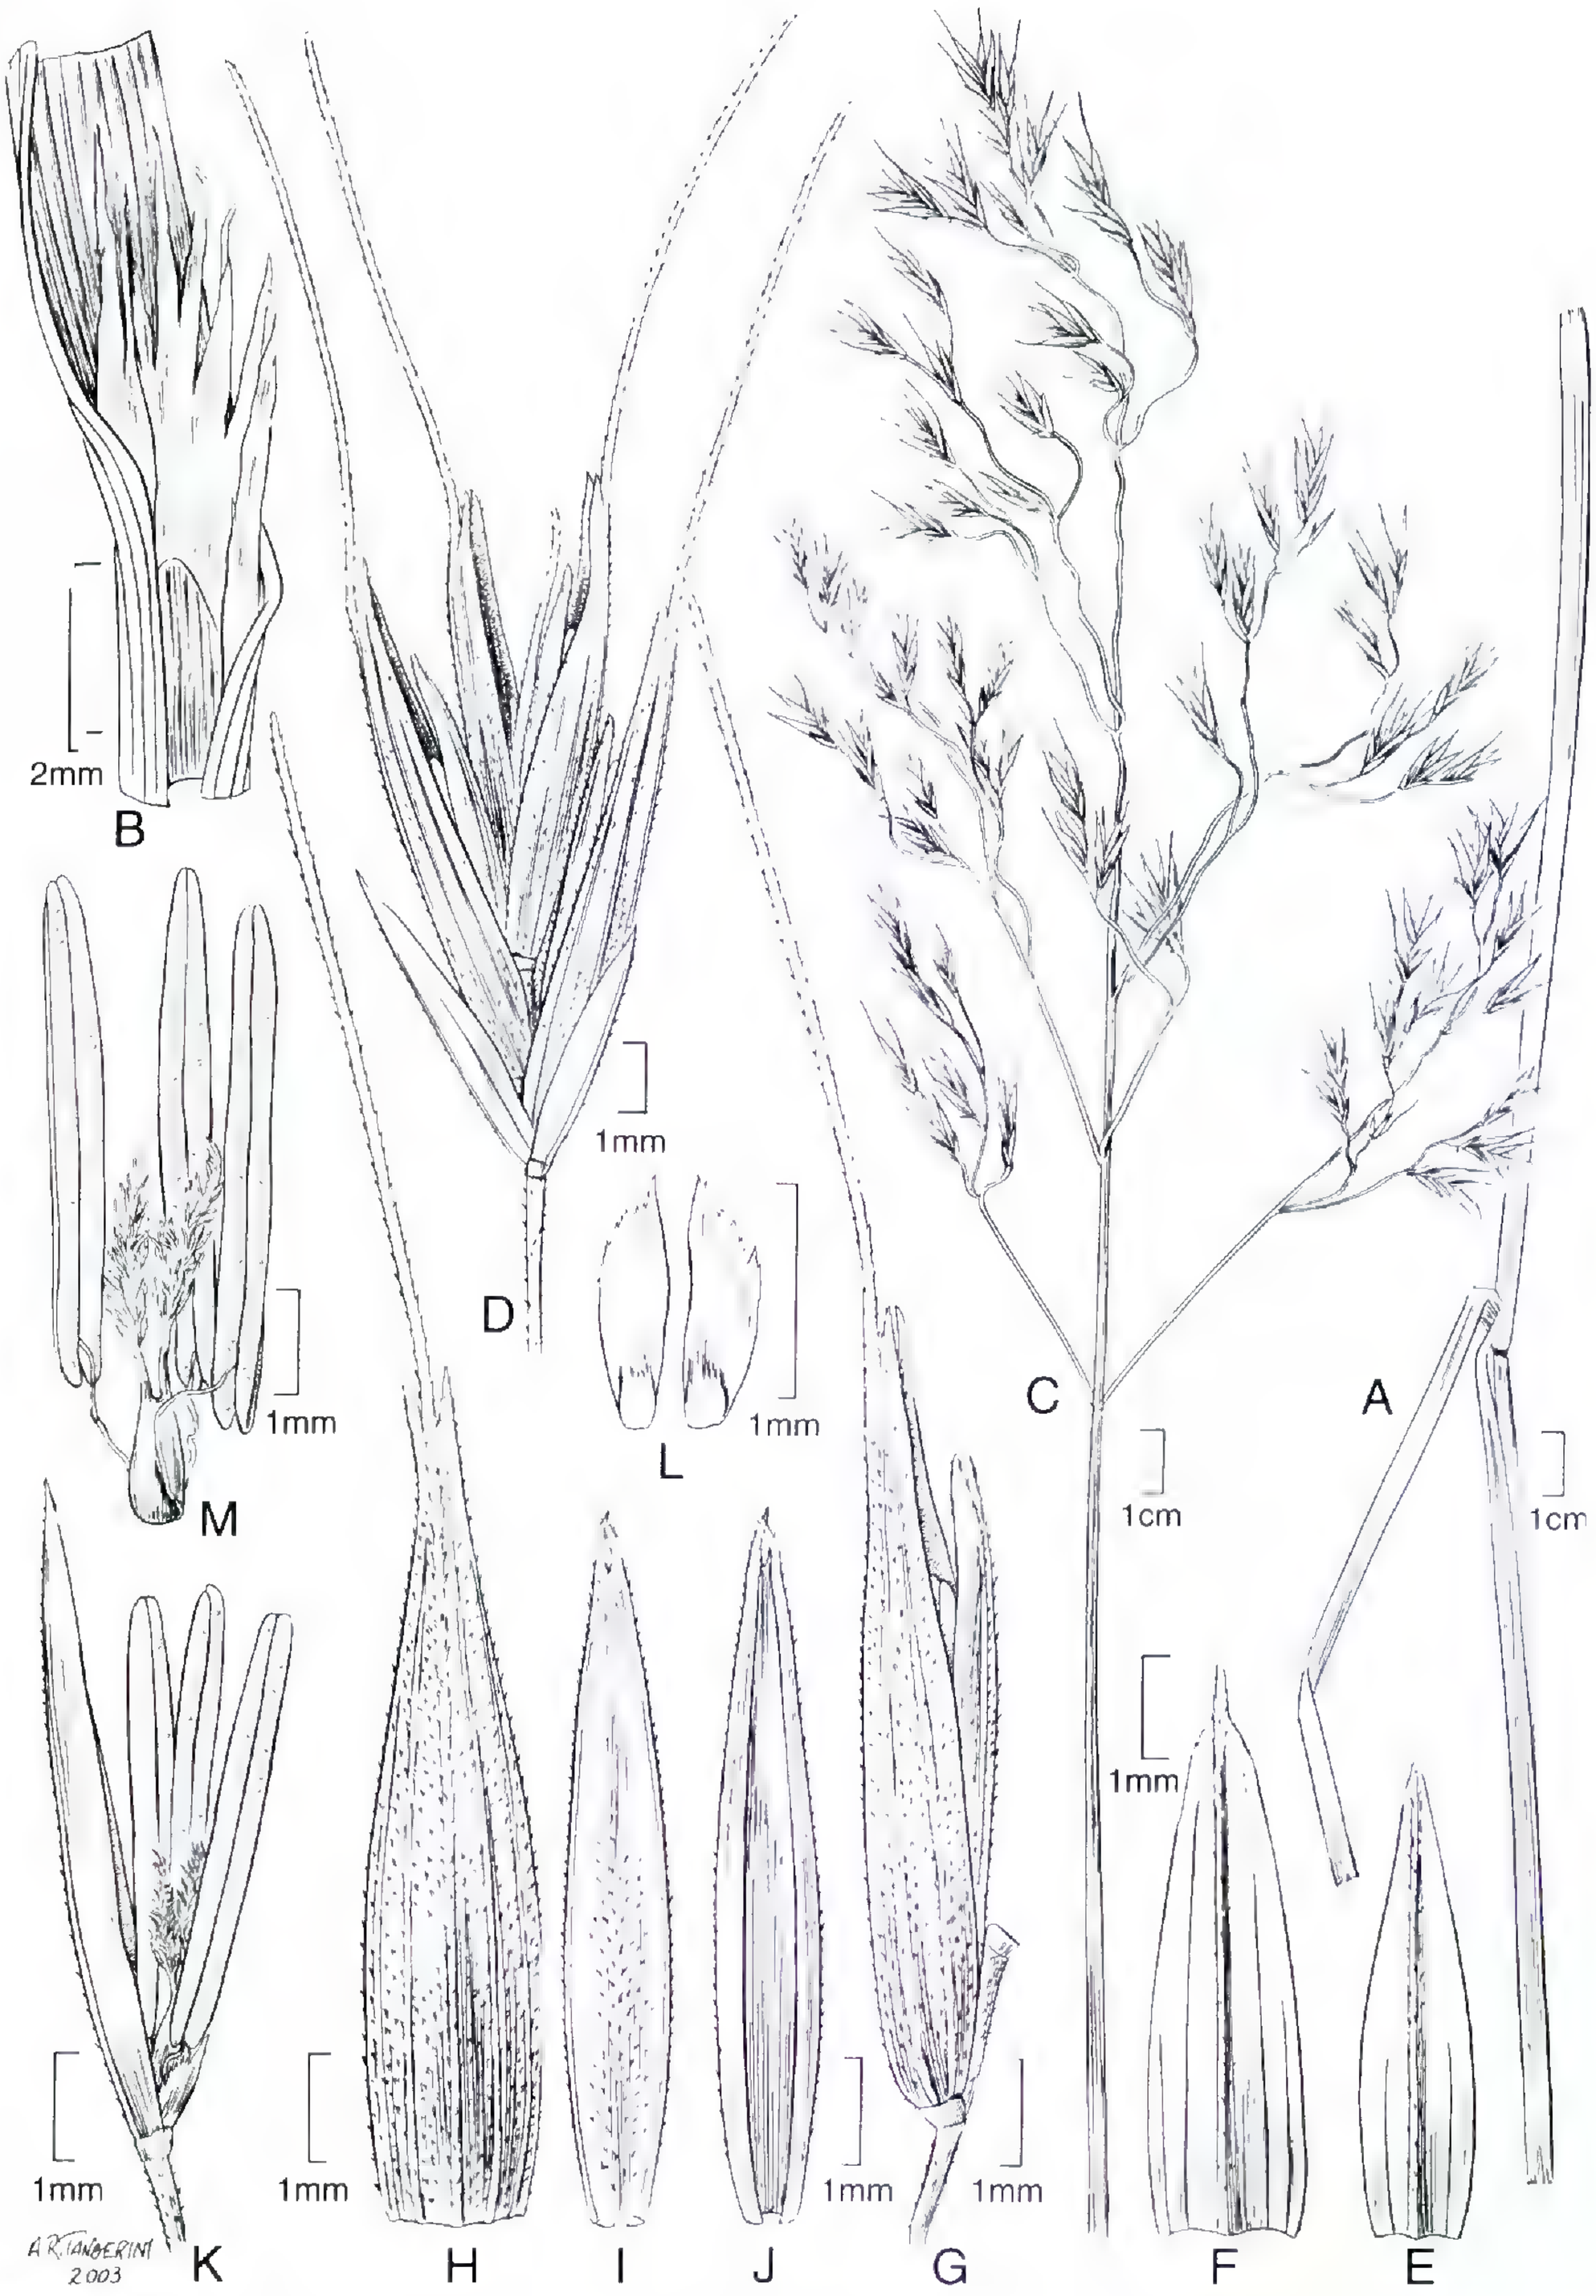

FIG. 1. *Festuca dentiflora* (*Wilkes 5*). A. Culm (portion of). B. Sheath, ligule, and portion of the blade. C. Inflorescence. D. Spikelet. E. Floret. F. Lower glume, dorsal view. G. Upper glume, dorsal view. H. Lemma, dorsal view. I. Palea, dorsal view. J. Palea, ventral view. K. Palea, lodicules, stamens, and pistil. L. Lodicules (2). M. Stamens and pistil.

lar (Table 1). In comparison with other members of this section, *F. dentiflora* and *F. woodii* have shorter spikelets (11–14 mm long verses 15–20 mm long), *F. dentiflora* and *F. caldasii* have longer ligules (2.5–4 mm long verses 0.5–1.1 mm long), and *F. dentiflora* and *F. breviglumis* have longer awns (6.5–15 mm long verses 0.5–4 mm long).

KEY TO THE SPECIES OF *FESTUCA* SECT. *GLABRICARPAE* IN SOUTH AMERICA

1. Spikelets 10–14 mm long, lemmas 10–16 mm long.
   2. Lower glumes 7–8.5 mm long, upper glumes 9–12 mm long _____ **Festuca chiriquensis**
   2. Lower glumes 3.5–5(-6.5) mm long, upper glumes 4.5–8.5 mm long.
      3. Ligules 0.5–0.8 mm long, lemma awn 7–15 mm long _____ **Festuca breviglumis**
      3. Ligules 0.5–3 mm long, lemma awn 1–3 mm long _____ **Festuca caldasii**
1. Spikelets 15–20 mm long, lemmas 8.5–9.5 mm long.
   4. Ligules 0.5 mm long, lemma awn 0.5–1 mm long, anthers 3.5–3.7 mm long _____ **Festuca woodii**
   4. Ligules 3.5–4.5 mm long, lemma awn 0.5–1 mm long, anthers 3.5 3.7 mm long _____ **Festuca dentiflora**

Alexeev (1986) also included *F. presliana* Hitchc. in sect. *Glabricarpae*, but the status of this species is not clear (see Table 1). The type specimen of *F. presliana* differs from the other members of sect. *Glabricarpae* by having 3-veined, membranous, and papillate or short scabrous (not long scabrous) lemmas. Since *F. presliana* has lanceolate lemmas with long awns and short anthers it may be more correctly placed in *Festuca* subg. *Subulatae* sect. *Subulatae*. The type specimen of *F. presliana* was originally described as *Bromus depauperatus* J. Presl [Reliq. Haenk. 1(4-5): 263.1830] from a specimen (*Haenke s.n.*) collected by the Czech botanist, Thaddaeus Peregrinus Xaverius Haenke, as a member of Malaspina Expedition (1789-1793). Haenke collected about 15,000 plant specimens on this expedition. However, a large part of this material was destroyed during transportation (Stern 1973) and only a small part of the collection reached the European continent and was finally acquired by Kaspar von Sternberg in 1821 for the National Museum in Prague. Under the leadership of K.B. Presl, processing and determination of this material and results were published in Reliquiae Haenkeanae (Presl 1825-30, 1831-35). New grass species were described by J.S. Presl. A major part of this collection has recently been deposited in the National Museum Herbarium in Prague (PR), and duplicate sets can be found in the Herbarium of Charles University in Prague (PRC) and in other herbaria (K, MO, US, W).

A taxonomic revision of *Festuca* in Colombia has recently been completed by the senior author (Stančík 2003), and the status of *F. presliana* is still unclear. While Presl described the type specimen as *Bromus depauperatus* and mentioned "sinu Nootka" (=Vancouver Island) as the type locality, Hitchcock (1927) in his treatment of South American grasses, transferred this taxon to the genus *Festuca* and created a new name *F. presliana* Hitchcock to replacing the

blocking name, *F. depauperata* Bertol (Fl. Ital.1: 620.1834). Hitchcock also discussed the geographical origin of this specimen comparing Haenke´s collection with the specimen of Wilkes Expedition (type specimen described here as *F. dentiflora*). Hitchcock concluded that the type locality published by Presl was in error because neither the specimens nor the description corresponds with any North-American species of *Festuca*. Hitchcock, suspected the "true identity" of the *F. presliana* type to be from Baños, Peru. This opinion, at first, appeared highly probable because a large portion Haenke´s specimens come from Huánuco region of central Peru (Fig. 1b in Kühnel 1960). In the Flora of Peru, Macbride (1936) also accepted Hitchcock's opinion.

Alexeev (1986) opened a new discussion on the geographical origin Haenke's specimen and compared the northern South American collections of *Festuca* with a specimen of Killip [*Killip & Smith 19719* (US)] from the Cordillera Oriental of Colombia. Alexeev concluded that Hitchcock´s opinion of the Peruvian origin was erroneous and that *Festuca presliana* is a species endemic to Colombia.

There are no doubts about the placement of Haenke's specimen in the genus *Festuca* since it has an open sheath, glabrous ovary, and a caryopsis that does not adhere to the lemma. A comparison of the type specimens of *Haenke s.n.*(*F. presliana*) and *Wilkes 5* (*F. dentiflora*) with the Killip & Smith specimen, suggests that Peruvian and Colombian origin of *F. presliana* are in error. The specimens do not represent the same species (see Table 1 for comparison). The Peruvian specimen (*Wilkes 5*) is described here as a new species (*F. dentiflora*), and the Killip & Smith specimen represents a new species (*F. venezuelana*) from Venezuela (Stančík 2003). In addition to the specimen comparisons above, a reconstruction of Haenke´s itinerary in South America indicates (Fig. 1a & b in Kühnel 1960) that he never reached the Cordillera Oriental of Colombia. A reexamination of Haenke´s specimen using Hitchcock and Chase (1951), Soderstrom and Beaman (1968), Stewart and Hebda (2000), Serna and López-Ferrari (2000), Beetle (1991), Macbride (1936), Pinto-Escobar (1981), and Davidse (1994) also excluded the possibility that it is of American origin.

The most important morphological feature distinguishing *F. presliana* is the 3-veined lemma, that is commonly 5–15-veined in *Bromus* and usually 5-veined in *Festuca*. Interestingly, there are only five known species of *Festuca* with 3-veined lemmas. In addition to *F. presliana*, Clayton and Renvoize (1986) mentioned the following four species with 3-veined lemmas: *F. africana* (Hack.) Clayton and *F. engleri* Pilg. From Africa, *F. altissima* Boiss. from Eurasia, and *F. asthenica* Hook. f. from Asia. All of these species come from the Old World. The two African species are placed in the wide-spread, *Festuca* Subg. *Subulatae* (Stančík in prep.), whereas the Eurasian/Asian species are alligned with *Festuca* Subg. *Drymanthele* (Aleexev 1977). The occurrence of taxa with 3-veined lem-

mas in the Old World is remarkable. However, use of this observation as support for the extra-American origin of this Haenke type is probably insufficient. Other cases of confusion in the location of Haenke´s collections are known, for example, Alston (1934), Lamson-Scribner (1899), Merrill (1906), and Veldkamp et al. (1991). Frequently there is confusion with reports of South American species as occurring in Luzon (Philippines) and vice versa. Revision of *Bromus* and *Festuca* in the Philippines is needed and could clear up some of this confusion.

ACKNOWLEDGMENTS

We wish to thank the Smithsonian Institutions, Fellowships and Grants for supporting a research visit by the senior author to the United States National Herbarium and curators from the following herbaria: AAU, B, COL, LPB, MA, PR, PRC, QCA, QCNA, VEN, and W. Financial aide to visit herbarium collections was made possible by support from GAČR (No.206/01/0687) and a grant from the Ministry of Education of Czech Republic (No.313004). Appreciation is extended to Alice R. Tangerini for providing the illustrations; Dan Nicolson for correcting the Latin diagnoses; and to Kelly W. Allred, Barney Lipscomb, and Stephan L. Hatch for reviewing the manuscript.

THE GENUS *PACKERA* (ASTERACEAE: SENECIONEAE) IN COLORADO, U.S.A.

Debra K. Trock[1]

Botanical Research Institute of Texas
509 Pecan Street
Fort Worth, TX 76102-4060, U.S.A

ABSTRACT

Fourteen species of *Packera* are known to occur in Colorado. Recently published floras for the state have treated these species variously as *Packera*, *Senecio* and *Ligularia*. While preparing a treatment of this genus for the Flora of North America Project, the author discovered some confusion among the local botanists who rely on those floras for identifications of this difficult group. This paper presents descriptions for each of the species that occur in the state, comments on how to differentiate them in the field, and identification keys.

RESUMEN

Se conocen catorce especies de *Packera* en Colorado. Las floras del estado publicadas recientemente han tratado estas especies de modo diferente como *Packera*, *Senecio* y *Ligularia*. Mientras preparaba un tratamiento de este género para la Flora de Norte América, el autor encontró confusión entre los botánicos locales que usan estas floras para las identificaciones de este grupo difícil. Este artículo presenta descripciones de las especies que viven en el estado, comentarios sobre como diferenciarlas en el campo, y claves de identificación.

INTRODUCTION

What Distinguishes a *Packera* from a *Senecio*?

Traditionally, species now included in *Packera* were relegated to the genus *Senecio*, a large genus of over 3,000 species. In the early 1800s DeCandolle (1838) provided a worldwide treatment of *Senecio*. He recognized 16 informal groups, based largely on geographic distribution. Greenman (1915, 1916, 1917, 1918) and Rydberg (1900) had varying definitions and numbers of informal "species groups." Through the 1960s into the 1980s Barkley (1962, 1968a, 1968b, 1978, 1980) published several papers on three of these informal groups, the *Aurei*, the *Lobati* and the *Tomentosi*, which he collectively referred to as the "Aureoid Senecios."

Within *Senecio* s.l., most of the taxa have a base chromosome number of x=10 or derivatives thereof. However, Löve and Löve (1976) pointed out that there was a group of anomalous species whose chromosomal base number was either x=22 or x=23 and had a suite of unique morphological characters. Furthermore those taxa corresponded to three New World groups informally recognized by Barkley: the *Aurei*, the *Lobati*, and the *Tomentosi*. They proposed that these species be placed in a new genus, *Packera*, based primarily on gross morphology and chromosome number.

[1]Current address: Michigan State University, 166 Plant Bio ogy, East Lansing, MI 48824-1312, U.S.A.

The recognition of *Packera* was not immediately accepted and still is not recognized by some workers. However, support for recognizing *Packera* has grown over the past 25 years. Molecular, palynological, and cytological data, while doing little to help clarify relationships between species in this group, have all lent support for recognizing the genus *Packera*. These types of data are acquired by laboratory work, but how does a botanist in the field decide if he/she is looking at a *Packera* or a *Senecio*? Table 1 provides a comparison of characters that are useful for field or herbarium identifications. Often a combination of these features will be needed to make a determination.

MATERIALS AND METHODS

While preparing a treatment of the genus *Packera* for the *Flora of North America* project, I borrowed specimens from many regional herbaria, and visited several others to obtain both accurate distribution records, and a good understanding of the morphological variation that is characteristic of these species. I have also made four collecting trips through the central part of Colorado, where the diversity of *Packera* is the highest. During the course of that work it became apparent that there was confusion among local botanists concerning which characters provide for accurate identification, and about which species belong in the genus *Packera*, and which are still treated as *Senecio* s.l.

I have examined over 1100 Colorado specimens from the following herbaria: Adams State College (ALAM); Botanical Research Institute of Texas (BRIT); Brigham Young University (BRY); Canadian Museum of Nature (CAN); Colorado College (COCO); Colorado State University (CS); Kansas State University (KSC): Miami University (MU); Missouri Botanical Garden (MO); Montana State University (MONT); New York Botanical Garden (NY); North Dakota State University (NDA); Northeast Louisiana University (NLU); Oregon State University (OSC); Rancho Santa Ana Botanic Garden (RSA); Rocky Mountain Herbarium (RM); University of Alaska Museum (ALA); University of British Columbia (UBC); University of California (UC); University of Colorado (COLO); University of Kansas (KANU); University of New Mexico (UNM); University of Southern Colorado (PUSC); University of Washington (WTU); and Vanderbilt University (VDB).

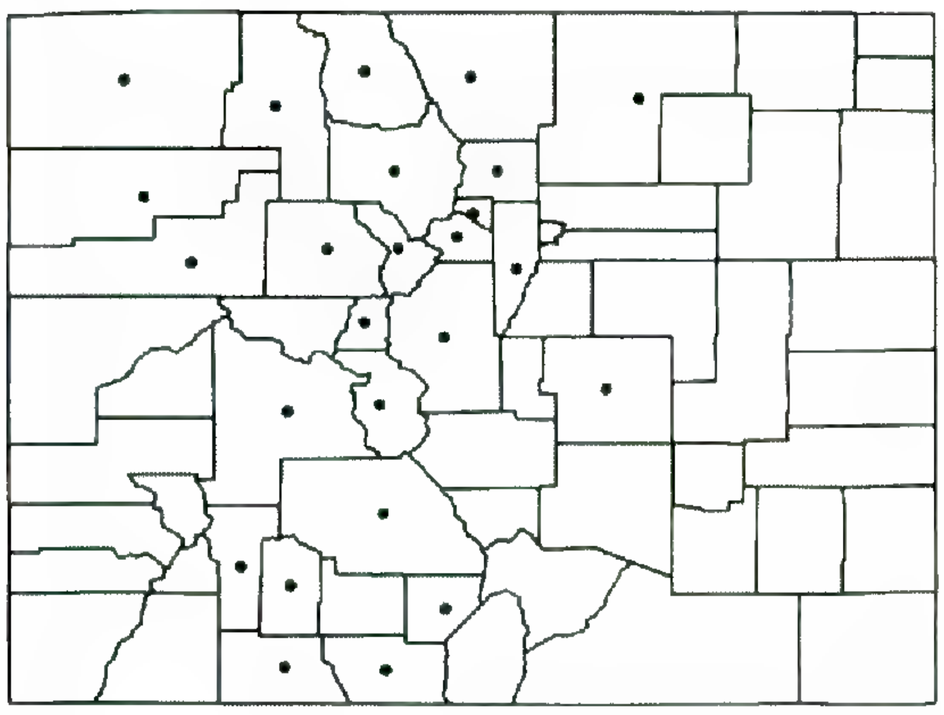
The goal of this paper is to provide descriptions, keys, common synonyms, and a discussion of the most useful morphological characters to assist botanists in their efforts to accurately identify species in this genus. Dot maps providing distribution information for each species are presented in Figures 1, 2 and 3.

Generic characters of Colorado *Packera* species

All taxa of *Packera* are exclusively herbaceous, and most are perennials. Three of the Colorado species, *P. multilobata*, *P. plattensis*, and *P. neomexicana* can also

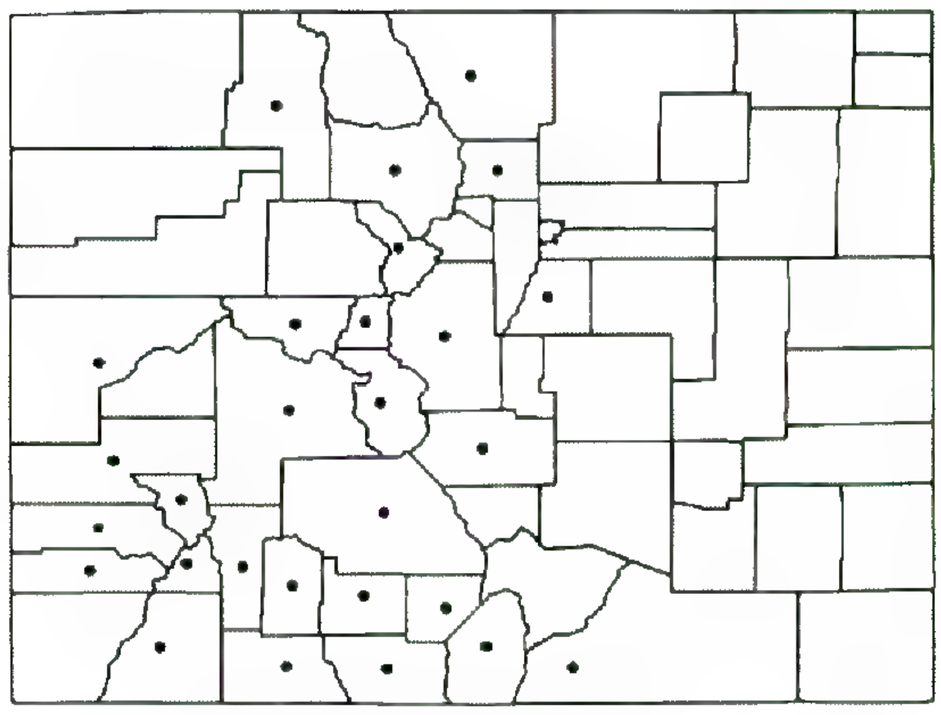
TABLE 1. Comparison of characters useful for field or herbarium identifications of *Packera* and *Senecio*.

Packera	Senecio	Informal Groups of Barkley within *Senecio*
Leaves progressively reduced distally	Leaves concentrated distally, or equally distributed along the stem	*Suffruticosi*
Heads erect on peduncles	Heads nodding	*Amplectentes*
Phyllaries occasionally with reddish tips. Rarely black-tipped, and if so, middle cauline leaves NOT clasping	Phyllaries with prominent black tips, AND middle cauline leaves clasping	*Amplectentes*
Caudices taprooted or rhizomatous, with branching fibrous lateral roots	Caudices button-like or lateral rhizomes, with fibrous roots unbranched and fleshy	*Lugentes, Boreali, Integerrimi*



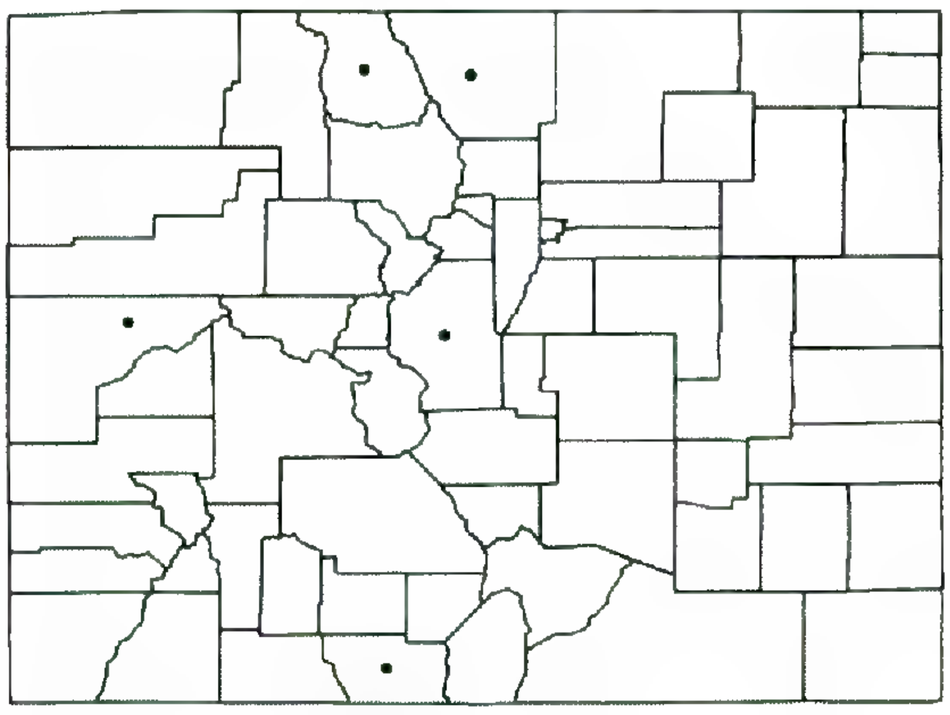
be biennials, and *P. neomexicana* may occasionally be a winter annual. Stems of all Packeras consistently grow from either a single or a cluster of basal rosettes.

The perennating structure is a woody caudex or a shortened rhizome. A caudex is the persistent base of an herbaceous stem that normally arises from a taproot. In some species the caudex is short, thin, and weak, while in others it can become elongated, branching, stout, and woody. Species that inhabit steep rocky slopes have creeping rhizomatous caudices. Taxa growing in wet meadows or other mesic environments frequently have abundant fibrous roots, which may almost completely disguise the presence of the caudex.

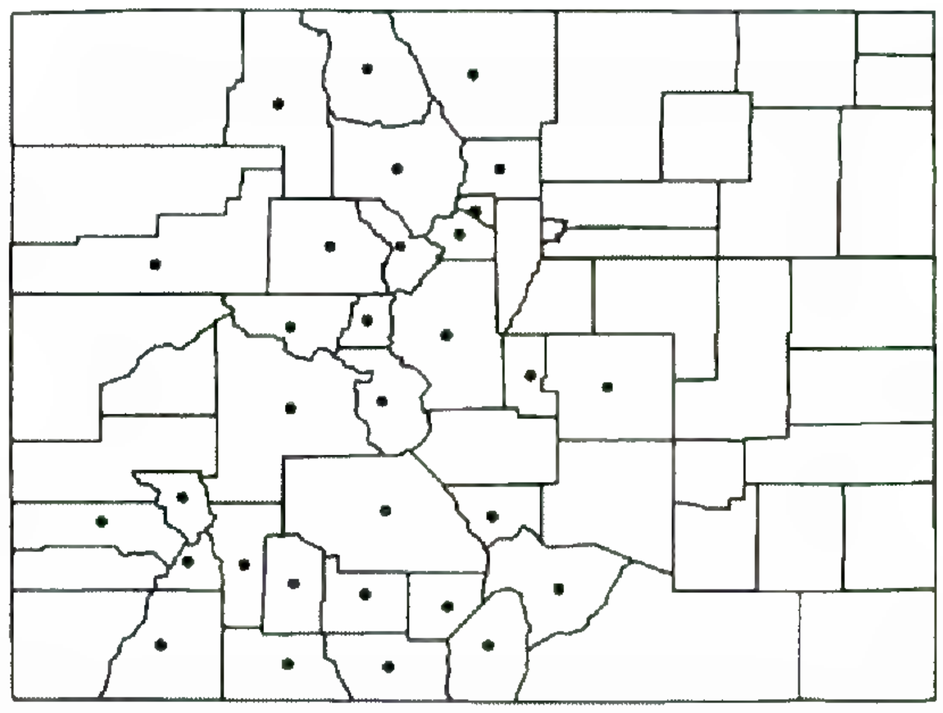


Stems are normally single from the caudex or taproot. However, because in many species the caudex is more or less branching, it may appear that there are several stems clustered together, but usually no more than four or five. Some species may have stems that display anthocyanic (reddish) pigments. *P. multilobata*, growing in open sagebrush habitats, and *P. porteri*, growing on talus slopes both exhibit this characteristic.

There is considerable variation in the amount of pubescence along the stems. In Colorado, *P. cana, P. fendleri*, and *P. werneriifolia* are nearly always densely tomentose. Other species vary widely in the amount and persistence of tomentum. Almost all Packeras have at least some pubescence restricted to the base of the stem and to the axils of the leaves when young. Although the presence or absence and location of pubescence is commonly used in keys and descriptions, it should only be used in conjunction with other characters when identifying specimens.



The shape and texture of basal leaves have long been of key taxonomic importance in the genus. The shape of the blade, base of the blade, and blade margins are the three most important characters. In general the basal leaves are



Packera cana

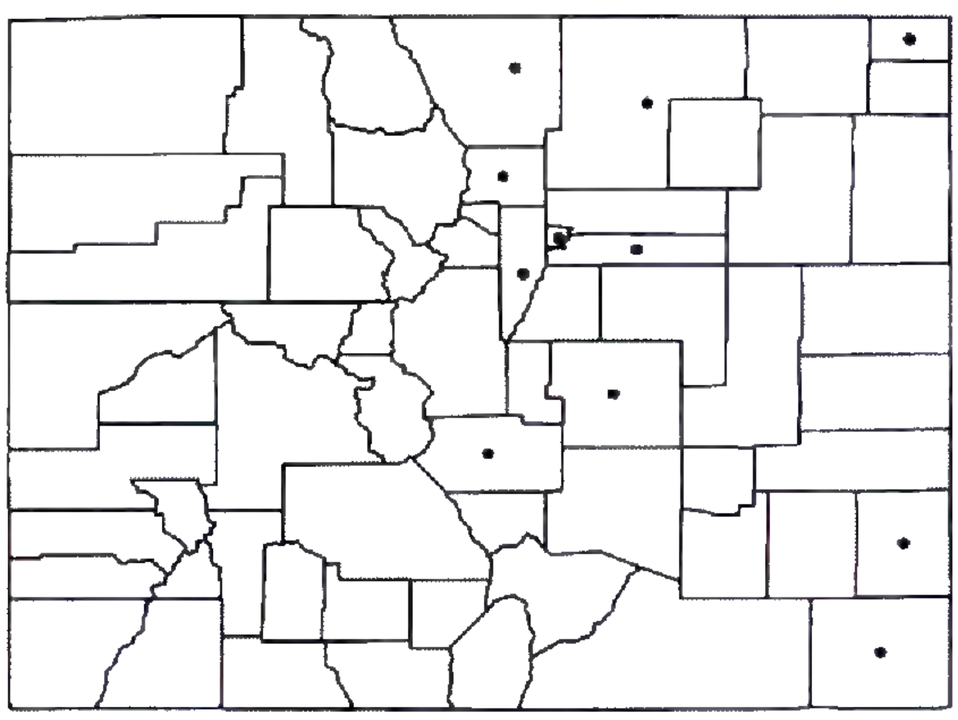
petiolate. The only exception among Colorado Packeras is *P. werneriifolia*. Some individuals of this species have basal leaves that are sessile.



The shape and size of cauline leaves can also be useful, but there may be extreme variability within species. In all species of *Packera*, the basal leaves are arranged in rosettes, while the cauline leaves are either gradually, progres-

sively, or abruptly reduced upwards on the stem. In all species, the uppermost cauline leaves are sessile and most are bract-like.

The heads in the inflorescence are arranged in either subumbellate or corymbiform cymes. Two species (*P. porteri* and *P. werneriifolia*) nearly always have only one large terminal head or at most two or three smaller heads.

Most species of *Packera* have 8 or 10 or 13 ray florets per head. However, *P.*

Packera tridenticulata

Packera werneriifolia

Fig. 3. Distribution maps for *Packera* species in Colorado (continued).

debilis, is typically rayless. A few others, including *P. paupercula*, *P. porteri*, *P. pseudaurea*, and *P. werneriifolia* are occasionally rayless. In most species the florets are a bright yellow. *P. dimorphophylla var. dimorphophylla* and *P. crocata* frequently have florets that are deep orange-yellow to almost brick-red. *P. streptanthifolia* may have rays that are a deep orange-yellow as well.

Another character that is frequently used in descriptions is size and pubescence of the cypselae. While there is variation in size, *P. cana* has noticeably large fruits and *P. dimorphophylla* has noticeably small ones. Many species have glabrous fruits, but a few have tiny hairs along the ribs of the cypselae.

KEY TO THE PACKERAS OF COLORADO

1. Plants distinctly tomentose throughout, or occasionally glabrate.
   2. Margins of leaf blades shallowly but evenly pinnatifid to pinnatisect or merely wavy _____ **P. fendleri**
   2. Margins of leaf blades variously entire or dentate, but not pinnatifid.
      3. Plants with 1–3(–5) large heads, alpine to sub-alpine, scapose or with cauline leaves reduced to mere bracts _____ **P. werneriifolia**
      3. Plants without the above combination of characters.
         4. Plants persistently lanate or canescent, leaf blades ovate or elliptic, or rarely broadly lanceolate, leaf margins entire or merely wavy _____ **P. cana**
         4. Plants with persistent dense tomentum at least at the base of the stem and in leaf axils. Lightly tomentose elsewnere, glabrescent with age.
            5. Basal leaves lanceolate, oblanceolate or narrowly elliptic, lower cauline leaves similar to basal leaves, calyculate bracts long and conspicuous. Plants of open meadows and coniferous woodlands at mid to high elevation _____ **P. neomexicana** var. **mutabilis**
            5. Basal leaves elliptic to ovate or oblanceolate, lower cauline leaves lyrate to pinnatisect, calyculate bracts few and inconspicuous. Plants of open prairies and grasslands _____ **P. plattensis**
1. Plants glabrous, may be tomentose when young, or persistently so in the axils of the leaves and at the base of the stem; or rarely lightly pubescent throughout.
   6. Heads rayless or ray florets much reduced, involucres greenish with anthocyanic

tips; lower and mid-cauline leaves pinnately lobed with deep rounded sinuses _____ **P. debilis**

6. Heads radiate, or if rays lacking only 1 head per stem and involucres deeply anthocyanic.
   7. Plants with a single large head; involucres deeply anthocyanic, basal leaves reniform to subreniform, cauline leaves reduced to bracts, plants of alpine scree slopes _____ **P. porteri**
   7. Plants with few to several heads, involucres and leaves without the above combination of characters.
      8. Basal leaf blades narrowly to broadly lanceolate, oblanceolate or narrowly elliptic.
         9. Lower cauline leaves similar to basal leaves, upper ones becoming sessile; calyculate bracts conspicuous and numerous but small; cypselae hirtel lous along the angles; plants of prairies and sagebrush habitats _____ **P. tridenticulata**
         9. Lower cauline leaves various; calyculate bracts either few and inconspicuous or large and conspicuous; cypselae glabrous; plants of mountain or wet meadow habitats.
            10. Involucres dark green, often with anthocyanic tips; heads with nu merous large conspicuous calyculate bracts _____ **P. streptanthifolia** var. **streptanthifolia**
            10. Involucres light green, tips not distinctly anthocyanic; calyculate bracts few and inconspicuous.
               11. Leaf blades broadly lanceolate to ovate; base of leaf blades truncate to subcordate or occasionally obtuse; lower cauline leaves sublyrate to subentire; middle and upper cauline leaves sessile and frequently clasping _____ **P. pseudaurea** var. **flavula**
               11. Leaf blades lanceolate to narrowly elliptic; base of leaf blades tapering to cuneate or obtuse, but never subcordate; lower cauline leaves often sublyrate or with margins variously dissected, but rarely subentire; middle and upper cauline leaves mere sessile bracts _____ **P. paupercula**
      8. Basal leaf blades broadly elliptic, obovate or oblanceolate to ovate or orbicular.
         12. Leaf margins lobed or pinnatifid; plants of sandy sagebrush habitats _____ **P. multilobata**
         12. Leaf margins variously dentate to crenate or shallowly lobed but never pinnatifid; plants of alpine to subalpine habitats.
            13. Lower and middle cauline leaves sessile, conspicuously clasping and auriculate _____ **P. dimorphophylla** var. **dimorphophylla**
            13. Lower and middle cauline leaves sessile or petiolate, may be weakly clasping but never auriculate.
               14. Leaf blades thin, margins entire to weakly crenate or merely wavy; upper cauline leaves sessile and weakly clasping; rays often deep orange yellow or brick red; calyculate bracts few or absent; plants of sub-alpine meadows _____ **P. crocata**
               14. Leaf blades thick and turgid, margins variously entire to conspicuously dentate; upper cauline leaves sessile and reduced to mere bracts; rays deep yellow, but never reddish; calyculate bracts conspicuous; habitats from damp to drying ____ **P. streptanthifolia** var. **streptanthifolia**

SPECIES DESCRIPTIONS AND COMMENTS ON IDENTIFICATION

Packera cana (Hook.) W.A. Weber & A. Löve, Phytologia. 49:46. 1981. *Senecio canus* Hook.

Senecio purshianus Nutt.; *Senecio canus* var. *purshianus* A. Nelson; *Senecio canus* var. *eradiatus* D.C.; *Senecio howellii* Greene; *Senecio hallii* Britton; *Senecio harbourii* Rydb.; *Senecio convallium* Greenm.; *Senecio oreopolus* Greenm.; *Senecio hallii* var. *discoidea* W.A. Weber

Perennials. **Caudices** stout, branching rhizomatous, suberect. **Stems** single from a rosette, or clustered rosettes, densely lanate-pubescent or canescent. **Basal leaves** petiolate, blades ovate or elliptic to lanceolate, 2.5–5+ × 1–3 cm, bases tapering, margins entire or irregularly undulate to weakly dentate, persistently canescent on lower surface, canescent to subglabrescent on upper surface. **Cauline leaves** petiolate to sessile and weakly clasping, progressively reduced distally, elliptic to lanceolate, margins entire to weakly dentate. **Heads** radiate, 8–15+ in corymbiform arrays. Peduncles bracteolate, densely lanate to floccose tomentose, subglabrescent in some populations. **Calyculi** present, inconspicuous, tomentose. **Phyllaries** 13 or 21, green, 5–8+ mm, densely tomentose. **Ray florets** 8–10 or 13, laminae 8–10+ mm. **Disc florets** 35–50+; corolla tubes 2.5–3.5 mm, limbs 3.5–4.5 mm. **Cypselae** 2.5–3.5+ mm long, glabrous, pappi 4.5–7 mm long. 2n=46.

Packera cana is found on open high plains and in sagebrush associations. It is also collected from dry rocky slopes and from crevices on both granitic and limestone outcrops. It flowers from late June into August, depending on latitude and elevation and is very abundant in Colorado. Although this species is found on grasslands in Wyoming, Montana, North Dakota, South Dakota, and Nebraska, it is rarely found on the high plains of the eastern part of Colorado.

Probably the only other species in Colorado with which it can be confused is *P. werneriifolia*. Two features contribute to this potential confusion: 1) At very high elevations *P. cana* may be very short (< 10 cm); 2) *P. werneriifolia* can be nearly as pubescent as *P. cana*.

There are two features distinguishing these two species: 1) *P. cana* nearly always has more than 3 heads in the inflorescence. At high elevations the inflorescence is often very compact, and the heads are small. *Packera werneriifolia*, on the other hand, normally has only 1 or two large heads. It can occasionally have 3–5 heads, in which case they are smaller than normal. 2) *P. cana* always has some cauline leaves even if they are very reduced and mostly on the lower portion of the stem, while *P. werneriifolia* is nearly always scapose, or in some very robust specimens, may have a few bract-like leaves on the stem.

Packera crocata (Rydb.) Weber & Löve, Phytologia. 49:46. 1981. *Senecio crocatus* Rydb.

Senecio aureus var. *croceus* A. Gray; *Senecio pyrrochrous* Greene; *Senecio tracyi* Rydb.

Perennials. **Caudices** long, stout, horizontal to ascending. **Stems** 2–6+ dm, single or rarely 2–3 clustered, glabrous. **Basal leaves** thin petiolate, blades narrowly lanceolate or ovate to oblong ovate, 2–6+ × 1–4+ cm, bases abruptly contracted

to tapering, margins subentire to crenate-dentate. **Cauline leaves** petiolate to sessile and weakly clasping, progressively reduced distally, lanceolate to oblong, margins sublyrate or lobed. **Heads** radiate, 7–15+ in open corymbiform arrays. Peduncles absent or small and inconspicuous, glabrous. **Calyculi** absent or few and small. **Phyllaries** 13 or 21, light green or with reddish tips, 4–8 mm, glabrous. **Ray florets** 8 or 13, corolla laminae 6–8+ mm, deep yellow to orange-red. **Disc florets** 60–80+; corolla tubes 4.5–5.5 mm, limbs 2.5–3.5 mm. **Cypselae** 1–1.5 mm long, glabrous, pappi 3–5 mm long. 2n=46.

This species grows in wet meadows often associated with grasses, sedges and willows, along trails and in rocky outcrops at middle to subalpine elevations and flowers from early July to mid-August. The only species that it may be confused with is *P. dimorphophylla* var. *dimorphophylla*. Three features distinguish these two species: 1) *P. crocata* has an open inflorescence, while that of *P. dimorphophylla* var. *dimorphophylla* is compact and congested. 2) *P. dimorphophylla* has dramatically large, auriculate, and conspicuously clasping middle and upper cauline leaves. While *P. crocata* may have larger than normal cauline leaves, they are at most weakly clasping. 3) While both species generally grow in wet places, *P. crocata* grows at elevations of ca. 8,000 – 10,000 feet and is fairly tall and thin, while *P. dimorphophylla* var. *dimorphophylla* is almost never found below 10,000 feet and is normally a more compact plant.

It is frequently noted in the literature that *P. crocata* has orange to reddish ray florets. However, *P. crocata* sometimes produces deep yellow ray florets, and *P. dimorphophylla* var. *dimorphophylla* may produce orangish ray florets.

Packera debilis (Nutt.) W.A. Weber & A. Löve, Phytologia. 49:46. 1981. *Senecio debilis* Nutt.

Senecio fedifolius Rydb.

Perennials. **Caudices** short, weakly branching. **Stems** 20–50+, single or 2–4 clustered, bases lightly floccose-tomentose or glabrous, leaf axils tomentose. **Basal leaves** petiolate and turgid, blades elliptic to ovate or subreniform, 2–4+ cm × 1.5–3+ cm, bases cuneate to subcordate, margins subentire or crenate to crenate-dentate. **Cauline leaves** petiolate to sessile, progressively reduced distally, blades pinnate-lobed, sinuses deep and rounded, lobes with entire to subentire margins. **Heads** eradiate, 6–20+ in open or compact corymbiform arrays. Peduncles present, short and conspicuous or absent, glabrous or lightly pubescent. **Calyculi** present, few and inconspicuous. **Phyllaries** 13 or 21, green with reddish tips, 6–8+ mm, glabrous. **Ray florets** absent. **Disc florets** 45–65+, corolla tubes 3–4 mm, limbs 2–3 mm. **Cypselae** 1–2 mm long, glabrous, pappi 4.5–5.5 mm long. 2n=46.

This is a distinctive plant of central and northern Colorado. It is collected frequently in Park County and less frequently in northern counties at mid to subalpine elevations in open meadows with alkaline soils. *Packera debilis* is sometimes identified as *P. pauciflora*, which is also a rayless plant with reddish

involucres. However, *P. pauciflora* is a plant with a more northerly distribution (it does not occur in Colorado) and a suite of characteristics that distinguish it from *P. debilis*. 1) *Packera debilis* generally has more than 6 heads in the inflorescence while *P. pauciflora* normally has 6 or fewer large heads. 2) *Packera debilis* has very short bracteoles on the peduncles, while *P. pauciflora* has very large conspicuous ones. 3) *Packera debilis*, has very few greenish, inconspicuous calyculate bracts. *P. pauciflora*, on the other hand, has long calyculate bracts that are normally quite reddish in color or at least have red tips. 4) The involucral bracts of *P. debilis* may display reddish coloration on the upper one-half to one-third of the tips, but the involucres of *P. pauciflora* are normally deeply anthocyanic throughout. 5) Probably the most easily distinguished characteristic concerns the lobing of the mid-cauline leaves. The terminal lobe of the leaves on *P. debilis* is narrow and pointed, and the sinuses of the individual lobes are deep and rounded.

Although *P. debilis* has been known at least from Park, Larimer, and Jackson counties for many years, it is very infrequently collected and is confined to alkaline meadow habitats. It may indeed be worthy of special note, and an effort should be made to document existing populations.

Packera dimorphophylla (Greene) var. **dimorphophylla** W.A. Weber & A. Löve, Phytologia. 49:46. 1981. *Senecio dimorphophyllus* Greene var. *dimorphophyllus*.

Perennials. **Caudices** short, stout, fibrous-rooted, horizontal to erect. **Stems** 1–3+ dm, single or rarely 2–3 clustered, simple or branched, glabrous. **Leaves:** basal leaves petiolate, thick and turgid, blades varying from ovate to subreniform or occasionally oblanceolate, bases tapering to a broad-winged petiole, margins entire to crenate; lower and mid-cauline leaves sessile, conspicuously clasping and auriculate, blades as large or larger than basal leaves, oblanceolate, obovate or lyrate, margins subentire to bluntly and irregularly dissected; upper cauline leaves usually reduced to sessile bracts, occasionally large and conspicuous. **Heads** radiate, 1–6+ in congested corymbiform or subumbellate arrays. Peduncles inconspicuously bracteolate or bracteoles absent, glabrous. **Calyculi** conspicuous, bases swollen. **Phyllaries** 13 or 21, occasionally fewer, green with anthocyanic apices, 5–7+ mm, glabrous. **Ray florets** 8 or 13, deep yellow to orange, corolla laminae 5–8+ mm. **Disc florets** 45–60+, corolla tubes 2–3 mm, limbs 2.5–3.5 mm. **Cypselae** 0.75–1.5 mm long, glabrous, pappi 3–4 mm long. 2n = 46.

This species is quite distinctive and is only rarely confused with one other entity in Colorado, *P. crocata*. A discussion of the characters used to separate the two species is found with the description of *P. crocata*. It is found at elevations generally over 10,000 feet in damp meadows or in seeps and crevices on hillsides. It flowers from early July to mid-August.

Packera fendleri (A. Gray) W.A. Weber & A. Löve, Phytologia. 49:46. 1981. *Senecio fendleri* A. Gray

Senecio nelsonii Rydb.; *Senecio salicinus* Rydb.; *Senecio canovirens* Rydb.; *Senecio rosulatus* Rydb.; *Senecio fendleri* var. *molestus* Greenm.

Perennials. **Caudices** rhizomatous, prominent lateral branches, horizontal to suberect. **Stems** 1–4+ dm, single or crowded to subcaespitose in some populations, floccose-tomentose or glabrescent. **Basal leaves** petiolate, blades lanceolate to oblanceolate, 3–6+ × 1–3+ cm, bases tapering, margins shallowly but evenly pinnatifid to pinnatisect or merely wavy, permanently floccose-tomentose or subglabrescent on upper surface. **Cauline leaves** sessile, gradually reduced distally, lanceolate to oblanceolate, margins pinnatisect to wavy. **Heads** radiate, 6–25+ in open or compact corymbiform arrays. Peduncles with numerous small bracteoles, heavily to irregularly floccose. **Calyculi** present but few and short, red tinged. **Phyllaries** 13, green, 5–7 mm, floccose proximally to glabrescent distally. **Ray florets** 6–8+, corolla laminae 5–7 mm. **Disc florets** 30–40+; corolla tubes 2.5–3 mm, limbs, 2.5–3.5 mm. **Cypselae** 2.5–3 mm long, glabrous, pappi 4–5 mm long. 2n=46.

This species is rarely confused with other Colorado Packeras. Some individuals, with merely wavy leaves could be mistaken for *P. cana*, but close inspection should easily separate the two. *Packera fendleri* is very abundant and almost weedy where it occurs. It prefers steep slopes in loose, dry rocky or gravelly soil, streamsides, open forested areas, and disturbed sites such as roadsides and picnic areas. It flowers any time between the end of May and early October throughout its range, depending on elevation.

Packera multilobata (Torr. & A. Gray ex A. Gray) W.A. Weber & A. Löve, Phytologia. 49:47. 1981. *Senecio multilobatus* Torr. & A. Gray ex. A. Gray

Senecio lynceus Greene; *Senecio nelsonii* var. *uintahensis* A. Nelson; *Senecio uintahensis* Greenm.; *Senecio stygius* Greene; *Senecio prolixus* Greenm.; *Senecio leucoreus* Greenm.; *Senecio thornberi* Greenm.

Perennials or biennials. **Caudices** weakly branching, taprooted, ascending to erect. **Stems** 2–4+ dm, single or 2–5 loosely clustered, glabrous or glabrescent, occasionally lightly tomentose throughout, axils of basal leaves with tufts of tomentum. **Leaves:** basal and lower cauline leaves petiolate, blades obovate, oblanceolate or spatulate, 4–8+ × 1–3+ cm, bases tapering, margins deeply pinnatifid or lyrate to sublyrate, leaf segments variously toothed and rounded; middle and upper cauline leaves progressively reduced distally, sessile. **Heads** radiate, 10–30+ in open corymbiform or subumbellate arrays. Peduncles conspicuously bracteolate, glabrous or with tufts of tomentum. **Calyculi** present and obvious. **Phyllaries** 13–21, green often with yellow tips, 4–9+ mm, glabrous to lightly tomentose proximally. **Ray florets** 8–13, corolla laminae 7–10 mm. **Disc florets** 40–50+, corolla tubes 4–5 mm, limbs 3–4 mm. **Cypselae** 2–3 mm long, glabrous or hirtellous on the angles, pappi 5–6 mm long. 2n = 46 or 92

This species is also rarely confused with any others in Colorado. *P.*

multilobata and *P. fendleri* are the only distinctly lobed or pinnatifid Packeras in the state. *Packera fendleri* is consistently very pubescent and *P. multilobata* is nearly always glabrous. *Packera multilobata* occurs on the western slope but thus far has not been recorded from counties along the Rocky Mountain Front. It prefers dry rocky or sandy substrates in habitats as varied as desert sagebrush, juniper woodlands, and subalpine forests. It flowers in early May at lower elevations and as late as mid-July at higher elevations.

Packera neomexicana (Greene) var. **mutabilis** W.A. Weber & A. Löve, Phytologia. 49:47. 1981. *Senecio mutabilis* Greene; *Senecio neomexicanus* var. *mutabilis* (Greene) T.M. Barkley.

Perennials. **Caudices** branched, weakly spreading, horizontal or ascending to erect. **Stems** 2–5+ dm, single or 2–3 clustered, densely lanate or arachnoid tomentose or glabrescent. **Basal leaves** petiolate, blades lanceolate or narrowly lanceolate, 2–6+ × 1–3+ cm, bases tapering, margins subentire to dentate, permanently but loosely tomentose throughout. **Cauline leaves** progressively reduced distally; lower leaves petiolate and similar to basal leaves; mid to upper cauline leaves becoming sessile, blades lanceolate, margins entire. **Heads** radiate, 3–20+ in open or compact corymbiform to subumbelliform arrays, subtended by smaller cymes arising from leaf axils. Peduncles conspicuously bracteolate, normally pubescent. **Caylculi** present and conspicuous. **Phyllaries** 13 or 21, green or yellowish, 4–7 mm, tomentose to glabrescent. **Ray florets** 8 or 13, occasionally 5, corolla laminae 4–10 mm. **Disc florets** 40–60+, corolla tubes 1.5–2.5 mm, limbs 3.5–4.5 mm. **Cypselae** 1.5–2.5 mm long, hirtellous on the angles or infrequently glabrous, pappi 5–6+ mm long. 2n = 46 or 92

This species flowers from late April to mid-July. It is frequently confused with *Packera tridenticulata*. Four characteristics, when taken in combination, can help to distinguish these two entities.

1) *P. tridenticulata* is a plant of the high plains and foothills in Colorado. In a few cases, it has apparently "jumped" the Rocky Mountain Front and has been collected growing in some of the interior valleys, usually in grassland/sagebrush associations. On the other hand, *P. neomexicana* var. *mutabilis* is generally found growing in rocky soils in open meadows and coniferous woodlands at high elevations.

2) *P. tridenticulata* usually grows in obvious clumps from a stout taprooted caudex, while *P. neomexicana* var. *mutabilis* normally has no more than 2–3 stems arising from a branching caudex.

3) *P. tridenticulata* tends to have slightly smaller achenes that are normally glabrous or at most lightly hirtellous along the angles, while *P. neomexicana* var. *mutabilis* has achenes that are a bit larger and normally distinctly hirtellous along the angles.

4) *P. tridenticulata* collected from the eastern part of its range is always glabrous. In the western part of its range, and in the interior valleys west of the Rocky Mountain Front, entities that would otherwise be easily identified as *P. tridenticulata* often show some very light pubescence at stem bases and in leaf axils. *Packera neomexicana* var. *mutabilis* is always loosely but persistently tomentose at least at the base of the stem, in the axils of the leaves, and at the base of the inflorescence. The lower leaf blades are also almost always lightly pubescent.

The center of distribution for *P. neomexicana* var. *mutabilis* is in the four-corners region, while *P. tridenticulata* is primarily a plant of the high plains and short-grass prairies. There is good evidence for hybridization between these two entities, primarily in the high valleys around Alamosa in south-central Colorado. There are several specimens in the herbaria at Adams State College in Alamosa and Colorado College in Colorado Springs with characters that are intermediate between *P. neomexicana* and *P. tridenticulata*. Several specimens display all the characteristics of *P. tridenticulata*, but are unusually and persistently tomentose, while others that are obviously glabrous have hirtellous achenes. Biosystematic work on these two species throughout the central valleys of Colorado would undoubtedly shed light on the complicated relationships in this complex.

Packera neomexicana var. *mutabilis* is infrequently confused, with *P. streptanthifolia* and *P. fendleri*. Some specimens of *P. fendleri* with merely wavy leaves and less than the normal amount of tomentum have been misidentified as *P. neomexicana* var. *mutabilis*. *Packera streptanthifolia* is a highly variable species with a number of identifiable "phases." The narrow-leaved phase of *P. streptanthifolia* is sometimes difficult to distinguish, but once again, careful observation of a combination of characters should provide accurate identifications.

Packera paupercula (Michx.) Löve & Löve, Bot. Not. 128:520. 1976. *Senecio pauperculus* Michx.

Senecio balsamitae Muhl. ex Willd.; *Senecio flavovirens* Rydb.; *Senecio crawfordii* Britton; *Senecio tweedyi* Rydb.; *Senecio multnomensis* Greenm.; *Senecio gaspensis* Greenm.

Perennials. **Caudices** sub-rhizomatous, weakly branching, ascending to erect. **Stems** 2–4.5+ dm, single or 2–4 loosely clustered, glabrous or lightly tomentose proximally. **Leaves**: basal leaves petiolate, blades lanceolate to narrowly elliptic or oblanceolate, 3–6+ × 1–2+ cm, bases tapering to cuneate or obtuse, margins subentire to variously dentate or serrate. Cauline leaves progressively reduced distally; lower ones petiolate, blades sublyrate; middle ones sessile, blades lanceolate, margins variously dissected, incised or lacerate; upper ones sessile bracts. **Heads** radiate, 2–10+ in loose or compact corymbiform arrays. Peduncles bracteolate or bracteoles occasionally absent, glabrous. **Calyculi** present and inconspicuous. **Phyllaries** 13 or 21, green, 5–8+ mm, glabrous. **Ray florets** 8 or 13, or occasionally absent, corolla laminae 5–10+ mm. **Disc florets** 50–65+, corolla

tubes 2–3 mm, limbs 2–3 mm. **Cypselae** 1–2 mm long, glabrous or occasionally hispidulous on the angles, pappi 3.5–4.5 mm long. 2n = 44 or 46.

Packera paupercula is the most ecologically and morphologically variable *Packera* in North America. Although widespread, it has been infrequently collected in Colorado. It flowers from late June to late July in Colorado and can be found in wet meadows, open woodlands, and along streambanks. In areas of sympatry, *P. paupercula* can be confused with *P. plattensis*, but that is not a problem in Colorado because *P. plattensis* is confined to the high plains and *P. paupercula* has only been collected from mountainous regions.

The other species with which *P. paupercula* could easily be confused is *P. pseudaurea* var. *flavula*. There are six characteristics that can be used in combination to separate these two entities: 1) Basal and lower leaf blades of *P. paupercula* are lanceolate to narrowly elliptic, and normally 1.5–3 times longer than wide. Those of *P. pseudaurea* var. *flavula* are broadly lanceolate to ovate, and 1–2 times longer than wide; 2) Bases of the leaf blades of *P. paupercula* are tapering, those of the *P. pseudaurea* var. *flavula* are truncate to subcordate; 3) Upper cauline leaves of the former are sessile, those of the latter are weakly clasping; 4) Phyllaries of *P. paupercula* specimens from Colorado normally number 13 and are 5–8 mm long, those of *P. pseudaurea* var. *flavula* usually number 21 and are 3–5 mm long; 5) *P. paupercula* normally has 40–50 disc florets in a one head, *P. pseudaurea* var. *flavula* has 60–80; 6) Corolla tubes of the disc florets in *P. paupercula* are about the same length as the limbs, 2–3 mm, however in *P. pseudaurea* var. *flavula*, the corolla tubes are much longer than the limbs, 3.5–4.5 mm and 2–3 mm, respectively.

Packera plattensis (Nutt.) W.A. Weber & Löve, Phytologia. 49:48. 1981. *Senecio plattensis* Nutt.

Senecio pseudotomentosus Mackenzie & Bush.

Perennials or biennials. **Caudices** stoloniferous in eastern populations, fibrous rooted elsewhere, erect or suberect. **Stems** 2–6+ dm, single or 2–3 clustered, persistently floccose-tomentose proximally and in leaf axils, lightly tomentose or glabrescent elsewhere. **Leaves:** basal and lower cauline leaves petiolate, blades narrowly elliptic to elliptic-ovate or oblanceolate to suborbicular, abaxial surface subpersistently floccose-tomentose, especially along the mid-vein, 2–7+ × 1–3+ cm, bases tapering to rounded or abruptly contracted, margins subentire to crenate, serrate-dentate, or sublyrate; middle cauline leaves progressively reduced distally, short petiolate, blades sub-lyrate to pinnatisect, lightly pubescent on the abaxial surface; upper cauline leaves, sessile, subentire to irregularly dissected. **Heads** radiate, 6–20+ in open or congested corymbiform arrays. Peduncles abundantly bracteolate, lightly to heavily tomentose. **Calyculi** numerous but inconspicuous. **Phyllaries** 13 or 21, green or occasionally with reddish tips, 5–6+ mm, densely tomentose distally, glabrescent above. **Ray florets**

8–10, corolla laminae 9–10 mm. **Disc florets** 60–70+, corolla tubes 2.5–3.5 mm, limbs 3.5–4.5 mm. **Cypselae** 1.5–2.5 mm long, hirtellous or occasionally glabrous, pappi, 6.5–7.5 mm long. 2n = 46 or 92.

Packera plattensis inhabits rocky, gravelly, or sandy/loam soils in open prairies and grasslands. It is found throughout eastern Colorado but in dry years may not be abundant. It occurs in the foothills of the Front Range, but to my knowledge has never been collected further west than that. *Packera plattensis* flowers from mid-May to mid-June in Colorado. The only other high plains *Packera* species in Colorado is *P. tridenticulata*, and these two species are rarely confused. *Packera plattensis* is always densely floccose-tomentose at the base of the stem and in the leaf axils and often persistently lightly tomentose elsewhere. *Packera tridenticulata* collected on the high plains is nearly always glabrous or at most very lightly tomentose at the base of the stem.

Packera porteri (Greene) C. Jeffrey, Kew Bull. 47:101. 1992. *Senecio porteri* Greene; *Ligularia porteri* (Greene) W.A. Weber

Senecio renifolius Porter; *Senecio aureus* var. *alpinus* A. Gray.

Perennials. **Caudices** with long slender branching rhizomes. **Stems** 3–10+ cm, single, often anthocyanic, glabrous. **Leaves**: basal leaves petiolate and turgid, blades reniform to sub-reniform, 0.5–1.5+ × 0.5–2.5+ cm, abaxial surface distinctly anthocyanic, bases abruptly contracted to cordate, margins distinctly crenate or occasionally wavy; cauline leaves abruptly reduced distally to 1–4 sessile bracts with entire margins. **Heads** radiate, 1 large terminal head, 10–15+ mm high. **Calyculi** present and conspicuous, often anthocyanic. **Phyllaries** 13 or 21, deep red, 8–10+ mm, glabrous. **Ray florets** 8 or 13, corolla laminae 8–10+ mm. **Disc florets** 40–50+, corolla tubes 2.5–3.5 mm, limbs 2.5–3.5 mm. **Cypselae** 1.5–2.5 mm long, glabrous, pappi 4–5.5 mm long.

Packera porteri is undoubtedly the most morphologically distinctive *Packera* in Colorado and the most restricted in range and habitat. It is confined to steep talus slopes in alpine habitats, rarely below 11,000 feet. It is most frequently collected west of the Continental Divide in two general locations: Gunnison and nearby counties, in the Elk Mountains around Gothic and in Maroon Bells/Snowmass Wilderness areas; and in San Juan and Hinsdale counties. However, it has also been collected east of the divide in Chaffee County. Due to its diminutive form and remote location, it may have been overlooked elsewhere. *Packera porteri* flowers from mid-July to mid-August.

Packera pseudaurea (Greene) var. **flavula** D.K. Trock & T.M. Barkley, Phytologia. 49:48. 1981. *Senecio pseudaureus* var. *flavulus* (Greene) Greenm.; *Senecio flavulus* Greene.

Perennials. **Caudices** simple or branched, fibrous-rooted, horizontal to erect. **Stems** 2–5+ dm, thin and slender, single or occasionally 2–4 clustered, glabrous or lightly tomentose proximally. **Leaves**: basal leaves petiolate, blades broadly

lanceolate to ovate or occasionally sub-hastate, 2–4+ × 2–3+ cm, bases truncate to subcordate or obtuse, margins bluntly dentate or denticulate, rarely sharply toothed; lower cauline leaves petiolate, blades sublyrate to lacinate or occasionally subentire; middle and upper cauline leaves progressively reduced distally, becoming sessile, occasionally clasping. **Heads** radiate, 5–12+ heads in a congested cyme. Peduncles inconspicuously bracteolate, glabrous. **Calyculi** present. **Phyllaries** 21 or occasionally 13, rarely 30 or more, light green, 3–6 mm, glabrous. **Ray florets** 8 or 13, corolla laminae 6–10+ mm, or occasionally absent. **Disc florets** 60–80+, corolla tubes 3.5–4.5 mm, limbs 2–3 mm. **Cypselae** 1–1.5 mm long, glabrous, pappi 4.5–5.5 mm long. 2n = 46

This variety of *P. pseudaurea* is found in the southern Rocky Mountains and is most abundant in Colorado. It inhabits the same habitat type as *P. paupercula*, and its gross morphology is similar. The comments following the description of *P. paupercula* provide a suite of six characteristics that can be used to distinguish the two entities. *Packera pseudaurea* var. *flavula* flowers from late May to early July. Where the two occur at similar elevations and in similar habitats, *P. pseudaurea* var. *flavula* usually flowers about one month earlier than *P. paupercula*.

Packera streptanthifolia (Greene) W.A. Weber & Löve var. **streptanthifolia**
Phytologia. 49:48. 1981. *Senecio streptanthifolius* Greene; *Senecio cymbalarioides* var. *streptanthifolius* (Greene) Greenm.

Senecio cymbalarioides Nutt.; *Senecio streptanthifolia* var. *laetiflorus* (Greene) J.F. Bain; *Senecio streptanthifolius* var. *rubricaulis* (Greene) J.F. Bain; *Senecio cognatus* Greene; *Senecio wardii* Greene; *Senecio adamsi* Howell; *Senecio suksdorfii* Greenm.; *Senecio longipetiolatus* Rydb.; *Senecio fulgens* Rydb.; *Senecio rydbergii* A. Nelson; *Senecio jonesii* Rydb.; *Senecio subcuneatus* Rydb.; *Senecio platylobus* Rydb.; *Senecio streptanthifolius* var. *oodes* (Rydb.) J.F. Bain; *Senecio oodes* Rydb.; *Senecio leonardii* Rydb.; *Senecio streptanthifolius* var. *kluanei* J.F. Bain; *Senecio streptanthifolius* var. *wallowensis* J.F. Bain.

Perennials. **Caudices** weak to stout, fibrous-rooted, horizontal to suberect. **Stems** 2–4+ dm, single or 2–5 clustered, glabrous or occasionally lightly floccose tomentose proximally and in leaf axils. **Leaves:** basal and lower cauline leaves, petiolate, thick and turgid, blades varying from oblanceolate or ovate to orbicular, 2–4+ × 1–3+ cm, bases tapering or abruptly contracted, margins entire, crenate, dentate or weakly lobulate, normally glabrous or sometimes persistently pubescent; middle and upper cauline leaves gradually reduced distally, becoming sessile, margins entire to sub-entire. **Heads** radiate, 6–15+ in loose corymbiform or subumbellate arrays. Peduncles variably bracteolate, glabrous or lightly tomentose. **Calyculi** present and conspicuous. **Phyllaries** 13 or 21, occasionally 8, green or with anthocyanic tips, 4–7+ mm, glabrous. **Ray florets** 8 or 13, corolla laminae 5–10 mm. **Disc florets** 35–60+, corolla tubes 2–4 mm, limbs 2.5–4 mm. **Cypselae** 1–2.5 mm long, glabrous, pappi, 3–6 mm long. 2n = 46.

Packera streptanthifolia grows in a wide variety of habitats, from forested

areas to open meadows and valleys and in soils ranging from dry and rocky to damp and loamy. It also occurs at a wide range of elevations, from 6500 feet to above timberline. The species is complex and has been divided by some researchers (Bain 1983, 1988) into as many as seven distinct taxa—five species and two varieties or two species and five varieties. This author recognizes only one species and two varieties, while acknowledging that there is a great amount of morphological variation. There is less morphological variation within this species in Colorado than there is in other parts of its range.

The narrow-leaved phase of *P. streptanthifolia* could superficially be confused with *P. neomexicana* var. *mutabilis*. However, the former has glabrous achenes, while achenes of the latter are normally hirtellous. *Packera streptanthifolia* in Colorado normally has leaves that are ovate to orbicular. Probably the most reliable characteristics are the thick and turgid leaf blades, and a very stout fibrous-rooted caudex. In Colorado, this species flowers from early June to early July at lower elevations and from mid-July to mid-August at high elevations.

Packera tridenticulata (Rydb.) W.A. Weber & Löve, Phytologia. 49:48. 1981. *Senecio tridenticulatus* Rydb.

Senecio compactus Rydb.; *Senecio densus* Greene; *Senecio oblanceolatus* Rydb.; *Senecio acutidens* Rydb.; *Senecio manitobensis* Greenm.; *Senecio remifolius* Wooton & Standley.

Perennials. **Caudices** taprooted, ascending to erect. **Stems** 1–3+ dm, single or frequently several clustered, glabrous or rarely lightly floccose-tomentose, often with tufts of tomentum in leaf axils. **Leaves:** basal and lower cauline leaves petiolate, blades thick and turgid, lanceolate or narrowly oblanceolate, 2–4+ × 0.5–1.5 cm, bases tapering, margins entire, subentire or dentate at the apex, occasionally sub-pinnatisect; middle and upper cauline leaves gradually or progressively reduced distally, becoming sessile. **Heads** radiate, 4–15+ heads in corymbiform arrays. Penduncles bracteolate, glabrous to lightly tomentose. **Calyculi** numerous but small. **Phyllaries** 13–21, green, 6–10 mm, sparsely tomentose proximally, glabrous distally. **Ray florets** 8–10 or occasionally 13, corolla laminae 5–8+ mm. **Disc florets**, 45–60+, corolla tubes 3–3.5 mm, limbs 4–5 mm. **Cypselae** 1.5–2.5 mm long, glabrous or lightly hirtellous on the angles, pappi 5–6 mm long. 2n = 46.

This species can be found in shortgrass prairies or sagebrush scrub habitats, growing in dry gravelly or sandy soils. It is primarily a plant of the central High Plains, but its range extends into the foothills of the Rockies and into some of the high valleys west of the Rocky Mountain Front in Colorado. It tends to grow in clumps with several stems arising from a single taprooted, woody caudex. The only other species in Colorado with which it may be confused is *P. neomexicana* var. *mutabilis*. That relationship is discussed in detail under *P. neomexicana*. *Packera tridenticulata* flowers from late May to early July.

Packera werneriifolia (A. Gray) W.A. Weber & Löve, Phytologia 49:48. 1981. *Senecio werneriaefolius* A. Gray.

Senecio saxosus Klatt; *Senecio petrocallis* Greene; *Senecio scaposus* A. Nelson; *Senecio perennans* A. Nelson; *Senecio muirii* Greenm.; *Senecio molinarius* Greenm.

Perennials. **Caudices** branching, sub-rhizomatous, sometimes several densely crowded and caespitose. **Stems** 7–15+ cm, single or 3–5 clustered, floccose or lanate-tomentose, canescent or occasionally glabrate. **Basal Leaves** sessile or with very short petioles, blades narrowly lanceolate to elliptic, 1.5–4+ × 0.5–2.5 cm, bases tapering, margins entire or dentate toward the apex, frequently revolute; or in some populations petiolate with blades ovate to orbicular, 1–2 × 0.5–1.5 cm, bases tapering to abruptly contracted, margins entire or wavy, occasionally dentate toward the apex. **Cauline leaves** reduced to mere bracts, plant with a scapose aspect. **Heads** radiate, 1–5 or in some populations 3–8. Peduncles inconspicuously bracteolate, glabrous to densely pubescent. **Calyculi** conspicuous, frequently anthocyanic. **Phyllaries** 13 or 21, green or with anthocyanic apices, 4–10 mm, glabrous to pubescent. **Ray florets** 8 or 13, corolla laminae 5–10 mm; or occasionally absent. **Disc florets** 30–50+, corolla tubes 2.5–3.5 mm, limbs 3–4 mm. **Cypselae** 1.5–2 mm long, glabrous, pappi 5–6 mm long. 2n = 44 or 46.

This species grows on rocky talus slopes or in sandy soil in forest openings near or above timberline. Flowering time varies greatly with elevation but is generally from mid-June to mid-August. Some specimens have basal leaf blades that are sessile and very narrow, while the basal leaves of others are petiolate and more ovate in outline. Some specimens are densely tomentose, while others are only lightly pubescent, even glabrate. But the feature that all of the specimens have in common is their scapose aspect.

The only species in Colorado with which it could be confused is *P. cana*, and that relationship is discussed in detail under the comments for *P. cana*.

ACKNOWLEDGMENTS

I am grateful to Ted Barkley, Guy Nesom, and Ron Hartman for their comments and helpful suggestions. I would also like to thank Catherine Kleier and Tass Kelso for providing their insights on the Colorado flora and for their assistance with herbarium specimens. Thanks also go to all of the institutions mentioned in this paper for their loan of specimens.

BOOK NOTICES

ELIZABETH SILVERTHORNE. 2002. **Legends and Lore of Texas Wildflowers.** (ISBN 1-58544-230, pbk.). Texas A&M University Press, John H. Lindsey Bldg., Lewis St. 4354 TAMU, College Station, TX 77843-4354, U.S.A. (Orders: wlawrence@tamu.edu, http://www.tamu.edu/upress, 800-826-8911). $24.95 hbk., $16.95 pbk., 264 pp., 18 line drawings, Bib. Index, 7" × 9".

Forty-four Texas wildflowers are discussed in this book. Their botanical names as well as their common names are given, and stories about the origins and lore surrounding them are the focus. This is not a field guide or identification book, but rather a collection of interesting tales about these particular flowers.

The author does deal with the habitats, descriptions, uses—medicinal and otherwise—of the plants, and tells something of the early botanists. In fact it is crammed with information told in non-technical terms. Some of the flowers are illustrated, although the artist is not credited. It is a pleasant addition to the literature of wildflowers.—*Ruth Ginsburg, Botanical Research Institute of Texas, Fort Worth, TX, U.S.A.*

ROY L. LEHMAN, RUTH O'BRIEN, and TAMMY WHITE. 2002. **Plants of Webb County, Texas.** (ISBN not given, pbk.). Texas A&M University-Corpus Christi, Dept. of Physical and Life Sciences, 6300 Ocean Drive, Corpus Christi, TX 78412, U.S.A. (Orders: 512-994-2754, fax 512-994-2742). Price not given, 47 pp., numerous color photos, 1 map, index, 5 1/2" × 8 1/2".

According to the foreword, "This booklet was first designed to be a guide for secondary school, college students and for the laymen interested in flowers and plants found on the Galvan Ranch." It was decided that, as the ranch was no longer accessible to the general public, that the guide be reformatted and titled to include common and interesting plants from the county [Webb]."

Each of the species covered in the book includes a color photograph, common name(s), Latin name and some synonyms, followed by a brief description including habitat and flowering time. The authors are to be congratulated for all the hard work on this book. It is especially nice because of the lack of floras for that part of Texas. A big thank you goes to the Ed Rachel Foundation in Corpus Christi for their financial support of the project. The Foundation's support of research on Texas native plants is truly appreciated; what an incredible gift to the people of Webb County and Texas.—*Barney Lipscomb, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX 76102-4060, U.S.A., barney@brit.org.*

NOMENCLATURAL COMBINATIONS IN NORTH AMERICAN *PANICUM* SUBGENUS *DICHANTHELIUM* AND SUBGENUS *AGROSTOIDES* (POACEAE: PANICEAE)

Joseph K. Wipff

Herbarium

Pure Seed Testing, Inc.
Canby, OR 97013, U.S.A.

ABSTRACT

The new combinations made here are: *Panicum aciculare* var. *ramosum*; *Panicum aciculare* var. *neuranthum*; *Panicum acuminatum* var. *ferventicola*; *Panicum acuminatum* var. *thermale*; *Panicum commutatum* var. *equilaterale*; *Panicum ovale* var. *praecocius*; and *Panicum rigidulum* var. *abscissum*.

RESUMEN

Se hacen las siguientes nuevas combinaciones: *Panicum aciculare* var. *ramosum*; *Panicum aciculare* var. *neuranthum*; *Panicum acuminatum* var. *ferventicola*; *Panicum acuminatum* var. *thermale*; *Panicum commutatum* var. *equilaterale*; *Panicum ovale* var. *praecocius*; y *Panicum rigidulum* var. *abscissum*.

The debate over whether *Dichanthelium* should be recognized as a segregate genus from *Panicum* or as a subgenus of *Panicum* will probably never be resolved, with both 'camps' having data to support their views. It is a debate that I will not get into here, but will only provide references for both treatments, so the reader can form their own opinion. Gould (1974), Clark and Gould (1975), Gould and Clark (1978), Gould (1980) and Giussani et. al (2001) support the recognition of *Dichanthelium* as a segregate genus. Whereas, Pohl (1980), Lelong (1984), Zuloaga (1987), Morrone and Zuloaga (1991), Zuloaga et al. (1991) and Zuloaga et al. (1993) support the recognition of *Dichanthelium* as a subgenus of *Panicum*; a classification with which I also agree.

Freckmann and Lelong (2002) published fifty-two new combinations in *Dichanthelium* and *Panicum* while preparing their treatment for Volume 25 of *The Flora of North America* (Barkworth et al. [eds.], in press). Some of the taxa treated in *Dichanthelium* by Freckmann and Lelong (2002) do not have an available name in *Panicum*, which are required for use in the *Vascular Plants of Texas: A Comprehensive Checklist including Synonymy, Bibliography, and Index* (Jones et al. 1997), revision in progress, as well as, for on going work on *Panicum* subg. *Dichanthelium* in North America. In addition, *Panicum abscissum* Swallen is recognized at the rank of variety and not subspecies, following the treatment of *Panicum rigidulum* by Lelong (1984), since no data were presented in Freckmann

SIDA 20(3): 1043–1046. 2003

and Lelong (2002) warranting the treatment of these taxa at the subspecific rank.

Panicum aciculare Desvaux ex Poiret var. **ramosum** (Griseb.) Wipff, comb nov.
BASIONYM: *Panicum neuranthum* Griseb. var. *ramosum* Griseb., Cat. pl. Cub. 232. 1866. *Panicum fusiforme* Hitchc., Contr. U.S. Natl. Herb. 12:222. 1909. *Dichanthelium fusiforme* (Hitchc.) Harvill, Castanea 42:177. 1977. *Dichanthelium aciculare* var. *ramosum* (Griseb.) Davidse, Novon 2:104. 1992. *Dichanthelium aciculare* Desvaux ex Poiret subsp. *fusiforme* (Hitchc.) Freckmann & Lelong, Sida 20:167. 2002. TYPE: CUBA: western Cuba, 1863, *C. Wright 3454* (HOLOTYPE : GOET, fragment US).

Panicum aciculare Desvaux ex Poiret var. **neuranthum** (Griseb.) Wipff, comb et stat. nov. BASIONYM: *Panicum neuranthum* Griseb., Cat. pl. Cub. 232. 1866. *Dichanthelium aciculare* Desvaux ex Poiret subsp. *neuranthum* (Griseb.) Freckmann & Lelong, Sida 20:167. 2002. TYPE: CUBA: eastern Cuba, 1860, *C. Wright 3453* (HOLOTYPE : US).

Panicum acuminatum Sw. var. **ferventicola** (Schmoll) Wipff, comb. et stat. nov.
BASIONYM. *Panicum ferventicola* Schmoll, Madroño 5:92. 1939; and the autonym created by *Panicum ferventicola* var. *papillosum* Schmoll, Madroño 5:94 and *Panicum ferventicola* Schmoll var. *sericeum* Schmoll, Madroño 5:92. 1939. PERFORATION PLATE DIVERSITY IN *ILLICIUM FLORIDANUM* (ILLICIACEAE) WITH RESPECT TO ORGANS, PROVENANCE, AND MICROTECHNICAL METHODS

Edward L. Schneider and Sherwin Carlquist

Santa Barbara Botanic Garden
1212 Mission Canyon Road
Santa Barbara, CA 93105, U.S.A.

ABSTRACT

Pit membrane remnants in scalariform perforations of mature *Illicium floridanum* vessels of stems and roots from three sources were studied with scanning electron microscope (SEM). Several methods of preservation and microtechnical treatment were used; results for all of these methods, for the three sources, and for the two organs revealed similar patterns. The perforation pit membranes illustrated are believed to be relatively free of artifacts. Pit membrane presence in perforations of all collections of *I. floridanum* studied ranges from intact non-porose pit membranes to near absence of any pit membrane fragments. However, the extreme conditions are relatively infrequent, and the most common condition is presence of less than 50% of the pit membrane; presence of more than 50% of the pit membrane is somewhat less common. The phylogenetic significance of pit membrane presence in perforations is considered a symplesiomorphic feature for angiosperms. Presence of pit membrane remnants in perforations is valuable in phylogenetic analyses of angiosperms.

KEY WORDS: basal angiosperms, Illiciales, perforation plates, pit membrane remnants, tracheid-vessel transition, vessel evolution, wood evolution.

RESUMEN

Se estudiaron al microscopio electrónico de barrido (SEM) restos de las membranas de punteaduras de las perforaciones escalariformes de vasos de tallos y raíces de *Illicium floridanum* maduros procedentes de tres fuentes. Se usaron varios métodos de conservación y tratamientos microtécnicos; obteniendo patrones similares con todos los métodos, para las tres fuentes y los dos órganos. Las perforaciones de las membranas de las punteaduras que se ilustran se cree que no tienen artefactos. La presencia de punteaduras de membrana en las perforaciones de todas las colecciones de *I. floridanum* estudiadas varían desde punteaduras intactas no-porosas hasta la casi ausencia de fragmentos de membrana. Sin embargo, las condiciones extremas son relativamente infrecuentes, y las condiciones más comunes son la presencia de menos del 50% de membrana de la punteadura; la presencia de más del 50% de la membrana de la punteadura es algo menos frecuente. El significado filogenético de la presencia de la membrana de la punteadura en las perforaciones se considera una característica simplesiomorfica en angiospermas. La presencia de restos de la membrana de la punteadura en las perforaciones es valiosa en los análisis filogenéticos en angiospermas.

INTRODUCTION

Presence of pit membrane remnants in perforations of primitive woody dicotyledons with scalariform perforation plates was figured by Meylan & Butterfield (1978) for several species of New Zealand woods, such as *Ascarina lucida* Hook.f., *Carpodetus serratus* J.R. & G. Forst., *Quintinia acutifolia* Kirk, and *Weinmannia*

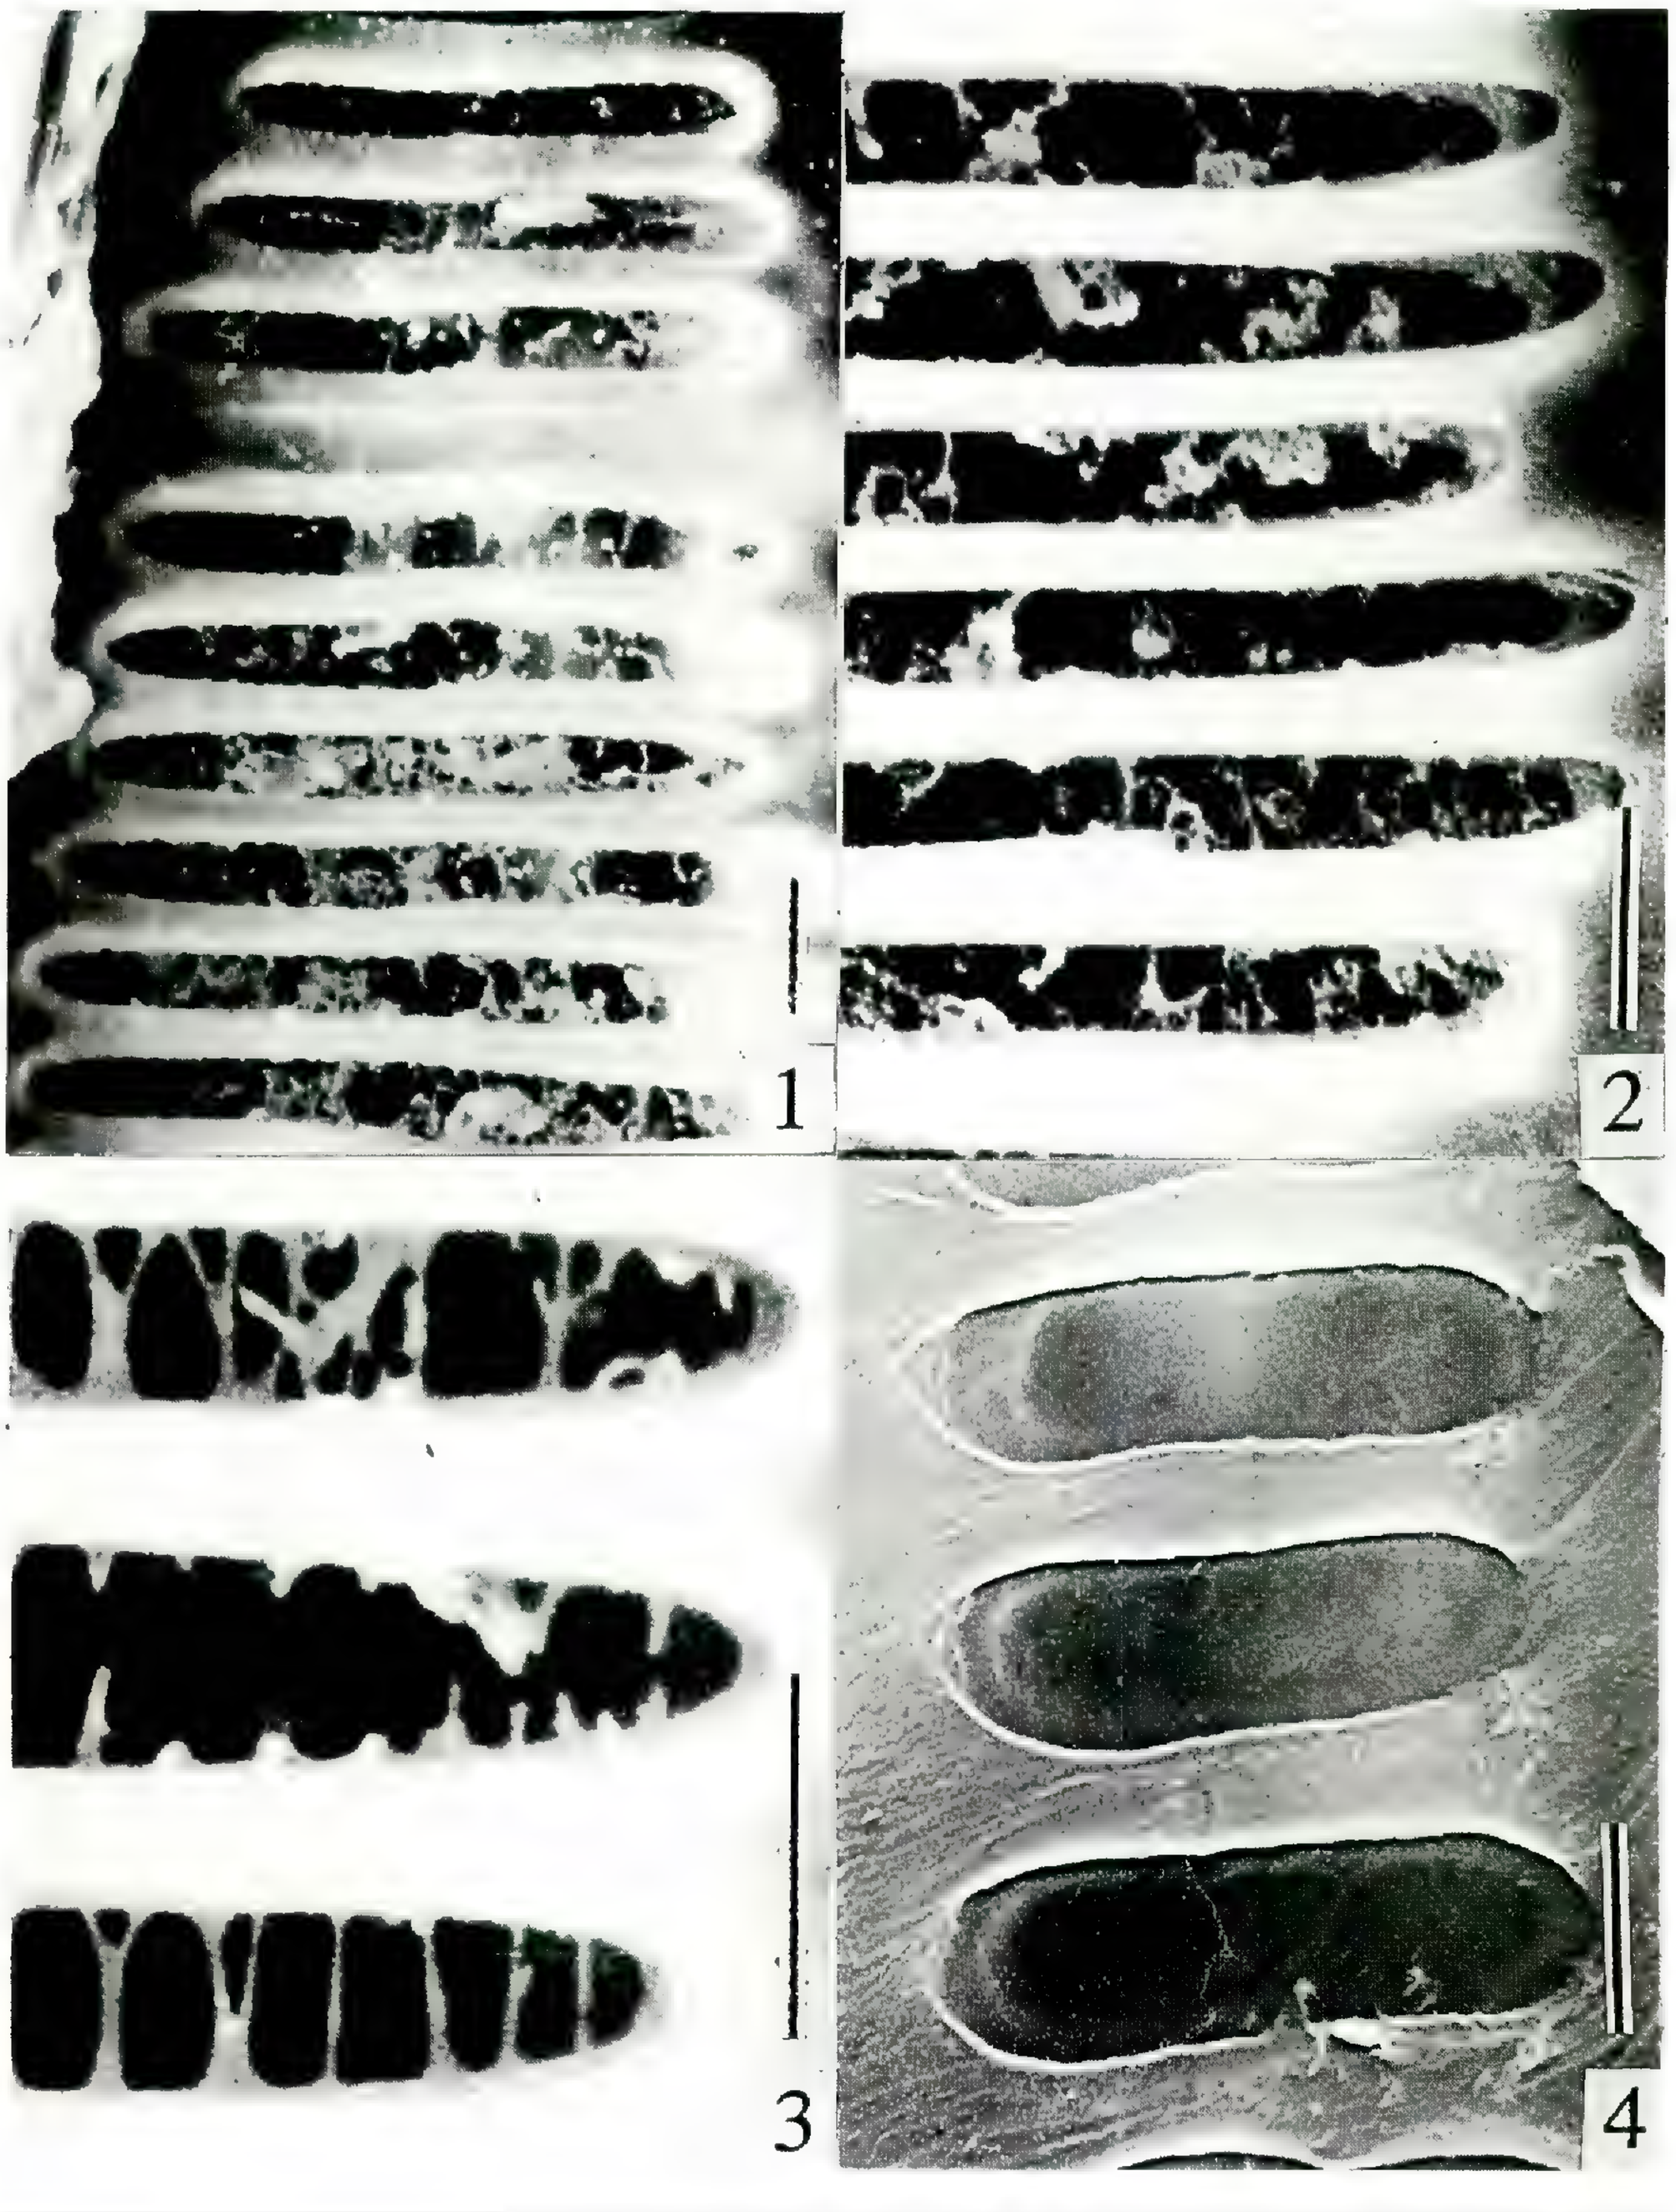
racemosa L.f. Similar figures were presented by Takahashi (e.g., 1985). Meylan and Butterfield (1978) refer to threadlike pit membrane remnants as "microfibrillar webs," and in some cases this describes the appearances well. In others (*Ascarina*, *Weinmannia*), the pit membranes look essentially intact; they contain circular pores of various sizes. Pit membrane remnants in a simple perforation plate of *Knightia* (Proteaceae) were figured by Butterfield and Meylan (1982).

In a review of this phenomenon (Carlquist 1992a), the term "pit membrane remnants" was proposed to describe the diversity of pit membranes or membrane portions that occur as threads as well as those that occur as persistent sheets in which component microfibrils are not evident. Pit membrane remnants occur in a number of dicotyledon families (Carlquist 1992a) as well as in some monocotyledons (see illustrations and literature cited in Carlquist & Schneider 1997, 1998; Schneider & Carlquist 1998) and ferns (Carlquist & Schneider 2001 and literature cited therein).

Pit membrane remnants appear characteristic of particular families, such as Chloranthaceae (Carlquist 1990, 1992b, 1992c). Among the families that currently constitute Illiciales, pit membrane remnants are most conspicuous in *Illicium* (Carlquist 1992b; Carlquist & Schneider 2002b), sole genus of Illiciaceae, as well as in the monospecific family Austrobaileyaceae (Carlquist 2001) and both genera of Schisandraceae (Carlquist 1999). The survey of the genus *Illicium* with respect to pit membrane remnants (Carlquist 1992a) showed diversity but not the causes for this diversity. Conceivably, the sources for different degrees and types of pit membrane remnant presence in *Illicium* can be related to differences among species, differences in provenance, differences among parts of a single plant, or differences in methods of preparation. The present paper has selected one readily available species, *Illicium floridanum* Ellis, because pit membrane remnants in perforations appeared abundant and varied on the basis of preliminary observations (Carlquist 1992a), and because material of living plants is readily available.

An understanding of the diversity of pit membrane remnants in *Illicium floridanum* is needed as a baseline against which to compare diversity in such remnants in other dicotyledons. Do pit membrane remnants indicate a primitive character state in phylads of angiosperms as suggested by Carlquist (1992a)? Can degrees of pit membrane presence be indicative of departure from tracheid-like tracheary elements, and if so, can these degrees be used cladistically and can they help us understand the nature of the tracheid-vessel element transition (Carlquist & Schneider, in press)?

MATERIAL AND METHODS



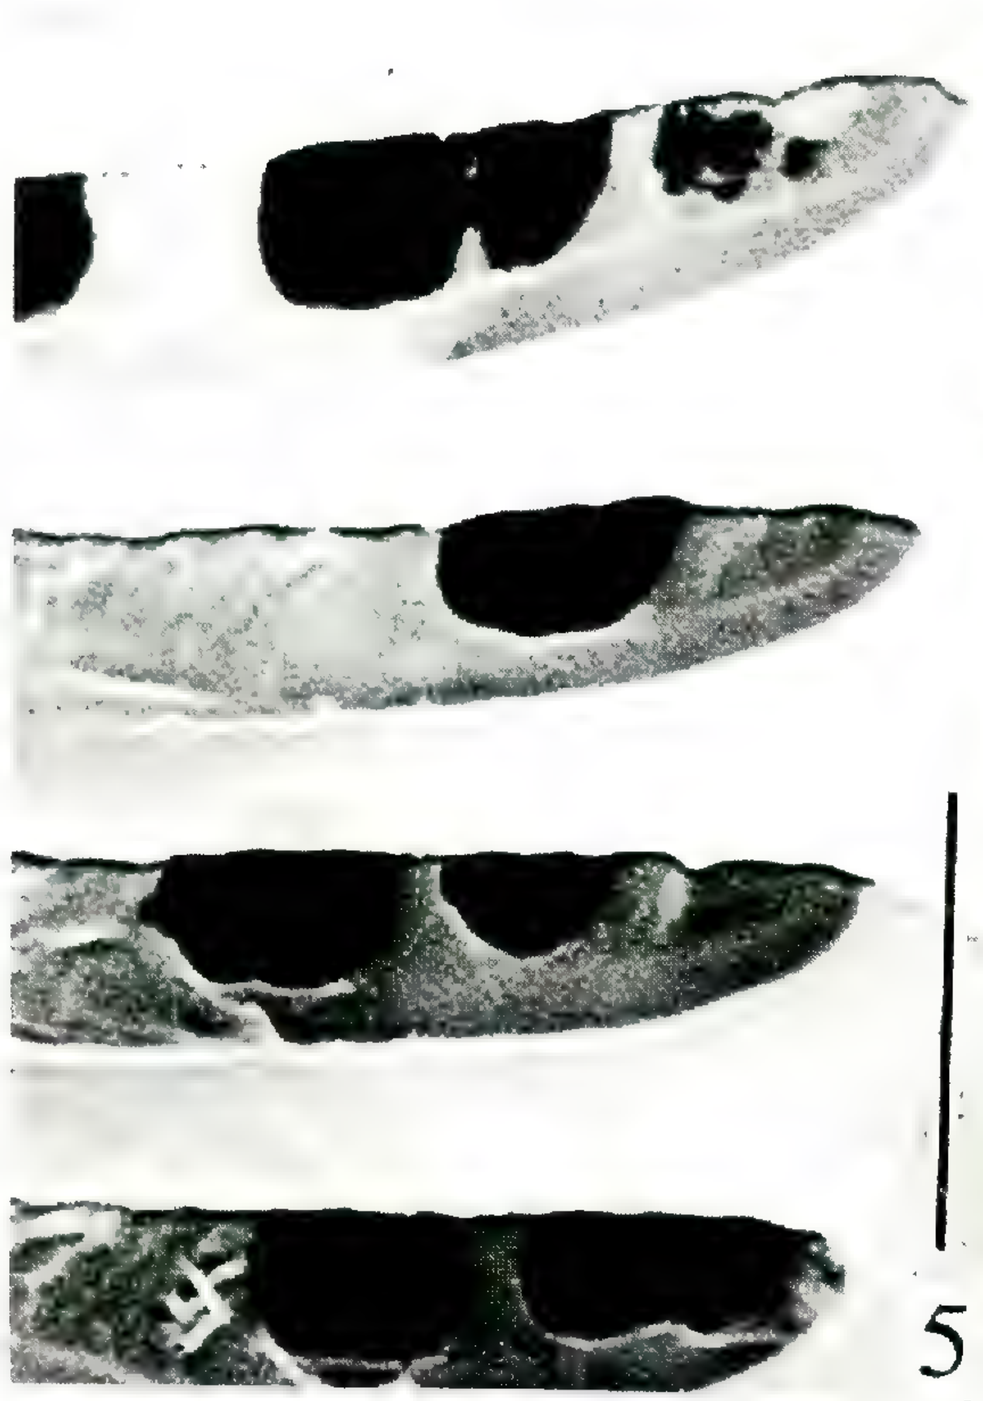
The dried *Illicium floridanum* stem (Palmer 19768; "Florida" without further locality) was derived from a specimen 12 mm in transectional diameter in the

RSAw collection. This specimen had been donated to Rancho Santa Ana Botanic Garden by the U.S. National wood collection (USw). A portion of this specimen was boiled in water, stored in 50% aqueous ethanol, and sectioned on a sliding microtome. Some of the sections were dried between clean glass slides, sputter coated with gold and examined with an ISI WB-6 scanning electron microscope (SEM) at Rancho Santa Ana Botanic Garden. Living stems (8 mm in diameter) of the species were obtained from a cultivated plant in the lathhouse at University of California, Santa Barbara, and were preserved in 50% aqueous ethanol. A stem 5 mm in diameter was obtained from the University of Florida, Gainesville. Living roots of the species (10 mm in diameter) were provided by the U.S. National Arboretum, Washington, D.C., and were preserved in 50% aqueous ethanol. Root and stem portions from living specimens were preserved in alcohol without the use of any other reagents in order to minimize artifact formation in the pit membranes of perforation plates. Critical-point drying was not employed because in mature woods, many vessels are already filled with air and critical-point drying would be redundant (Butterfield & Meylan 1982). The stems and roots derived from living specimens were sectioned on a sliding microtome (only radial sections were prepared). Sections were dried between glass slides, sputter-coated with gold, and observed with a Bausch & Lomb Nanolab 200 SEM at Santa Barbara Botanic Garden. Thick sections (ca. 50 μm) were cut in order to obtain complete sheets extending from cambium to pith rather than fragmentary sections. Thick sections offer no disadvantage where SEM is involved. Thick sections, on the contrary, are more likely than thin sections to have long portions of perforation plates or even entire perforation plates.

Low accelerating voltage was applied to the SEM-observed sections whenever possible in order to minimize the possibility of beam damage to the pit membranes. We believe that tearing of pit membranes from sources other than sectioning (the effects of which can easily be detected) was negligible. Our results seem comparable to the photograph of pit membranes for *Weinmannia racemosa* (Meylan & Butterfield 1978). Current literature on wood anatomy does not consider these appearances to be instances of artifact formation. In order to stress the nature of pit membrane remnants, our illustrations are at high magnifications. Our equipment does not offer maximal resolution compared to newer machinery, unfortunately. Also, the nature of SEM involves lowered retrieval of electrons from depressed areas such as perforations, and thus resolution is less than for convex structures.

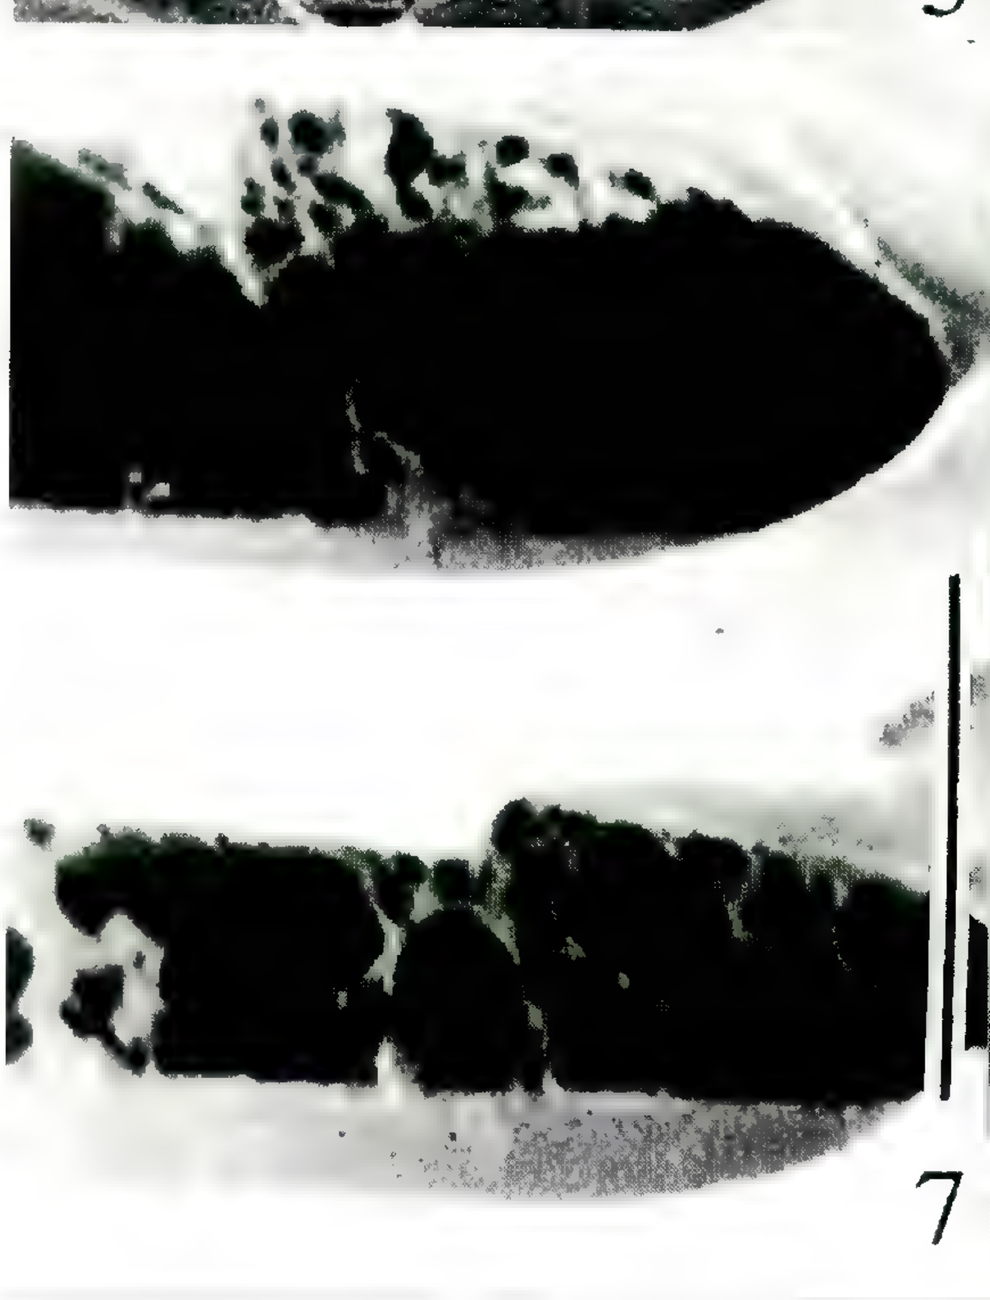
RESULTS

Perforation plates in *Illicium floridanum* (e.g., Fig. 1) are scalariform and are easily distinguished from lateral wall pitting, which consists of pits with relatively short length, separated from each other by bands of wall material appreciably wider than the bars of a perforation plate. Pit membranes of pits on lat-



FIGS. 1–4. SEM photographs of radial sections of *Illicium floridanum* vessels. Figs. 1–3. Portions of perforation plates from dried stem wood sample. **Fig. 1.** About a quarter of a perforation plate, pit membrane remnants visible in the perforations. **Fig. 2.** Perforations similar to those of Fig. 1, showing weblike pit membrane remnants. **Fig. 3.** Perforations containing strandlike pit membrane remnants; breakage of threads in the central perforations is interpreted as an artifact created by drying of wood sample or sectioning. **Fig. 4.** Pits on lateral wall of vessels, showing absence of any pores in pit membranes. Magnification scale in each figure = 5 µm.

eral walls of vessel elements were intact and devoid of any pores (Fig. 4); nearly all of the pit membranes in perforations have pores in a sheetlike membrane, or threadlike or strandlike remnants of a pit membrane (Figs. 1–3, 5–11). We have presented a photograph of an exceptional pit membrane from a perforation plate in which pit membranes that lack visible pores or holes were retained (Fig. 12); such non-porose perforation pit membranes were infrequent, present in fewer than 5% of the perforation plates we examined, with the exception of the uppermost (or lowermost) perforation in some perforation plates. One or two such terminal perforations, which may be considered transitional to lateral wall pitting, may be seen in numerous perforation plates, but no such non-porose perforations occur in the remainder of most perforation plates. Our comments, unless otherwise stated, refer to perforation plates only, and describe conditions other than the exceptional type of perforation pit membranes illustrated in Figure 12.



Pit membrane remnants are retained in perforations of the dried wood sample that was boiled in water prior to sectioning (Fig. 1–3). The durability of these membranes is attested by retention of seemingly delicate weblike membrane portions (Figs. 1, 2). Also preserved by this method are strandlike pit membrane remnants that run parallel to the long axis of the vessel element (Fig. 3).

Study of wood from living specimens of stems fixed in 50% ethanol reveals a wide range of pit membrane remnants in perforations (Figs. 5–8). Circular to oval holes in pit membranes characterize numerous perforation plates (Fig. 5). This type of pit membrane may coexist in a perforation plate with pit membranes in the form of strands (Fig. 6). Some pit membranes in the form of weblike remnants can be found (Fig. 7). Above in Figure 7 is a pit membrane fragment containing pores; this illustrates the transition between porose sheets of pit membranes and weblike pit membranes. In Figure 8, pit membrane remnants are restricted to the ends of perforations. The remnants shown contain small pores of various sizes and shapes. The perforations shown in Figure 8 are, because of restriction of pit membranes to ends of perforations, mostly clear. Perforations with small vestiges of pit membranes of this sort, but with most perforation area clear of membrane remnants, characterized about 10% of the perforation plates in this material. Also present in the liquid-preserved stems from living plants were a few perforation plates in which pit membranes were intact, like those shown in Figure 12. Such intact pit membranes are not from immature vessel elements, since they can occur at various points between pith and cambium.

Liquid-preserved roots from living cultivated plants also revealed a wide range of pit membrane conditions (Figs. 9–12). In Figure 9, portions of two perforation pit membranes are illustrated. As suggested by the irregular distribution of pores and holes, pit membranes in this perforation plate possessed some

SEM photographs of perforation portions (long axes of perforations (or pits) arranged vertically) from radial sections of wood from root of *Illicium floridanum* cultivated at the U.S. National Arboretum. **Fig. 9.** Pit membranes that have non-porose portions as well as circular to oval pores of various sizes. **Fig. 10.** Pit membranes that have some circular to oval holes; other portions of pit membranes are in the form of strands traversing the perforation. **Fig. 11.** Pit membranes that are almost entirely in the form of strands. **Fig. 12.** Portion of perforation plate illustrating intact pit membranes, lacking any visible pores. Magnification scales in each figure = 5 µm.

areas apparently devoid of pores, whereas others had small pores and others larger holes. A further stage in development of open areas within the pit membrane remnants is represented in Figure 10. The areas apparently devoid of holes in Figure 10 may result from inhibition of lysis, perhaps by adherence of some overlying substance, a possibility observed in *Ascarina* (Carlquist 1990). In Figure 11, however, minimal inhibition of lysis is evident, and almost all of the pit membrane remnants are in the form of delicate strands. Portions of an uncommon type of perforation in which hydrolysis producing pores did not occur are illustrated in Figure 12. As mentioned in the preceding paragraph, this type of perforation plate is probably not immature, because perforation plates with intact pit membranes can occur at any point between the cambium and the pith. A few perforation plates with minimal pit membrane remnants were also observed in the root material.

DISCUSSION AND CONCLUSIONS

Before examining the significance of the various manifestations of pit membrane presence in perforations, the issue of possible artifact formation must be addressed. Certainly tears due to sectioning or handling do occur, but rips in pit membranes attributable to damage can easily be identified by their contours, and are not mentioned in the above descriptions. The appearances we describe are believed to represent naturally-occurring conditions. The living stem and root portions were subjected only to dilute alcohol. The entirely intact nature of lateral wall pits of vessels in these materials serves as a control, certifying that application of this single reagent does not create artifacts. Dilute ethanol has never, to our knowledge, been claimed to create pores or holes in pit membranes.

We did observe that prolonged exposure of perforation pit membranes at high magnification and moderate to high accelerating voltage resulted in tearing. This tearing, like that due to processing, is easily identifiable, in our opinion. The pit membranes in perforations of *Illicium floridanum* seemed to resist deformation by the electron beam better than perforation pit membranes of other dicotyledons we have studied, notably *Amborella* (Carlquist & Schneider 2001b).

A source of pit membrane destruction in perforations that is difficult to estimate is the potential action of the conduction stream. One might attribute distortions like tears to pit membranes altered by the conductive stream or by formation of air embolisms.

Assuming that the appearances illustrated in the present paper are relatively free from artifacts, how can one interpret the phenomenon of pit membrane remnants in perforation plates? The distribution of dicotyledons with pit membrane remnants in perforations (Carlquist 1992a) suggests that this is a relictual feature, as though vessel elements were not definitively differentiated.

The listing given in Carlquist (1992a), if compared to recent phylogenies, such as that of Soltis et al. (2000), shows that pit membrane remnants are more common in the families of basal angiosperms, as well as in lower branches of eudicot clades and monocotyledons (Carlquist & Schneider 1998; Schneider & Carlquist 1998) on the basis of admittedly incomplete data. Many additional instances of pit membrane presence in perforations in dicotyledons have yet to be reported. However, the rarity of pit membrane remnants in the woods sampled by Meylan and Butterfield (1978) is likely indicative of the frequency of this phenomenon if a large sampling of dicotyledons were to be surveyed.

Pit membrane dissolution in perforations is presumably an easily achieved process, involving the action of enzymes. However, we do not know whether this process can be phylogenetically reversed or not. Quite conceivably, a few instances of pit membrane retention in perforations might be achieved secondarily. The occurrence of pit membranes in perforations of some *Myrothamnus* vessels might be such an instance (Carlquist 1988). However, restoration of pit membrane remnants phylogenetically seems likely to be infrequent, an occurrence only in woods with scalariform perforation plates. Once a simple perforation plate has been achieved, retention of portions of a pit membrane in the perforation plate seems unlikely, and indeed, apparently no cases of pit membrane remnants in simple perforation plates have been reported.

Degrees of pit membrane presence in perforations have been cited as indicating character state changes (Carlquist & Schneider 2002a. Five character states are designated in that paper (0 = pit membrane with no visible porosities; 1 = pit membrane with small porosities; 2 = pit membrane with less than 50% perforated; 3 = pit membrane present, but with more than 50% absent; 4 = pit membrane absent or essentially so. All stem and root wood sections of *Illicium floridanum* represented here cover the complete gamut from 0 to 4, inclusive. However, character states 0 and 4 are relatively infrequent, and could be neglected if one were constructing a data matrix for this species. The majority of perforation plates in *I. floridanum* would fall into character state 3, with character state 2 less common. We see no problem in designating the most common character state for a specimen of a particular species, even if other character states coexist with the most common manifestation. End wall angles of vessel elements and number of bars per perforation plate are features with wide ranges of expression within a single wood sample, yet they are frequently cited (often in the form of means) as indicators of degree of phylogenetic specialization.

RICHARD SPELLENBERG. 2003. **Sonoran Desert Wildflowers.** (ISBN 0-7627-1136-1, pbk.). The Globe Pequot Press, 246 Goose Lane, PO Box 480, Guilford, CT 06437, U.S.A. (Orders: 800 826-8911, fax 800-820-2329). $24.95 pbk., 246 pp., numerous color photos, 7 b/w figures, 1 map, 1 graph, 7" × 9".

From the back cover: *Sonoran Wildflowers* is the ultimate field guide to wildflowers of North America's most biologically diverse desert, which straddles the Gulf of California between the Baja Peninsula and northwestern Sonora and stretches north into California and Arizona. Packed with vivid color photos and informative text, this valuable reference will help you identify and appreciate the varied flora of this vast region's six different climates." The author's photographs are exceptionally crisp and vibrant. Botanists and wildflower enthusiasts alike cannot go wrong with having this book in their library.—*Barney Lipscomb, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX 76102-4060, U.S.A., barney@brit.org.*

ELIZABETH A. (BERNDT) GEORGE, watercolour paintings and illustrations by MARGARET PIERONI. 2002. **Verticordia: The Turner of Hearts.** (ISBN 1-876268-46-8, hbk.). University of Western Australia Press (www.uwapress.uwa.edu.au), Crawley, Western Australia 6009 in association with Australian Biological Resources Study, GPO Box 787, Canberra, Australian Capital Territory 2601. (Orders: International Specialized Book Services, 5824 NW Hassalo St., Portland, OR 97213-3644, U.S.A.; 503-287-3093, fax 503-280-8832, www.isbs.com, email: info@isbs.com). $84.95 hbk., 422 pp., 102 plates of watercolor paintings with line drawings, maps, 8 1/4" × 11 14".

From the back cover: "*Verticordia: The Turner of Hearts* brings together for the first time available information on all the described taxa of *Verticordia* (101 species, 13 subspecies and 30 varieties) providing a comprehensive, user-friendly guide to their identification and cultivation." *Verticordia* is a member of the Myrtaceae family. Each species comes with a description followed by information on the distribution, habitat, flowering period, distinguishing characteristics, other names used (synonyms), cultivation, and conservation status. A key to infrageneric taxa and species is provided.—*Barney Lipscomb, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX 76102-4060, U.S.A., barney@brit.org.*

COMPARISON OF THE MORPHOLOGY, FLOWERING PHENOLOGY, AND LIFE CYCLE TYPE IN PLANTS OF *GRINDELIA LANCEOLATA* (ASTERACEAE) FROM CEDAR GLADES IN MIDDLE TENNESSEE AND NORTHERN ALABAMA: A COMMON GARDEN STUDY

ABSTRACT

The life cycle type of *Grindelia lanceolata* Nutt. has been described as biennial, short-lived monocarpic perennial, and (polycarpic) perennial in the taxonomic literature. Plants of this species in middle Tennessee cedar glades clearly are monocarpic. However, field observations suggested that those from glades in northern Alabama are at least dicarpic, and further that they differ morphologically and flower later than those in Tennessee glades. The purpose of this study was to determine if differences in morphology, flowering phenology, and/or life cycle type of Tennessee and Alabama plants are retained when grown from seeds in a "common garden" - i.e., in a nonheated greenhouse in Lexington, Kentucky. Morphological differences (all statistically significant) between *G. lanceolata* plants from Tennessee and Alabama were measure in the following: (1) size of both rosette and stem leaves; (2) number of secondary basal stems; (3) height of primary stem; (4) number of capitula per plant; (5) number of ray and of disk flowers per capitulum; (6) diameter of capitulum; and (7) length of ray flower corolla . Tennessee plants began flowering about 1 month earlier than Alabama plants, and none of them produced basal rosettes after they flowered once (in their 2nd year), confirming that they are strictly monocarpic. Alabama plants also flowered first in their 2nd year; however, 66% of them have produced basal rosettes (which bolted and flowered) for five consecutive growing seasons, confirming that they are polycarpic. Also, individual Tennessee plants potentially can produce twice as many seeds as individual Alabama plants during a single flowering/fruiting period. These results strongly suggest genetic differences exist in vegetative and floral morphology, flowering phenology, and life cycle type between Tennessee and Alabama plants of *G. lanceolata*. We speculate that these differences could be associated with different ancestral geographic origins: Tennessee plants from a monocarpic race in the Ozarks and Alabama plants from a perennial race in the Southwest.

RESUMEN

El tipo de ciclo de vida de *Grindelia lanceolata* Nutt. ha sido descrito, en la literature taxonómica, como bianual, como perenne monocárpico de vida corta y como perenne (policárpico). Las plantas

[1]Christopher A. Adams, corresponding author: Telephone (859) 257-3996; FAX (859) 257-1717; email: caadam0@uky.edu

SIDA 20(3): 1059–1071. 2003

de esta especie presentes en claros calcáreos del área central de Tennessee son claramente monocárpicas. Sin embargo, observaciones de campo sugieren que aquellas de la zona norte de Alabama son, al menos, dicárpicas; y mas allá, que difieren morfológicamente y que florecen más tarde que aquellas de los claros calcáreos de Tennesssee. El propósito de este estudio fue determinar si las diferencias en morfología, fenología floral y/o tipo de ciclo de vida de plantas de Tennessee y Alabama se mantienen cuando las plantas crecen a partir se semillas en un "jardin comun" - i.e., en un vivero sin calefacción en Lexington, Kentucky. Las diferencias morfológicas (todas estadísticamente significativas) entre plantas de *G. lanceolata* de Tennessee y de Alabama incluyen: (1) el tamaño de ambas clases de hojas, de roseta y de tallos; (2) número de tallos basales secundarios; (3) altura del tallo principal; (4) número de capítulos por planta; (5) número de flores radiales y de disco por capítulo; (6) diámetro del capítulo; y (7) longitud de la corolla de las flores radiales. Las plantas de Tennessee comenzaron a florecer aproximadamente 1 mes más temprano que las plantas de Alabama y ninguna de ellas produjo rosetas basales después de haber florecido una vez (en su 2do año), confirmando que son monocárpicas estrictas. Las plantas de Alabama también florecieron en su 2do año; sin embargo, 66% de ellas siguió produciendo rosetas basales (que desarrollaron tallo y florecieron) por cinco períodos de crecimiento, confirmando que son policárpicas. Además, cada individuo de Tennessee puede producir potencialmente el doble se semillas que los individuos de Alabama durante cada período de floración/fructificación. Los resultados sugieren claramente que hay diferencias genéticas en la morfología vegetativa y floral, la fenología floral, y los tipos de ciclo de vida entre plantas de *G. lanceolata* de Tennessee y de Alabama. Especulamos que estas diferencias pueden deberse a que estos dos grupos tengan diferentes orígenes geográficos: las plantas de Tennessee, de una raza monocárpica en los Ozarks; y las plantas de Alabama, de razas perennes del sudoeste.

INTRODUCTION

Grindelia lanceolata Nutt. (Asteraceae) is an herbaceous species that grows in open habitats on shallow soils underlain by limestone (Steyermark 1934, 1937; Baskin and Baskin 1979). Its geographical range extends from the Ozarks of Missouri and southeastern Kansas, south through eastern Oklahoma and northern and western Arkansas, and into northeastern and central Texas (Steyermark 1934, 1999; Correll and Johnston 1970; GPFA 1986; Smith 1988; Nesom 1990). Nesom (1990) also reports the species from the Monterrey area in Nuevo Leon, Mexico. Disjunct populations occur in the Central Basin of Tennessee (Chester et al. 1997) and in northern Alabama (Small 1933; Harper 1944), where they are associated closely with open cedar glades (Baskin & Baskin 1979, 1996; Baskin et al. 1995). *Grindelia lanceolata* has been reported from Louisiana (Rydberg 1932; Small 1933); however, Gandhi and Thomas (1989) do not list the species in their recent treatment of the Asteraceae of Louisiana. The species also has been reported from a single county in southeastern Ohio (Jones 1943; Fisher 1988), where, apparently, it has been introduced (Porter 1956).

In his taxonomic treatment of Texas species of *Grindelia*, Nesom (1990) recognized three varieties of *G. lanceolata*: *lanceolata*, *texana* (Scheele) Shinners, and *greenei* (Steyermark) Nesom, the latter known only from Mexico. However, Correll and Johnston (1970) did not recognize any separate taxonomic entities and thus included only *G. lanceolata* in their treatment. Julian A. Steyermark listed two forms of *G. lanceolata* in his Flora of Missouri (1999): *lanceolata* and

latifolia Steyerm., the latter known from only one county in Missouri. Small (1933), Fernald (1950), Gleason (1963), GPFA (1986), Gleason and Cronquist (1991), and Chester et al. (1997) do not recognize any intraspecific taxa in *G. lanceolata*.

With regard to life cycle type, *G. lanceolata* has been reported to be biennial (Rydberg 1932), short-lived monocarpic perennial (Baskin & Baskin 1979; GPFA 1986; Gleason & Cronquist 1991), and (presumably polycarpic) perennial (Small 1933; Correll and Johnston 1970; Enquist 1987; Nesom 1990). In their study on the autecology and population biology of *G. lanceolata* in the limestone cedar glades of the Central Basin of Tennessee, Baskin and Baskin (1979) found that plants were short-lived monocarpic perennials (i.e., plants lived for a few years before they bolted and flowered once, and then died). The youngest plants to flower in the Baskins' study were in their third growing season (2+ years old). Other plants in the study flowered in their fourth or fifth year; all plants died after flowering once (i.e., monocarpic).

However, during field studies in the limestone cedar glades in northern Alabama, Baskin and Baskin (pers. obs.) noticed that Alabama plants of *G. lanceolata* differed in morphology, flowering time, and life cycle type. In contrast to plants in Tennessee, rosettes were present on those with dead flowering stalks in Alabama, suggesting that this species is at least dicarpic in the cedar glades of northern Alabama. The purpose of this study was to determine if there are distinct measurable or observable differences in vegetative morphology, floral morphology, flowering phenology, and/or life cycle type between *G. lanceolata* plants from Tennessee and Alabama cedar glades. To determine if differences in morphology and life cycle type are genetically—or environmentally—based, both Tennessee and Alabama plants were grown from seed in a common environment, i.e., a common garden experiment.

MATERIALS AND METHODS

Growth Conditions

All plants used in this study were grown from seeds in a nonheated greenhouse in Lexington, KY. Seeds were collected in autumn 1996 from *G. lanceolata* populations growing in cedar glades in Tennessee and Alabama and sown (separately) on soil in metal flats. The greenhouse soil mix was a 3:1 (v/v) mixture of limestone-derived topsoil and river sand. Following germination, juveniles were transplanted to 15-cm-diameter plastic pots in spring 1997 and assigned a number. Morphological and life cycle features of 103 Alabama plants and of 88 Tennessee plants were monitored in this study; plants of both groups were numbered consecutively.

Temperatures in the nonheated greenhouse were recorded continuously with an electric thermograph for the duration of the five-year study period. From these recordings, mean daily maximum and minimum temperatures for

TABLE 1. Five-year mean monthly maximum (± SE) and minimum (± SE) temperatures (°C) to which *Grindelia lanceolata* plants were exposed during the study.

Month	Maximum	Minimum
January	6.95 ± 1.4	1.71 ± 0.38
February	10.95 ± 0.88	4.00 ± 0.72
March	14.48 ± 1.40	5.65 ± 1.10
April	21.92 ± 1.30	11.81 ± 0.64
May	28.6 ± 0.77	18.22 ± 0.79
June	30.62 ± 0.46	20.9 ± 0.49
July	32.13 ± 1.20	23.15 ± 0.85
August	31.68 ± 0.92	22.05 ± 0.71
September	28.18 ± 0.95	17.75 ± 0.99
October	20.05 ± 0.35	12.6 ± 0.68
November	15.6 ± 1.10	8.23 ± 1.00
December	8.5 ± 1.40	3.03 ± 0.60

each month for each of the five years were determined. These temperatures then were used to calculate mean maximum (± SE) and minimum (±SE) monthly temperatures (°C) for the study (Table 1). Average daily photosynthetic photon irradiance at plant level in the nonheated greenhouse, measured with a LI-COR model LI-1000 data logger and three LI-190-SA quantum sensors, ranged from 6 mol m^{-2} d^{-1} on overcast days to 25 mol m^{-2} d^{-1} on clear days during the growing season (March to October) (Snyder et al. 1994).

Vegetative and Floral Morphology

To determine if there are differences in vegetative morphology, various leaf characters were compared between the two groups of plants. Length, width, oven-dry mass, and specific leaf area were determined for leaves collected from the rosette and from the lower-, middle-, and upper (just below the terminal capitulum) portions of the main stem. One leaf each from these four regions of the shoot was removed and measured/weighed for every plant in the study. Leaf length and width were measured to the nearest mm using a standard metric ruler. The width measurement was taken at the widest part of the leaf. Leaves were dried in an oven at 70°C for 24 hours, and their dry mass determined with an analytical balance. Average values for each leaf character were calculated for all plants in the study. Leaf prints were made using Diazo-type paper for ammonia developing, and leaf area (one side of leaf) was determined by weight of paper/area print relationships. Specific leaf area (SLA) was calculated using the following equation: $SLA = A_{leaf}/W_{leaf}$ where A_{leaf} is leaf area (one side only) and W_{leaf} is leaf dry weight. SLA was determined for one leaf from each of the four shoot levels for each plant in the study, and then average values were calculated for leaves of each position. In addition, number of secondary basal stems

and height of each plant were determined and averages calculated. All means were compared by t-tests (P=0.05).

Number of capitula for the main stem and for all secondary stems were counted and averages calculated for each plant in the study. Floral measurements were made on 15 Tennessee plants and on 15 Alabama plants selected randomly using a random-numbers table. Number of ray and disk flowers, length and width of ray flower corolla, and diameter were measured, to the nearest mm, for the terminal capitulum of the main stem of each of the 30 plants. The terminal capitulum is always the first to flower on a plant. Capitulum diameter and corolla length and width were measured using a standard metric ruler and means calculated. All means were compared by t-tests (P=0.05).

Flowering Phenology

The terminal capitula of the main stems were monitored for flowering. The flowering period in this study extended from the beginning of flowering (indicated by the first anther of the first disk flower to shed pollen; ray flowers are pistillate) in the first plant and ended with the beginning of flowering in the last plant. Beginning of pollen shed was determined by brushing a finger across the anthers and observing if clumps of the bright yellow pollen adhered to it.

Seed Production Potential

To assess the reproductive effort of *G. lanceolata*, potential number of seeds per individual plant was calculated. Potential number of seeds per individual for Alabama and for Tennessee plants was calculated as follows: Potential number of seeds produced per plant = (Avg. no. capitula per main stem x Avg. no. ray flowers per capitulum) + (Avg. no. capitula per main stem x Avg. no. disk flowers per capitulum) + (Avg. no. capitula per secondary stem x Avg. no. secondary stems x Avg. no. ray flowers per capitulum) + (Avg. no. capitula per secondary stem x Avg. no. secondary stems x Avg. no. disk flowers per capitulum).

RESULTS

Vegetative and Floral Morphology

Length, width, dry weight, and SLA of leaves from the rosette, and from the lower-, middle-, and upper portions of the main stem, differed significantly between Tennessee and Alabama plants of *G. lanceolata* (Table 2). Only rosette dry weight and length of leaves on the lower portion of the stem were nonsignificant. In general, plants from Alabama had longer, wider, and heavier leaves, a higher SLA, and were taller than Tennessee plants. However, Tennessee plants produced significantly more secondary stems than Alabama plants (Table 2).

Tennessee plants produced significantly more capitula per plant on both main stems and secondary, basal stems than did Alabama plants (Table 3). Average number of capitula per main stem and per secondary stem was significantly higher for Tennessee plants. Alabama plants produced larger capitula

(i.e., greater diameter) and more ray flowers per capitulum than did Tennessee plants. Number of disk flowers, however, did not differ significantly between the two groups. Ray flowers from Alabama plants had longer petals than Tennessee plants, but there was no difference in petal width between the two groups.

Flowering Phenology

All plants from both groups bolted and flowered in their second year. Flowering in Tennessee plants began on 1 July 1998, and all terminal flowers of main stems had flowered by 5 August 1998 (Fig. 1). In contrast, flowering in Alabama plants began and ended on 26 July and 7 September, respectively. For both groups, capitula elsewhere on the main stem and on secondary stems continued to

TABLE 3. Comparison of number of capitula and of ray and disk flowers produced by *Grindelia lanceolata* plants from Tennessee and Alabama. All values are expressed as means (± SE) except for total number of capitula produced by all plants. An asterisk indicates means of each character are significantly different (t test, P = 0.05), whereas NS indicates that they are not significantly different at this level.

Character	Tennessee	Signif. Level	Alabama
Total No. Capitula Produced

No. Disk Flowers	203 ± 34	NS	252 ± 71
Capitulum Diameter (cm)	4.4 ± 0.2	*	5.7 ± 0.5

flower 1–2 weeks following the beginning of anthesis of the last terminal main stem capitulum.

After completion of flowering, all Tennessee plants (n=88) died; not a single one produced a new basal rosette. However, many Alabama plants continued to produce new rosettes and to bolt and flower over the course of the five-year study period (Figs. 1, 2). One-hundred and three Alabama plants bolted and flowered in 1998, 78 in 1999, 74 in 2000, 73 in 2001, and 68 in 2002 (Fig. 2). Flowering period duration was 43 days in 1998, 48 in 1999, 43 in 2000, 39 in 2001, and 44 in 2002 (Fig. 1). Length of flowering period in 1998 was 36 days for Tennessee plants (Fig. 1). Flowering (both terminal and all other capitula) for both groups had been completed by mid-September.

Seed Production Potential

An individual Tennessee plant had the potential to produce an average of 3,128 seeds, while a single Alabama plant had the potential to produce only 1,568 seeds.

DISCUSSION

Observations by Baskin and Baskin that Alabama *G. lanceolata* plants appeared to be distinct in morphology, flowering time, and life cycle type from those in Tennessee were supported by the results of this study. Alabama plants are taller and have larger leaves than Tennessee plants. One of the more striking differences between the two groups is the number of secondary basal stems. Tennessee plants produce more than two times as many secondary basal stems as do Alabama plants, giving them a suffrutescent-like appearance. Indeed, Tennessee

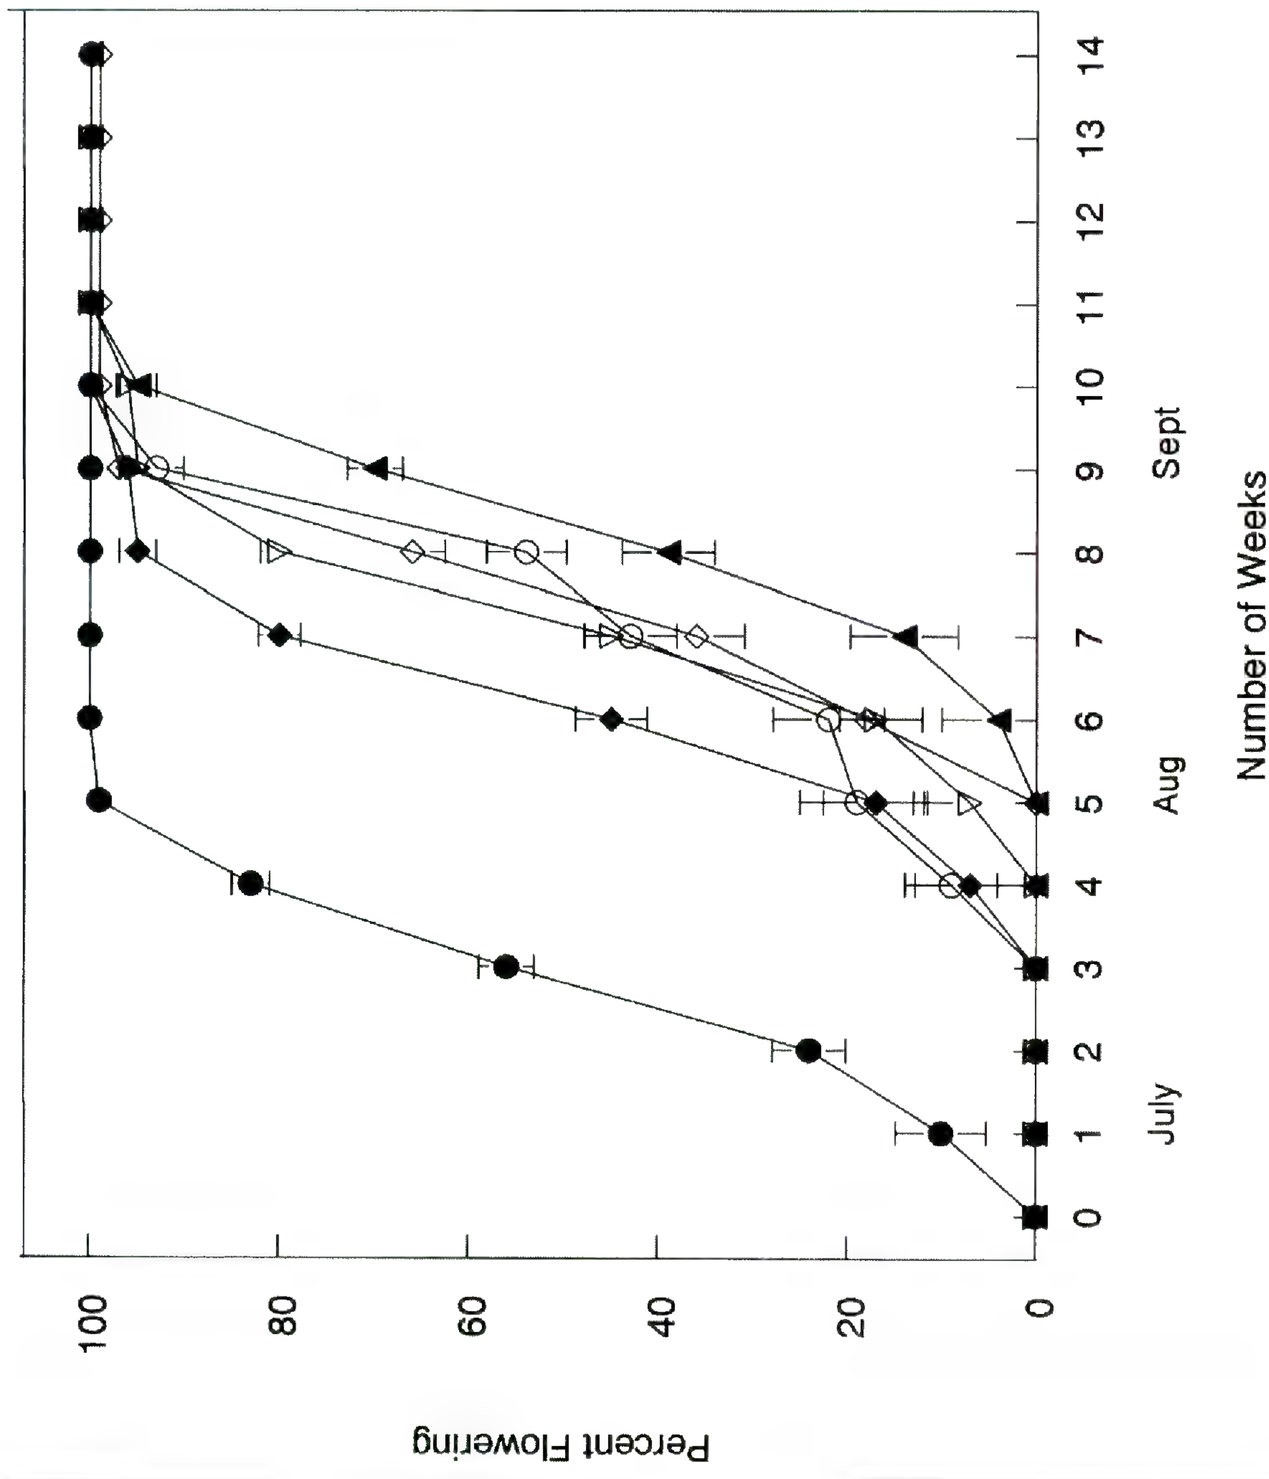

Fig. 1. Flowering phenology for 88 Tennessee *Grindelia lanceolata* plants in 1998 (●) and for 103 *Grindelia lanceolata* Alabama plants in 1998 (◆), 1999 (◇), 2000 ( ), 2001 (▲), and 2002 (○).

and Alabama plants can be distinguished easily on the basis of height and branching pattern.

Average diameter of the terminal capitulum of Alabama plants is greater, by more than 1 cm, than that of Tennessee plants. Compared to Tennessee plants, terminal capitula of Alabama plants produce significantly more ray flowers and longer ray petals. On the other hand, Tennessee plants produce twice as many capitula per secondary stem and nearly twice as many (1.85:1) per main stem as do Alabama plants.

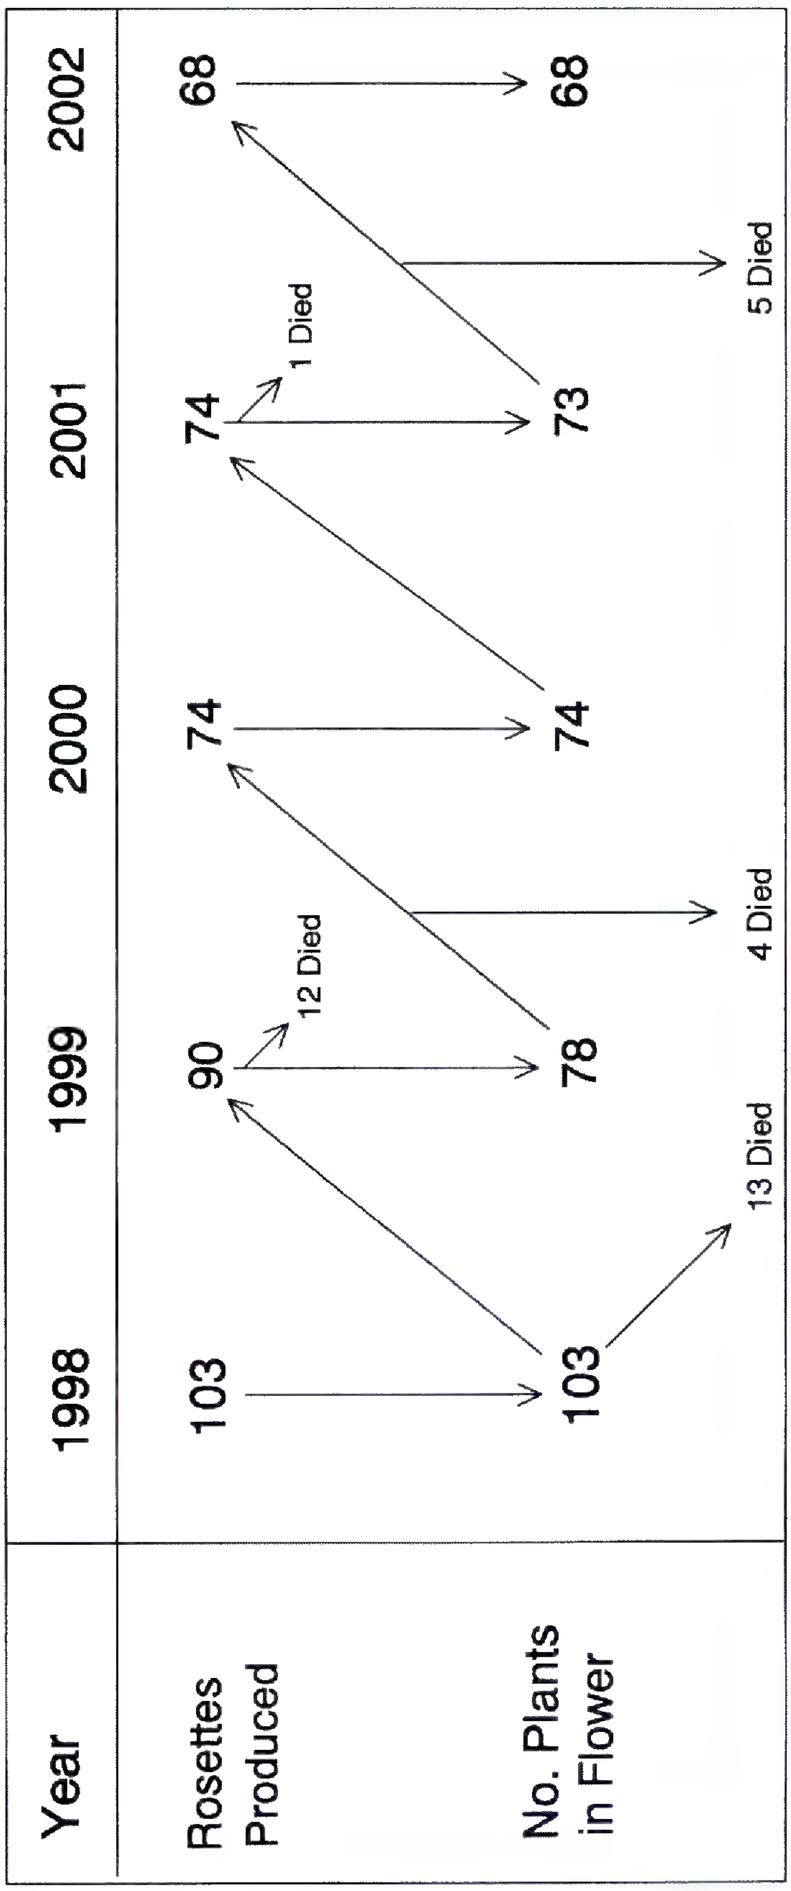

FIG. 2. Fate of 103 Alabama *Grindelia lanceolata* plants grown from seed in a non-heated greenhouse. All plants that produced rosettes in 1998 were in their second year of growth.

Number of seeds per plant produced during a single reproductive event was considerably higher in the monocarpic perennial ("biennial") plants (Tennessee) than in the polycarpic plants (Alabama). Salisbury (1942) reported that biennials in Great Britain produced an average of more than four times as many seeds as did polycarpic perennials. Duffy et al. (1999) predicted that monocarpic species should maximize the number of meristems (i.e., branches) devoted to reproduction, which would allocate as many reserves as possible to reproductive effort since there is only one reproductive event. Conversely, they predicted that polycarpic perennials should maximize the number of growth meristems (but not reproductive ones) since there is a fitness premium on longevity and competitive ability. Tennessee plants produced 2.2 times as many secondary basal stems, all of which flowered, as did Alabama plants. As a result, Tennessee plants produced, on average, significantly more capitula and had the potential to produce almost twice as many seeds as did Alabama plants. Thus, Tennessee plants obviously devoted more energy to reproductive meristems than did Alabama plants, which devoted more energy to growth in height and perennation. Whereas all Tennessee plants died after flowering once, the majority of Alabama plants continued to flower each year for several years. By producing fewer flowers, Alabama plants have reserve energy for production of new rosettes (i.e., perennation), which also should be considered growth meristems. Thus, there is a tradeoff between number of seeds produced per reproductive event and lifespan of an individual.

A very interesting difference between Tennessee and Alabama plants is life cycle type. In the nonheated greenhouse, both Tennessee and Alabama plants bolted and flowered in their second year. However, whereas all 88 Tennessee plants died after they reproduced once, only 13 of 103 Alabama plants did so. Thus, 100% of the Tennessee plants, but only 13% of the Alabama plants, behaved as biennials. Another 12% of the Alabama plants were dicarpic, 12% were tricarpic, and 1% tetracarpic, dying after their third, fourth, and fifth years, respectively. Sixty-six percent of the original 103 Alabama plants have flowered in their second, third, fourth, fifth, and sixth years, and it is expected that most of them could survive and flower for the next several growing seasons.

Apparently, differences in morphology, flowering time, and life cycle type between Tennessee and Alabama plants are genetically-based, since they were maintained in plants grown from seeds in a common environment. However, the advantage, if any, for *G. lanceolata* behaving as a short-lived monocarpic perennial in Tennessee glades, and of it behaving as a polycarpic perennial in the cedar glades in northern Alabama, is not known. Floristically and vegetationally, cedar glades of northern Alabama are very similar to those in central Tennessee (Baskin et al. 1995; Baskin & Baskin 1999, in press). Further, soils in both areas are limestone-derived, and climatic differences are minimal;

both areas are within Köppen's Cfa climate type (i.e., mild temperate rainy climate without a distinct dry season, and with a hot summer) (Ackerman 1941). Soil moisture and microclimate in cedar glades cause stress in plants in Tennessee glades (Baskin & Baskin 1999), and one would expect the same conditions in glades in Alabama. Thus, there are no apparent physical or biotic differences between Tennessee and Alabama glades that would seem to favor a monocarpic life cycle in one area and polycarpic life cycle in the other. A reciprocal transplant study would help to determine if, in fact, plants are subjected to different sets of selective factors on life history in the two areas, one favoring monocarpy and the other polycarpy.

In terms of r and K life history strategy (e.g., Pianka 1970), data collected in this study indicate that Tennessee plants are more r-selected than are Alabama plants, which are somewhat further along the r-K continuum to being K-selected. Thus, compared to Alabama plants, Tennessee plants are monocarpic, short-lived, smaller in stature, and much more productive in terms of numbers of seeds per reproductive event.

Could differences in geographic origin of Tennessee and Alabama plants account for the differences between them? Plants in Alabama glades could be disjunct from ancestor populations in southwestern United States, specifically in Texas. Texas floras (Correll & Johnston 1970; Enquist 1987; Nesom 1990) consistently describe the species as a (presumably polycarpic) perennial. This genetic race may have spread from Texas into Alabama, and the two groups became separated through geologic time. On the other hand, it seems likely that plants in the middle Tennessee cedar glades are disjunct from short-lived monocarpic or biennial races (Rydberg 1932; Wetter 1986; Gleason & Cronquist 1991) in the Ozark Region. Several other species, e.g., *Evolvulus nuttallianus* R. and S., *Oenothera macrocarpa* Nutt. subsp. *macrocarpa*, *Onosmodium molle* Michx. var. *subsetosum* (Mack. & Bush) Cronquist, and *Solidago gattingeri* Chapm. are disjunct between the limestone glades of Missouri and those in Tennessee, and none of these occurs in Alabama glades (Baskin & Baskin 1986; Bridges & Orzell 1986; Baskin et al. 1995; Baskin & Baskin in press).

ABSTRACT

The cultivated grain and the weedy *Amaranthus* L. species (section *Amaranthus*) originated in the Americas. The Spaniards conquered the New World in the 16th century. Consequently, the North American species of *Amaranthus* could not have been introduced in Europe before this date. However, the name of the amaranth existed long before its association with plants in the genus described by Linnaeus. Several everlasting plants were named "amaranth" by the ancient Greeks and Romans, and in the medieval times. Among these, *Helychrisum* spp. and *Celosia argentea* L. are the most common. The name "Amaranthus" has had multiple meanings and ramifications through time: botanical, ethnobotanical, religious, literary and philosophical. This paper explores this history of meanings of the name "Amaranthus."

RESUMEN

Las especies cultivadas como pseudocereales y las malas hierbas de *Amaranthus* L. (sección *Amaranthus*) tuvieron su origen en las Américas. Los españoles conquistaron el Nuevo Mundo en el siglo dieciséis. Consecuentemente, las especies norteamericanas de *Amaranthus* no se pudieron haber introducido en Europa antes de esta fecha. Sin embargo, el nombre del amarantho existió mucho antes de su asociación con plantas del género descrito por Linneo. Varias plantas fueron denominadas "amaranth" por los griegos y romanos antiguos, así como en los tiempos medievales. Entre éstos, *Helychrisum* spp. y *Celosia argentea* L. fueron algunos de los más comunes. El nombre "Amaranthus" ha tenido múltiples significados y ramificaciones a través del tiempo: botánicos, etnobotánicos, religiosos, literarios y filosóficos. Este artículo explora esta historia de significados del nombre "Amaranthus."

INTRODUCTION

The genus *Amaranthus* of Linnaeus includes species that originated in the Americas, Africa and Eurasia. The association between these plants and the name *Amaranthus* is relatively recent. American cultivated grain amaranths (*Amaranthus caudatus* L., *A. hypochondriacus* L. and *A. cruentus* L.) and their wild relatives (*A. hybridus* L. and *A. powellii S. Wats.*) were introduced in Europe in the 16th century, after Spaniards conquered the New World (Sauer 1950, 1967). Other *Amaranthus* species, such as *A. tricolor* L. from Asia, and *A. blitum* L. from Eurasia were also associated with this name in or after the 16th century (Gerard 1633; Thellung 1914). Yet, the name of the amaranth had been used by the ancient Greeks and Romans almost two millennia before. Therefore, the

question is: what was the ancient amaranth and how did the meaning of this name changed in time? An investigation into the history of the name "Amaranthus" revealed multiple meanings and ramifications through time: botanical, ethnobotanical, religious, literary and philosophical. This paper is an attempt to tell the story of the name of the amaranth.

Etymology and Nomenclature

Amaranthus L. Sp. pl.:989. 1753. = *Amaranthus* Adans. Fam. Pl. II, 269, 516. 1763.

The ancient Greek name used by Dioscorides (4:57, Gunther 1959), ἀμάραυτοζ (amárantos) came from the adjective ἀμάραυτοζ, unfading (alpha privative, not + maraíno, fading), alluding to the everlasting nature of the flowers and inflorescences. In ancient Greece, *Amaryntus* was a village in Euboea, where *Amaryntium*, the temple of Artemis *Amaryntia* was situated (Strabo, The Geography 10:10, 12; 1959–1961). However, these names probably derived from the same etymology. The Latin form adopted by Pliny the Elder (Natural History 21:41, 1951) was "amarantus." Instances when the word was not associated with a plant can be found in the Greek New Testament, 1 Peter 5:4, "*ton amarantinon tes doxes stephanon*" ("the unfading crown of glory") and 1 Peter 1:4, "*kai amaranton*" ("will not fade away") (see Rienecker 1980). Lucianus Samosatenis described a fresco painting of a flowery meadow as "eternal spring and unfading (*amarantos*)" (The Hall 9, 1949).

Later, Tournefort (1694) stated that the name came from the alpha privative (α)—"not," and the words "*marceo*" (the Latin equivalent of "maraino")—"to fade," meaning "never fading" and "*anthos*" (ἀνθοζ)—"flower." As Ray (1686–1688) observed, the second analogy was forced: "*Amarantus male cum 'th' scribitur Amaranthus.*" Thellung (1914) also noted that if the word "*anthos*" had been incorporated in the etymology, the name should have been "*Amarananthus*" and not "*Amaranthus.*" Both *Amarantus* and *Amaranthus* were used in the 16th and 17th century (reviewed by Sprague 1928). However, Linnaeus knew both forms and deliberately rejected the classical spelling *Amarantus* in favor of *Amaranthus* (Sprague 1928). The retention of the original *Amaranthus* spelling should be followed even if it is less desirable philologically (Saint Louis Code, article 60.1).

The Huauhtli.—Amaranths were called *huauhtli* by the Aztecs (see Wimmer 2003). We wanted to see if "unfading" served as an etymological root for *huauhtli* in the same way it did for *Amaranthus*. "*Huauh-*" in the Nahuatl of the 16th century was an independent nominal radical, connected with no other root. "*Huâqui*," to dry, would give the name "*huâctli*," a dried out thing, word which unfortunately could not be retraced to any old uto-aztecan roots (Wimmer, pers. com.). The history and ethnobotany of *huauhtli* are fascinating since its relationship with man goes back more than 6000 years (Sauer 1950; Cole 1979). The

uses of *huauhtli*, and its social, religious and economic significance during the Aztec Empire, are well known today (e.g. Sauer 1950, 1967; Cole 1979; Early 1992). *Huauhtli* played an important role in many Aztec religious ceremonies. Huge idols were molded from the dough prepared from *huauhtli* flour and popped grains, which were then mixed with honey and sometimes with blood. The idols were dedicated to several gods, among which the war god Huitzilopochtli was the most prominent. The rituals involved human sacrifices and the Spanish conquistadors tried to suppress the "pagan" culture by prohibiting the cultivation of the *huauhtli* (Sauer 1950; Cole 1979). Crop fields were burned and Aztec people killed if they were found to possess the plant or its grains. Despite their efforts, the conquistadors could not eradicate *huauhtli* and the plants endured the time, awaiting their new name.

The Amaranth: Several Everlasting Plants.—The name of the amaranth preceded the introduction of *huauhtli* in Europe in the 16th century. It also preceded the introduction of *A. tricolor* L. from Asia in the 16th century. Another Euroasian species, *Amaranthus blitum* L., was known in ancient Greece as "*blite*" (Theophrastus Book 1. 14:2, Book 7. 1:2–3, 3:2, 3:4, 14:2, 1916; Dioscorides 2:143, see Gunther 1959), and it became associated with the name *Amaranthus* only in the 17th century (Thellung 1914). The ancient amaranth was an everlasting plant used by the ancient Greeks for garlands of deity statues and in death rituals. Dioscorides (4:57, Gunther 1959) mentions ἀμάραντοζ (amarantos) as a synonym for *elichruson* (*Helychrisum* spp., most probably *H. arenarium* (L.) Moench), an everlasting plant with yellow flowers (phyllaries) used by the Greeks "to crown idols." "The hair (the inflorescences) being drank with wine doth help Dysuries, & ye bitings of serpents, & Sciaticas, & ruptures, & it moves ye menstrua, & consumes the clots of blood which are in ye bladder or ye belly, being drank with mustum" (Dioscorides 4: 57, Gunther 1959). The yellow amaranth mentioned several times in Vatsyayana's Kama Sutra, may also be *Helychrisum* (Burton 1963).

During the Roman Empire, Pliny the Elder described "Amarantus" as "*autem spica purpurea verius quam flos aliquis*" (Natural History 21:41, 1951). The description indicates that the amaranth at that moment was probably *Celosia argentea* L., an Amaranthaceae from Asia and Africa that resembles *Amaranthus* spp. in many respects. Indeed, the author distinguished the amaranth from *Helichrysum* (21:168), and the latter retained all the characteristics and uses previously mentioned by Theophrastus and Dioscorides. However, it should be noted that the name of the amaranth was again associated with an everlasting plant. The amaranth referred to by Ovid (4:435, 1931), Tibullus Albius (3.4.33, 1962), Plutarch (Questiones convivales 3.13.648A, 1949) and Columella (10:175, 1941) was also *C. argentea*. In the 15th and 16th century, the name *Amaranthus* (or *Amarantus*) was applied equally to *Helychrisum* spp., to the

amaranths introduced from the New World, to *C. argentea*, and even to *Gomphrena globosa* L., another Asian Amaranthaceae. For example, in 1542 Fuchs described and illustrated two amaranths ("*flos-amoris*"): "*Duplex est Amarantus: unus luteus* (*Amarantus luteus* = "Helychrison" = *Helychrisum arenarium*) [...], *alter purpureus*" (*Amarantus purpureus* = *C. argentea*) (De Historia Stirpium 98–101, 1542). Matthioli's illustration of the amaranth from 1563 (in Krutch: 128, 1976; Fig. 1) is also probably *C. argentea*. Henry Fletcher, a painter active in London around 1730, in a reproduction of a Pieter Casteels' painting, identified a plant of *C. argentea* as "yellow Amaranthus" (see Segal 1990). "Floramore" or "Flour Amore" was equally a popular name for *Amaranthus tricolor*, for *Celosia argentea* (= *Amaranthus purpureus*, Gerard 1633; Henry 1829; Fisher 1998) and for the real amaranths ("Amaranthus Pannicula Sparsa," Gerard 1633; see also Meyer et al. 1999). The confusion is understandable. *Amaranthus* and *Celosia* are similar in many respects, and North America was thought initially by Christopher Columbus to be a part of Asia. It is difficult to ascertain who was the first botanist to distinguish the two genera and who was the first to associate the name with today's amaranths. The distinctive in florescence of *A. caudatus* was described by Parkinson (1640. 753) and Ray (1686–1688, 1: 202). Although Ray did not mention *Celosia*, his "*Amarantus*" was classified accurately in the group with "*herbae florae imperfecto sexu carentes sunt vel femine*" (Methodus Plantarum, Tab. 5, 1684) (*Celosia* has bisexual flowers). It was Linnaeus who legitimized the differences between the two genera (*Celosia* Sp. Pl. 205. 1753; for *Amaranthus* see above).

The Amaranth: A Magical Plant.—Theophrastus, who preceded Dioscorides by approximately 300 years, did not mention *Amaranthus*. He wrote about the "magical properties" of the gold-flower (*Helychrisum* spp.), which was capable of bringing fame and wealth to those who wreathed themselves with the flowers sprinkled with an "unguent from a vessel of unfired gold" (Book 9, 19:2–4, 1916). However, Theophrastus was skeptical about "such tales ... (which) proceed from men who desire to glorify their own crafts." Athenaeus of Naucratis cited Theophrastus, but in a credulous tone, affirming that the plant really is magical and capable of bringing fame and fortune (15:680, 1955–1961). Medieval herbalists followed Dioscorides' synonymy and transferred the virtues of the "helichruson" to the amaranth. Joannes Ammonius Agricola called amaranth "*flos honoris*" (Medicinae Herbariae:35, 1539) because the flower was capable of bringing honor. Since "its flowers (are) dedicated to the gods and rarely to living men," dreaming garlands of amaranth (was) a bad sign for sick people but a good one "for everyone, especially for people involved in lawsuits" (Artemidorus Daldianus 1:77, 1975). English colonists sailing for America wore magical amulets containing amaranth seeds to protect them (Cole 1979). Later, in the 19th century Americans believed that the amaranth could attract light-

FIG. 1. "Amaranthus" from Matthioli 1563, probably *Celosia argentea* L.

ning (Cole 1979). Today, hundreds of Web pages and magic books recommend amaranth as the flower of "protection, healing and invisibility" (e.g. Cunningham 1993a, b). Wearing a wreath of amaranth speeds healing (even of a broken heart) and grants invisibility. Fragments of an amaranth plant, collected on Friday night under a full moon, can even protect you against bullets... We wonder what Theophrastus would say to this?

The Amaranth and the Types of Immortality.—"Eternity points, in its amaranth bower" (Shelley, Bereavement, 1901). The quest for eternity and immortality is one of the major inquietudes of the human spirit. Physical or spiritual immortality, everlasting love and friendship, eternal happiness and virtue are different coordinates of the same obsessional geography of ideas. Amaranth was chosen as a symbolic flower to capture all of these meanings. That is why an exploration into the meanings of the amaranth name is at the same time a taxonomy of the types of immortality.

Immortal youth (life).—The first metamorphosis of the amaranth from an everlasting plant into an immortality symbol can be found in one of Aesop's fables (the Rose and the Amaranth, 384, 1975). The Amaranth, envious of the "beauty and perfume" of the Rose receives the following reply: "I indeed, dear Amaranth, flourish but for a brief season! If no cruel hand pluck me from my stem, yet I must perish by an early doom. But thou art immortal and dost never fade, but bloomest for ever in renewed youth" (Aesop, Fables: The rose and the amaranth, 384, 1975).

Immortal hero and everlasting virtue.—At the funeral of Achilles, Thetis and the Muses spread "immortal weeds" on his grave (Homer, "Odyssey" 24:43–29, 1955). According to more recent sources that we could not trace in classical authors, the Thessalians placed amaranth on the funerary monument of Achilles (Thylesius Antonius 1531) or wore amaranth crowns at his funeral (Genlis 1810–1811). For Cowper, "the only amaranthine flower on earth is virtue" (The Task, Book 3: The garden, 1874) and for Sainte-Beuve the amaranth is a "symbol of virtue that never fades" (Causeries du lundi, vol. 8:142, 1926 – 1947).

Immortal love and hope.—The following verses of Gombault were taken from Henry's Flora Historica (1829): "*Je suis la fleur d'amour qu'amarante on appelle/ Et qui vient de Julie adorner les beux yeux./ Roses, retirez-vous, j'ai le nom d'immortelle,/ Il n' appartient qu'à moi de couronner les dieux.*" The old Victoran name of *A. caudatus*, "love-lies-bleeding," is in direct relation with the shape and the blood red color of the inflorescence. "Hope without an object cannot live" and the amaranth is for Coleridge a symbol of eternal hope (Work without hope, 1972).

Immortal soul.—Although Pliny's description of the amaranth was utilitarian, his words were later interpreted in a symbolic or mystical way: "*mireque, postquam defecere cuncti flores, madefactus aqua revivescit et hibernas coronas*

facit. summa natura eius in nomine est, appellati, quoniam non marcescat" (Natural History 21:41, 1951). In the Roman Empire of the second century AD, the custom of wearing wreaths was regarded as a pagan practice by Tertullian (1992) and Clement of Alexandria (1965–1983), a sacrilege to the crown of thorns worn by Christ. For Clement, the amaranth became an imaginary immortal flower, which grew only in Paradise and was offered as an eternal reward to good Christians. "The earth is not capable of producing this flower; heaven alone knows how to grow it" (Pedagogos 2.8.73, 1965–1983). As Irwin (1990) pointed out: "Clement ... was certainly not simply transplanting an actual earthly flower to heaven." He was adding two new dimensions to Aesop's symbol of immortality: the spiritual and the sacred. More than 400 years after Clement, Milton envisions the same heavenly amaranth, but his vision of the "immortal amaranth" is purely metaphorical:

"With solemn adoration down they cast
Their Crowns inwove with Amarant and Gold.
Immortal Amarant, a Flour which once
In Paradise, fast by the Tree of Life
Began to bloom, but soon for mans offence
To Heav'n remov'd where first it grew, there grows,
And flours aloft shading the Fount of Life,
And where the river of Bliss through midst of Heaven
Rowls o're Elisian Flours her Amber stream"
(Book III, 351–360, and see also XI, 77–81, 1948).

Another, less solemn, type of heavenly amaranth can be found in Charlotte Brontë: "Happiness is a glory shining far down upon us, out of heaven. It is a divine dew which the soul, on certain of its summer evenings, feels dropping upon it from the amaranth bloom and golden fruitage of Paradise" (Brontë, Villete, Chapter 22, The letter, 1984).

Sacred amaranth.—In the 13th century, the name became an attribute of the Virgin Mary, a symbol of immaculate immortality: "*Amaranthus flos, sacro, qui non marcet, honore vigens*" (Johanes Germanus 1460 in Marraccio 1693). In a painting by Botticini, amaranth plants grow from the ruins of the palace of David where Madona adores the sacred child (D'Ancona 1977). In Southern Europe, amaranth was used to decorate churches on Ascension Day (Skinner 1925; Cole 1979), and some of the popular names included "the scourge of our Blessed Lord" (Dowling 1900) and "Discipline de Religieuse" (Henry 1829). It should noted that blood symbolistic, divine or not, is a convergence point between the Aztecs and the Old World.

Hermetic amaranth.—In 1653, Christina, Queen of Sweden, founded the hermetic Order of the Amaranth (Åkerman 1991). The emblem consisted of an insignia with a double A, a crown of amaranth, and the inscription "*dolce in nella memoria.*" Henry (1829) mentioned the above inscription as appearing on a medal with an Amaranth in enamel. The exact type of immortality sought

by Christina can only be speculated: catholic ideal of virginity, everlasting and imperishable glory or immortal mystical bond (see Åkerman 1991). At least one of the aims was achieved because the Queen is still "*dolceinnella memoria*." The emblem and the name have been embraced by the current Masonic Order of the Amaranth (Order of the Amaranth 1994).

A Plant or a Symbol?—"...Sad Amaranthus, in whose purple gore/...To whom sweet Poets hath given endlesse date" (Spenser, The Faerie Queene, book III, canto VI, 406–408, 1976). Hundreds of writers, poets and sometimes even musicians have carved and deepened (or occasionally weakened) the name of the amaranth. Some of them are probably not aware that the amaranth is an earthly plant and not an abstract sign or symbol. This particular case illustrates the disparity between the symbolism and the reality of many names. The dispute over the presence of an existential relationship between a name and the named thing recurs from Plato's Cratylus to modern semiotics. Whether the name is a simple convention (as Hermogenes believed in Cratylus, Plato, 1926), a sign that signifies (Wittgenstein, Tractatus logico-philosophicus:3, 1992), or more than that is not for us to determine. This name traveled in time from plant to plant until it found its perfect mach. Grain amaranths are "from the past for the future" (Cole 1979) and as weeds they will be "a perpetual source of trouble to farmers" (Macoun 1883). At the same time, the meanings conveyed by the name have probably changed our perception of the plants. Perhaps the amazing history of the *huauhtli* plants in the New World would have faded away without the unfading symbolism of their new name. One thing is certain: the amaranth will continue to grow, here or in Paradise as long as we do, or perhaps even longer.

ACKNOWLEDGMENTS

This paper would not had been written without the encouragement of Barney Lipscomb, for which we are deeply grateful. David Brenner, Susan Weaver, Melissa Wheeler and anonymous reviewer provided interesting observations, which improved the quality of the manuscript. Alexis Wimmer helped us with the Nahuatl language.

Haynes and Holm-Nielsen provide treatments of 17 neotropical species of *Potamogeton* and three neotropical species of *Stuckenia*. Included are keys, descriptions, illustrations, and documented distribution maps for the species and subspecies discussed."

DOCUMENTED CHROMOSOME NUMBERS 2003: 1. CHROMOSOME NUMBER OF *TOXICOSCORDION NUTTALLII* (LILIALES: MELANTHIACEAE) AND CLARIFICATION OF THE GENUS

Wendy B. Zomlefer

Department of Plant Biology
University of Georgia
2502 Plant Sciences
Athens, GA 30602-7271, U.S.A.

ABSTRACT

The mitotic chromosome count for *Toxicoscordion nuttallii* ($2n = 22$), reported here, matches the number formerly documented for other species in the genus. A previous unvouchered report of $2n = 32$ for this species, therefore, likely represents a misidentification, and a base number of $x = 11$ is synapomorphic for *Toxicoscordion*. An updated overview of this recently resurrected segregate genus is given.

RESUMEN

El recuento de cromosomas mitóticos en *Toxicoscordion nuttallii* ($2n = 22$), citado aquí, concuerda con el número documentado anteriormente para otras especies del género. Un reporte previo, sin catalogar, de $2n = 32$ para esta especie, probablemente representa una identificación incorrecta y el número base de $x = 11$ es sinapomórfico para *Toxicoscordion*. Aquí se presenta una revisión de este género segregado recientemente resucitado.

Tribe Melanthieae (Liliales: Melanthiaceae) comprises seven genera (ca. 62–93 spp.) of predominately woodland and/or alpine perennial herbs occurring mainly in the temperate to Arctic zones of the Northern Hemisphere: *Amianthium* (1 sp.), *Anticlea* (9–11 spp.), *Schoenocaulon* (24 spp.), *Stenanthium* (2–3 spp.), *Toxicoscordion* (8 spp.), *Veratrum* s.l. (17–45 spp.), and *Zigadenus* s.s. (1 sp.). These generic circumscriptions (most novel) are supported by recent parsimony analyses of *trnL-F* (plastid) DNA and ITS (nuclear ribosomal) sequence data (Zomlefer et al. 2001, 2003). A significant consequence of the molecular studies was the reassessment of the traditional *Zigadenus* s.l., a poorly defined assemblage with a complex taxonomic history (summary in Zomlefer 1997). Although several segregates of *Zigadenus* have been described, contemporary treatments (e.g., Schwartz 2002) have typically accepted only the monotypic segregate *Amianthium* with the remaining ca. 19 species maintained in *Zigadenus* s.l. Based on these molecular data, however, *Zigadenus* s.l. is polyphyletic and forms five strongly supported clades that correlate with certain geographical distribution, morphological characters, and chromosome number.

SIDA 20(3): 1085–1092. 2003

One well-defined clade corresponds to the genus *Toxicoscordion*, originally described by Rydberg (1903), and recognized as a distinctive taxon by both Preece (1956) and Schwartz (1994) as *Zigadenus* sect. *Chitonia* (R.A. Salisbury) J.G. Baker. This *Zigadenus* segregate comprises ca. eight species (Table 1) restricted to the midwestern United States to western North America (Fig. 1A) and includes the well-known poisonous "death camas" plants of the rangelands such as *T. nuttallii*, *T. paniculatum*, and *T. venenosum* (see Marsh et al. 1915, 1926). The resurrection of *Toxicoscordion* required one new combination (*T. fontanum*), a species described within *Zigadenus* by Eastwood (1937), long after Rydberg (1903) had circumscribed the genus and had transferred the appropriate contemporary *Zigadenus* species. *Toxicoscordion* is defined by the morphological synapomorphies of conspicuously clawed tepals (especially the inner three) and one obovate gland per tepal (Fig.1B; Zomlefer et al. 2001; Zomlefer & Judd 2002). Although a discrete genus, specific and infraspecific limits are unclear, especially within the variable *T. micranthum–T. fremontii* species complexes and the intergrading *T. paniculatum–T. venenosum*. For example, in an isozyme study of these species (Schwartz 1994), the monophyly of *T. paniculatum* is suspect because the five sampled populations were separated from each other in UPGMA cluster analyses and distance Wagner trees. These results warrant further examination of the species complexes in the genus.

The chromosome number $2n = 22$ (or $n = 11$) has been reported for all species of *Toxicoscordion* (Table 1; Fig. 2) except for one anomalous report of $2n = 32$ for *T. nuttallii*. Since chromosome number is a significant and likely an invariable apomorphy for genera of tribe Melanthieae (e.g., Zomlefer and Smith 2002), 22 is the predicted mitotic count for all *Zigadenus* species now transferred to *Toxicoscordion*. This study challenges the earlier conflicting *T. nuttallii* report, thereby seeking to validate the diploid number of 22 as a consistent synapomorphy for the genus.

MATERIALS AND METHODS

Several bulbs of *Toxicoscordion nuttallii* were collected during April 2002 at two localities in south-central Texas by J. Spangler and T. Wendt (see Table 2) and transplanted to pots maintained at the Plant Biology Dept. Greenhouse Facility at the University of Georgia. Dividing root tip cells were prepared for examination with some modification of the general protocols outlined by Flory and Smith (1980) and Jones and Luchsinger (1986). Once the plants were well-established, actively growing root tips were harvested at 8:00 AM and treated with 0.2 % colchicine for 4 hours, rinsed in distilled water, and then fixed in Carnoy's solution (3 ethanol: 1 acetic acid) overnight or longer. Following this fixation, the roots were rinsed in distilled water and stored under refrigeration in 70% ethanol. The material was subsequently hydrolyzed in 1.0 N HCl at 53° C for 5 minutes, rinsed several times again with water, and treated with 45%

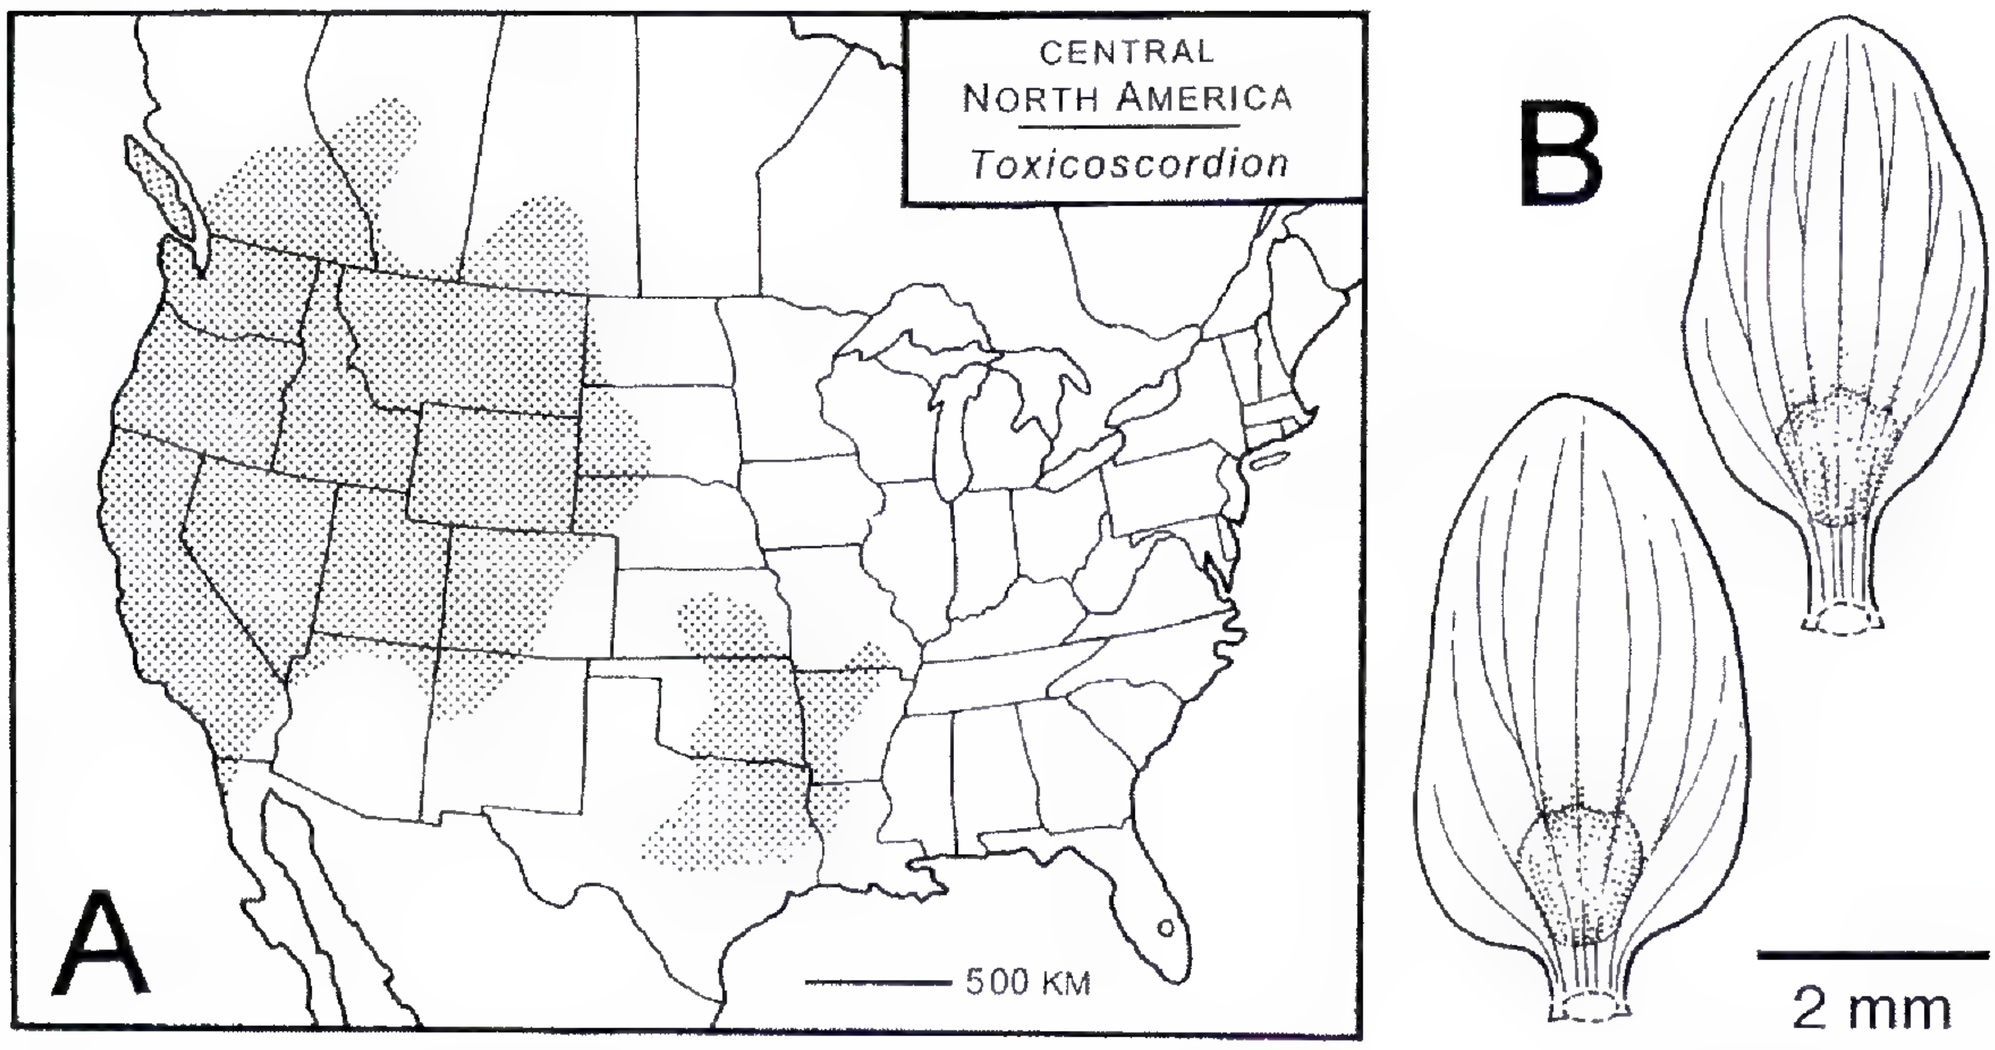

FIG. 1. Distinctive characteristics of *Toxicoscordion*. **A.** General distribution map of *Toxicoscordion* (data from Walsh 1940; Preece 1956; Schwartz 1994, 2002; M. H. MacRoberts pers. comm.). The midwestern disjunct range (Texas–Oklahoma–Kansas–Missouri–Arkansas–Louisiana) comprises the localities of *Toxicoscordion nuttallii*. **B.** Adaxial surface of an outer (left) and an inner (right) tepal from *T. nuttallii* (*Rollins 5334*, GH), showing the generic autapomorphies: claw plus a single obovate gland. Dashed ellipse = filament insertion. The claws of the inner tepals are typically more pronounced than those of the outer whorl.

glacial acetic acid for 10 minutes. The growing tips were then removed, macerated with a dissecting spatula on a glass microscope slide, and stained with 1% aceto-orcein. After application of a cover slip, the slide was gently heated with an alcohol lamp, placed between blotters, and subjected to additional pressure. Slides were mounted in euparal for future reference. Well-spread metaphase (and late prophase) chromosomes were traced under a Leica DMLB Research Microscope with a camera lucida attachment. Herbarium specimen vouchers (Table 2) are deposited at GA and TEX.

RESULTS AND DISCUSSION

The mitotic chromosome number of $2n = 22$ for *Toxicoscordion nuttallii* is confirmed with plants from populations in Hays and Williamson Counties, Texas (Fig. 2E, F; Table 2). A citation of $2n = 32$ for *T. nuttallii*, originally reported by Zakharieva and Makushenko (1969) and subsequently cited in various indices and floras (e.g., Fedorov 1969; Moore 1971, 1973; Churchill 1986; Yatskievych 1999), was based on an undescribed and unvouchered plant then growing at the Munich Botanical Garden (original source not cited). This "*Zigadenus*" species was likely an *Anticlea*, another *Zigadenus* segregate, but one characterized by $x = 8$ (Zomlefer & Judd 2002).

Chromosome number is a useful taxonomic character for genera within tribe Melanthieae, especially the synapomorphic $2n$ numbers of 20 for

TABLE 1. The species of *Toxicoscordion* and their mitotic (*2n*) and/or meiotic (*n*) chromosome numbers. The single citation for *T. nuttallii*, *2n* = 32, is inconsistent with reports for all other species in the genus.

Taxon	Chromosome Number n	2n	Secondary Citation(s) in Indices and Floras	Original Source(s)

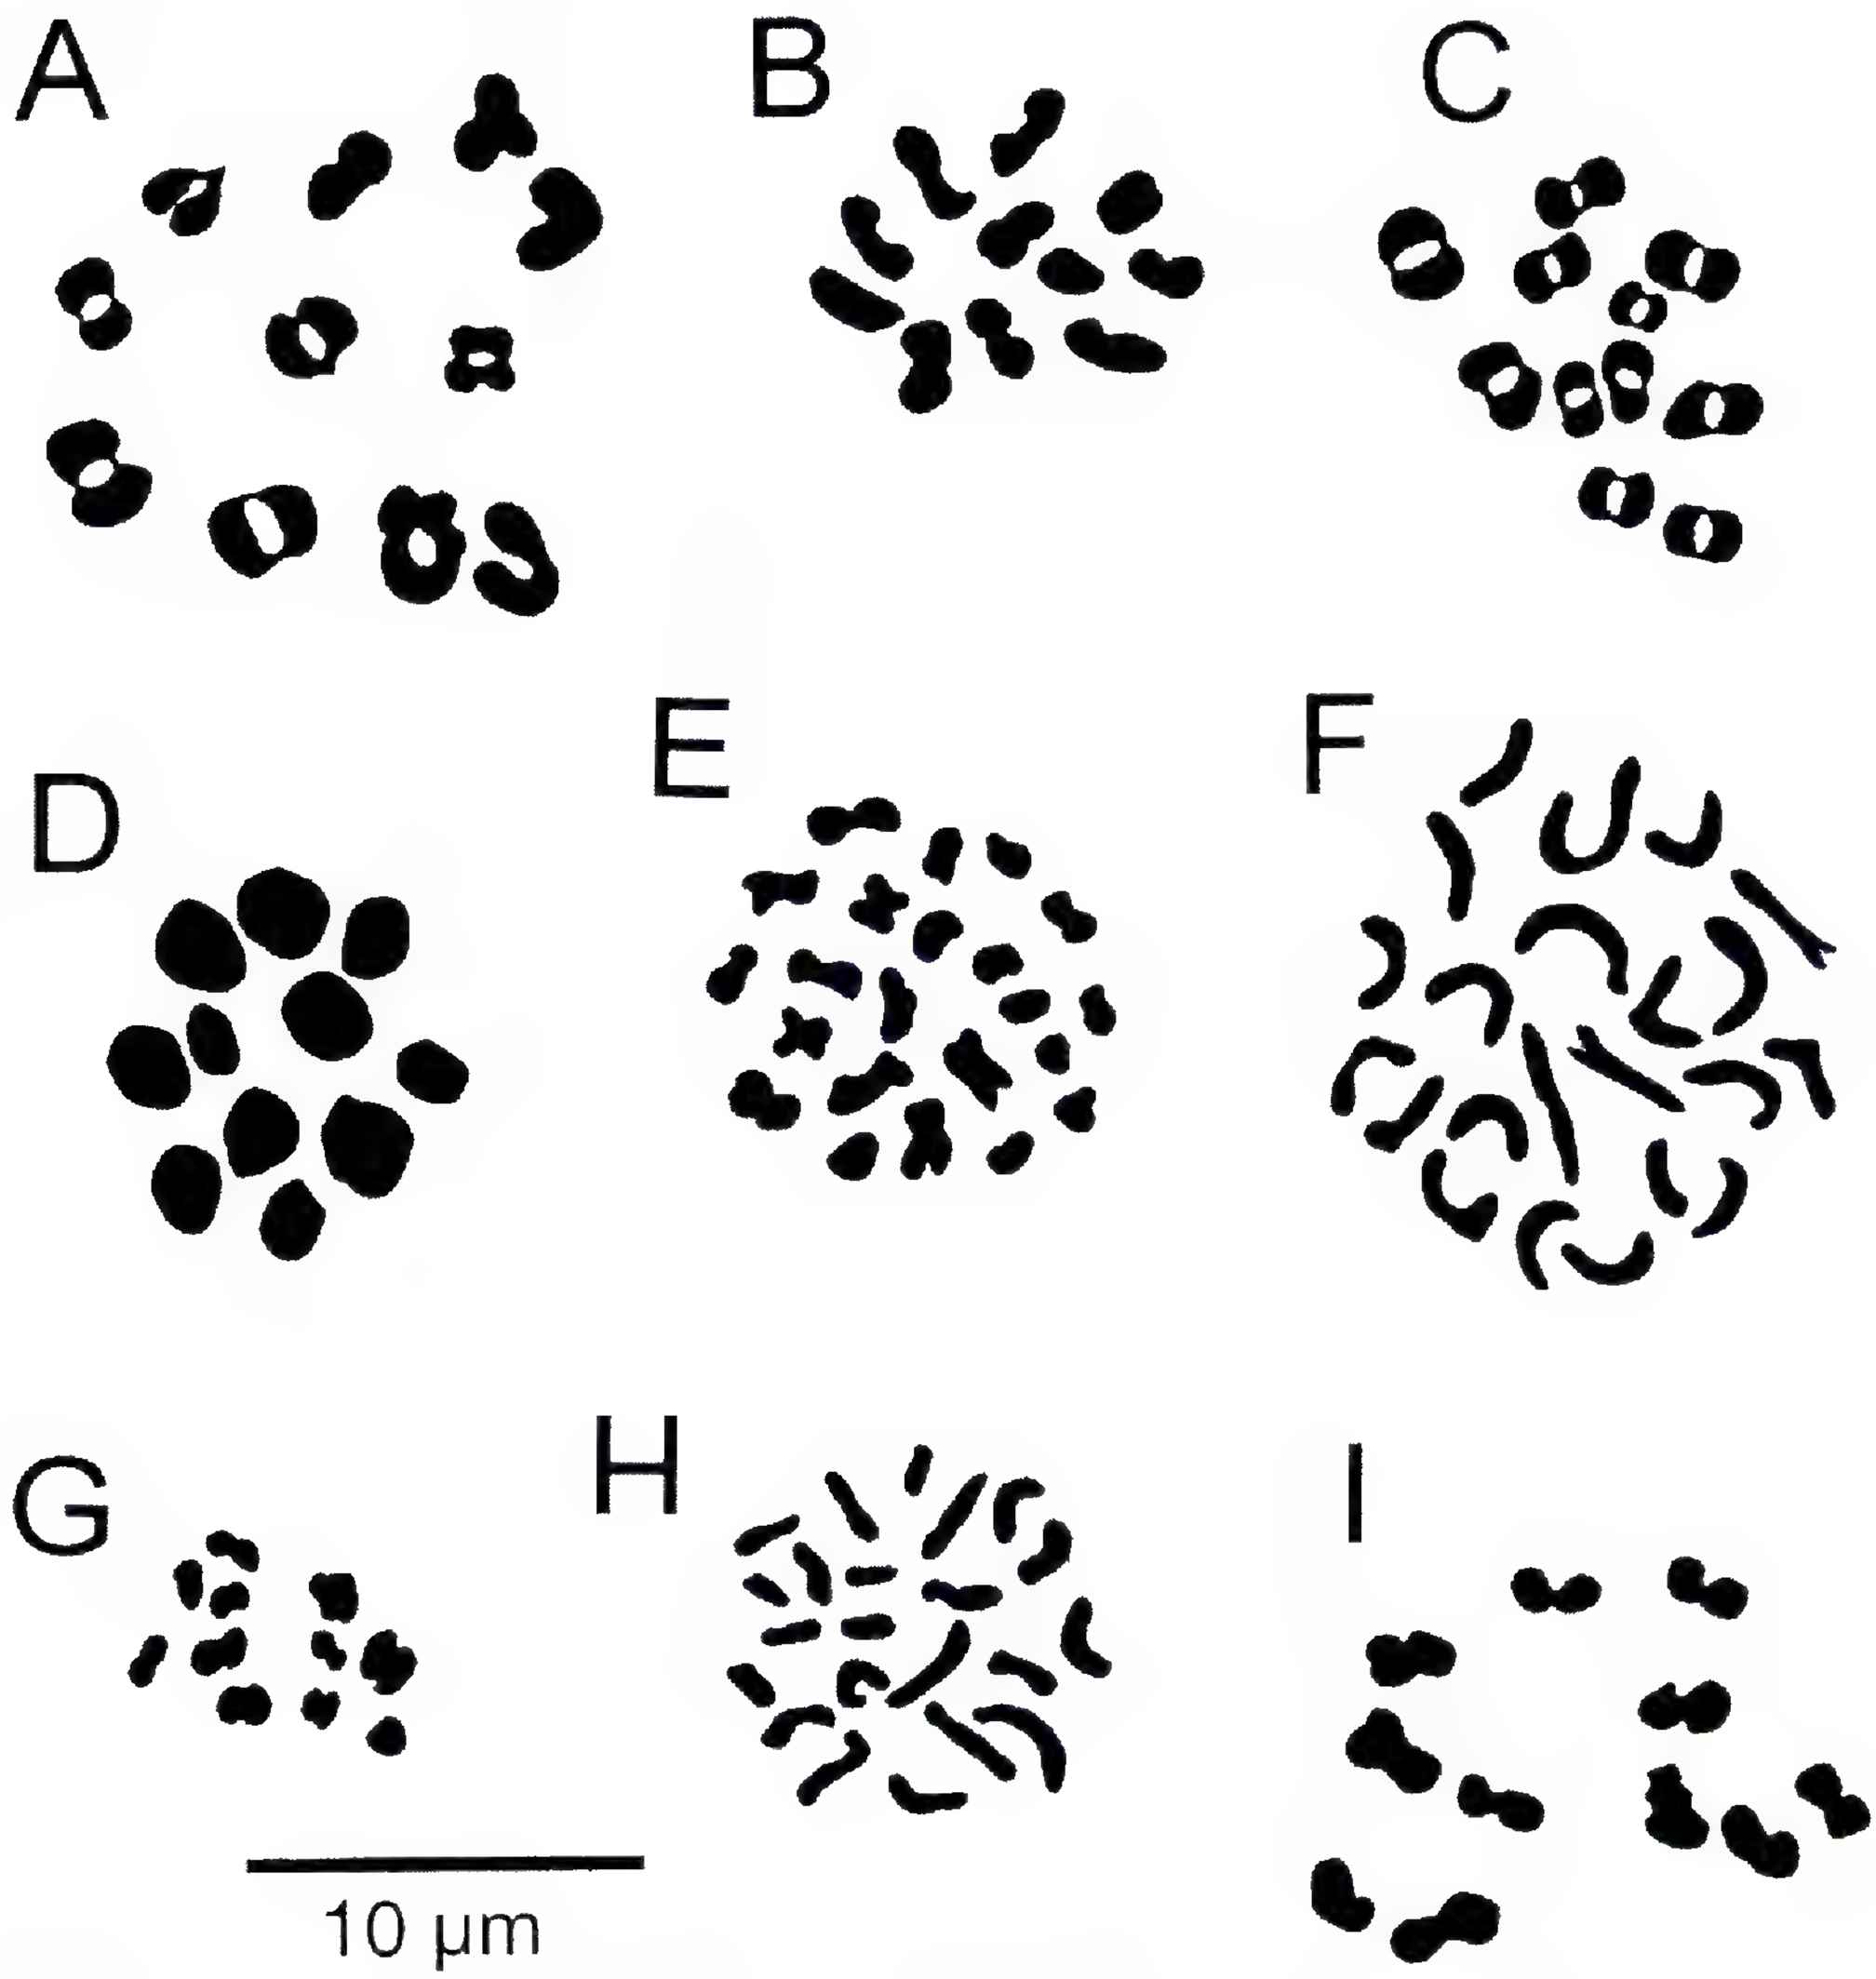

FIG 2. Summary illustration of previously documented meiotic ($n = 11$) and/or mitotic ($2n = 22$) chromosomes of *Toxicoscordion* (A–D, G–I) and the new reports for *T. nuttallii* (E, F: $2n = 22$). **A.** *T. brevibracteatus*, diakinesis ($n = 11$). **B.** *T. fontanum*, anaphase II ($n = 11$). **C.** *T. fremontii*, metaphase I ($n = 11$). **D.** *T. micranthum*, metaphase I ($n = 11$). **E.** *T. nuttallii* (*Wendt 7246*, TEX), metaphase ($2n = 22$). **F.** *T. nuttallii* (*Spangler s.n.*, GA), late prophase ($2n = 22$). **G.** *T. paniculatum*, metaphase ($2n = 22$). **H.** *T. paniculatum*, metaphase I ($n = 11$). **I.** *T. venenosum*, metaphase I ($n = 11$). Figures A, B, and I modified from Cave (1970); Figs. C, D, G, and H modified from Preece (1956).

Stenanthium (Zomlefer & Judd 2002) and 22 for *Toxicoscordion*. A probable base chromosome number of $x = 8$ is often cited for the tribe (Sen 1975; Tamura 1995; Lowry et al. 1987; Zomlefer 1997), and multiples of this number are prevalent in other genera of the tribe: *Amianthium* ($2n = 32$), *Anticlea* (including *Stenanthella*; $2n = 32$), *Schoenocaulon* ($2n = 16$), and *Veratrum* (including *Melanthium*; $2n = 16, 32, 64, 80, 96$). Due to the small size of the chromosomes

TABLE 2. Voucher specimens for the chromosome numbers of *Toxicoscordion nuttallii* reported in this study.

Taxon	Locality and collection number (voucher location)	Mitotic chromosome number (2n)
Toxicoscordion nuttallii	TEXAS. HAYS CO.: Between Driftwood and Dripping Springs, along FM 150, 3.7 mi N of FM 1826, 15 Apr 2002, *Wendt 7246* (TEX)	22
	TEXAS. WILLIAMSON CO.: Austin, 0.25 mi from 8521 Foxhound Tr., 3 Apr 2002, *Spangler s.n.* (GA)	22

(ca. 2.0-4.0 μm in length), however, the few detailed karyological studies (e.g., Lee 1985) lack the detail to infer mechanisms of chromosomal evolution, although these chromosome numbers indicate the prevalence of polyploidy and/or aneuploid variation of the prospective basic number. The validation of $2n = 22$ for *T. nuttallii* strengthens support for the monophyly of *Toxicoscordion*, as well as the phylogenetic significance of chromosome numbers as generic synapomorphies for tribe Melanthieae.

ACKNOWLEDGMENTS

Jason Spangler and Tom Wendt (TEX) generously provided live bulbs of *T. nuttallii* collected in the field. David E. Giannasi contributed his expertise with the laboratory work, kindly shared reagents and equipment, and also reviewed a draft of the manuscript. I am grateful also to Michael Boyd and Andrew W. Tull (Plant Biology Dept. Greenhouse Facility, University of Georgia) for reviving and maintaining plants shipped from the field; Walter S. Judd and Dale E. McNeal for editorial comments; Emily Wood for assistance at GH; Robert J. Liebermann for translating Russian text; James L. Zarucchi for providing a copy of the in-press *Zigadenus* treatment from the *Flora of North America*; and William Carromero for the Spanish translation of the abstract. Funds provided by the University of Georgia Department of Plant Biology financed laboratory materials.

A COMMUNITY-LEVEL FLORISTIC RECONNAISSANCE OF THE RAJA AMPAT ISLANDS IN NEW GUINEA

W. Takeuchi

Herbaria and Arnold Arboretum of Harvard University
Research Associate, PNG National Forest Authority
PNG Forest Research Institute
P.O. Box 314
Lae, Morobe Province 411, PAPUA NEW GUINEA

ABSTRACT

The Raja Ampat district of Indonesian Papua is one of New Guinea's most unusual floristic environments. A recent rapid-assessment survey examined vegetation patterns across the district, characterizing the major plant communities and identifying existing biodiversity threats. Mangroves, beach forest, lowland hill forest, limestone karst, and ultrabasic (serpentine) woodland were the principal natural-growth habitats explored by the botanical team. Although several lowland areas are being degraded by concessional logging, most of the limestone communities remain in pristine condition. There are substantial prospects for future taxonomic discovery.

KEY WORDS: botanical survey, limestone karst, Papua, serpentine, ultrabasics

ABSTRACT

インドネシア領パプアのラヤアンパット地域はニューギニアの最も特徴ある植生地域の一つである。最近のラピッドアセスメント調査において、地域の植生パターン、植物群落の特徴、存在する生物多様性破壊の危機について調べられた。マングローブ林、海岸林、低地丘陵林、石灰岩カルスト、超塩基性土壌（蛇紋岩）林が今回調査を行った主な自然植生帯である。幾つかの低地林は商業伐採による植生の撹乱が見られたが、殆どの石灰岩土壌地域は原植生の状態を保っており、分類学上の価値ある発見がされる可能性が高いと思われる。

キーワード：植生調査、石灰岩カルスト、パプア、蛇紋岩、超塩基性土壌

INTRODUCTION

Located at the far western end of New Guinea, the Raja Ampat islands (Figs. 1, 2) are one of Malesia's little-known environmental jewels. In addition to spectacular coastal vistas deserving of World Heritage recognition, recent studies have determined that the islands probably have the highest levels of coral and reef fish diversity in the world (Reefbase 2002). Floristically, the Raja Ampat contain 3 of the 22 Papuan areas recognized as centers of very high endemism (Supriatna 1999).

Most of western New Guinea (including Misool and northern Salawati) are

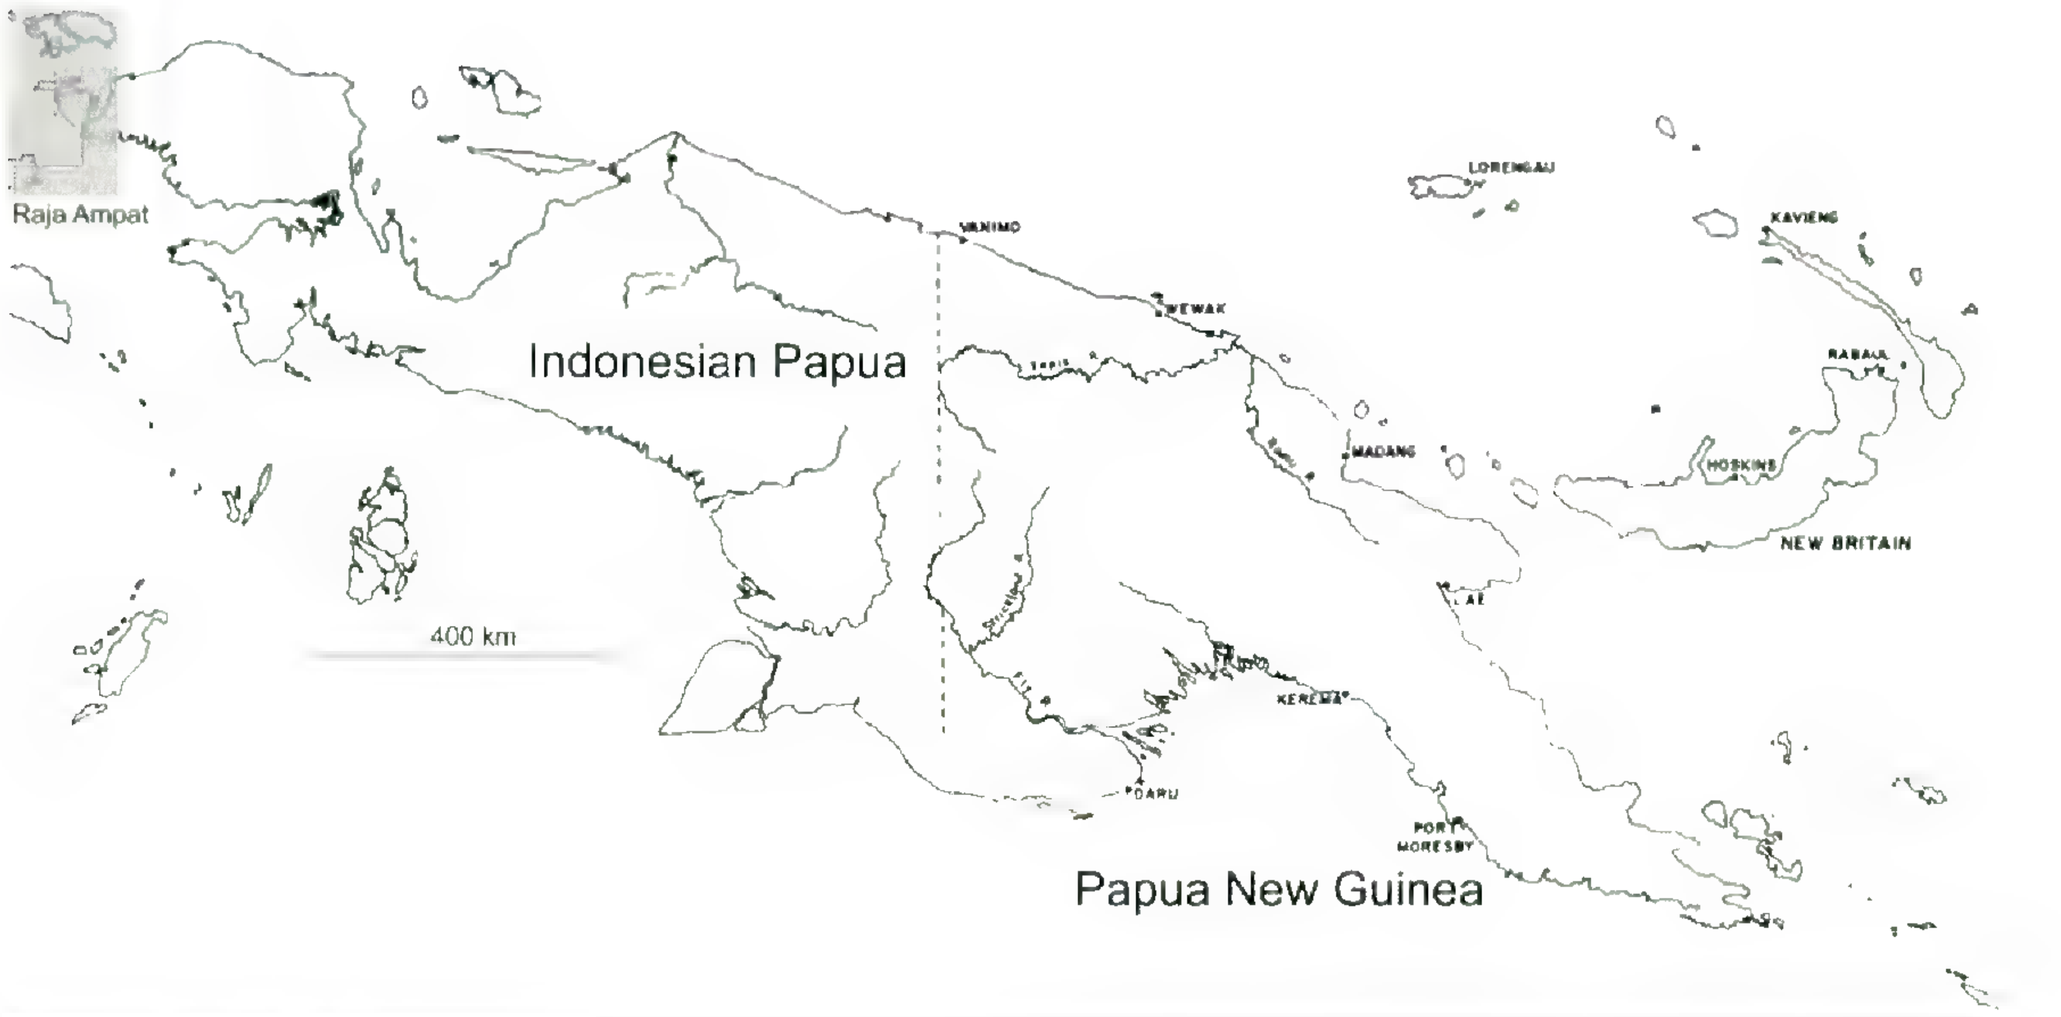

Fig. 1. Island of New Guinea. Shaded area: Raja Ampat district.

part of a Papuan microcontinent which separated from the Gondwanic landmass during the early Mesozoic, subsequently drifting into its present position independently of the Australian craton (Pigram & Panggabean 1984; Pigram & Davies 1987; Hall 1998). Waigeo and adjacent islands comprise one of only two oceanic terranes in this region of New Guinea. Especially in the westernmost islands, ultrabasic and limestone substrates have developed distinctive plant communities containing many endemic species.

Ironically, considering the overall paucity of information for such environments, the Raja Ampat was among the first areas to be visited by early explorer-naturalists to eastern Malesia. In 1792–93, the vessels *Recherche* and *Esperance* obtained plant collections from Waigeo as part of a general program of regional exploration. Botanical specimens were also taken during visits by the *Uranie* and *Physicienne* in 1818–19, and during the cruise of the *Astrolabe* (1826–29). Early collectors included Beccari (1872–73) on Batanta and Kofiau, and Micholitz in 1890, also on Batanta. Frodin and Gressitt (1982) provide a general account of these early activities. Following the efforts of Cheesman on Waigeo (1938–39) and by Royen on Batanta and Waigeo (Royen 1960), there was little serious work in the district. Most of the interior sections remain unknown because of the physical difficulties of access and the nearly total absence of service infrastructures.

MATERIALS AND METHODS

The Nature Conservancy (TNC) survey of the Raja Ampat was designed primarily to investigate the diverse reef ecosystems of the area, and secondarily to identify linked land-marine conservation targets for possible community-based initiatives. During a 3-week period (Oct. 30 to Nov. 22, 2002) the scientific team

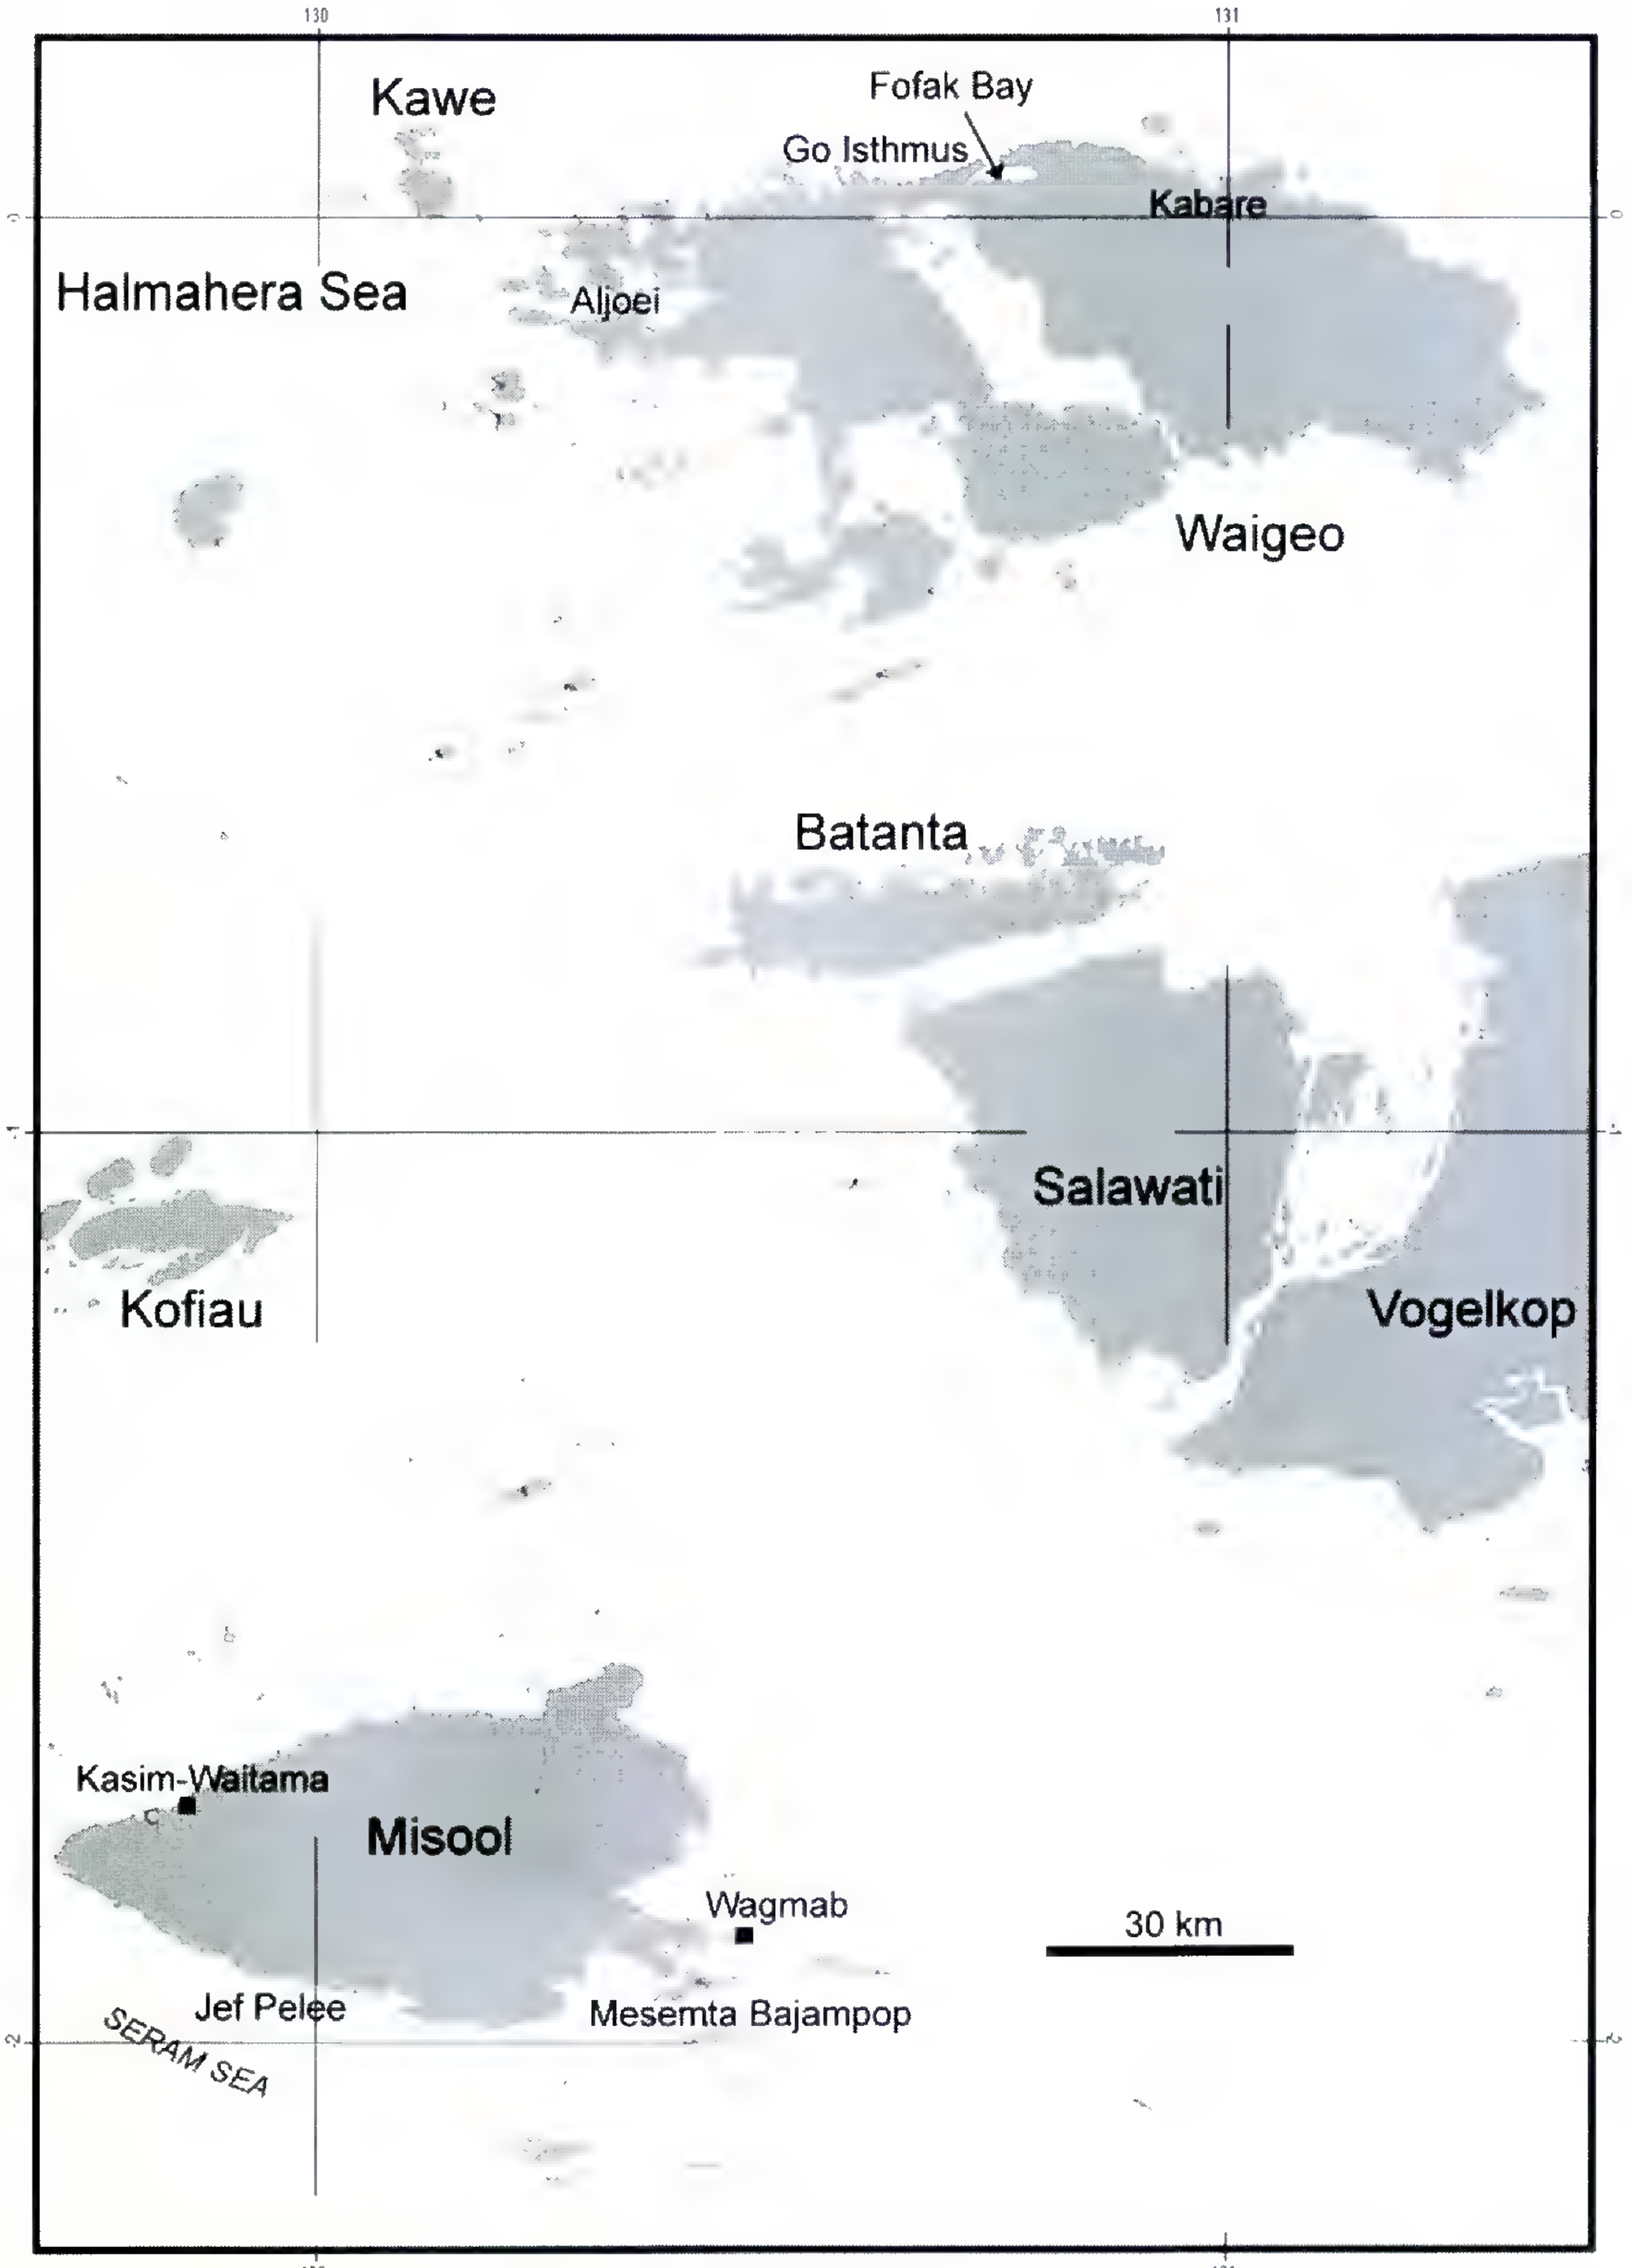

FIG. 2. Raja Ampat District. Principal localities from the TNC biological reconnaissance. Sayang and Wayag islands are (respectively) 35 and 17 km NW of Kawe and outside the map boundaries.

made numerous stopovers among all the main islands, using a chartered diving vessel (the *Pindito*) as a live-aboard mobile base. As ecologist for the forest assessment, the writer was responsible for describing the principal vegetation types and ground-truthing perceived community distributions against a preliminary classification developed from the RePPProT (Regional Physical Planning Program for Transmigration) plant typology maps (RePPProT 1990; Hardiono 2002). The floristic evaluations and botanical collecting were conducted with assistance by Duncan Neville (TNC Sulawesi Manager), Johanis Mogea (Herbarium Bogoriense), and Fery Liuw (Departemen Kehutanan Papua).

Forest communities were examined in *ad hoc* fashion, via walk-through assessment of areas accessed by dinghy or speedboat (Figs. 3–5). Community variation was documented by numerous photographs referenced with readings from a handheld GPS recorder. These onshore activities were necessarily constrained by the collateral marine studies and the corresponding movements of the *Pindito*. Because of the constantly shifting itineraries of the marine team, the forest participants could usually devote only one day to a given site, thus restricting survey coverage to areas near the coast.

Botanical collections were typically made in sets of 5 duplicates whenever fertile specimens were found. Gatherings were field-packed in newsprint and plastic bags, then soaked with 70% ethanol for subsequent processing at Herbarium Bogoriense (BO). Silica-dried samples for DNA sequencing were also obtained if specialists had placed earlier requests for assistance. In order to simplify the vouchering process, collections were numbered under the sequence of botanist J. Mogea. Specimen distributions will occur from BO, with A, K, L, and MAN as the principal recipients (Irawati pers. comm.). A taxonomic account of the botanical findings is being prepared by Mogea for separate publication.

RESULTS

Botanical observation and collecting were complicated by drought conditions caused by the recent El Niño disturbance. The collections tally (550 nos.: Mogea et al. 7726–8276) includes about 100 sterile numbers because of the unfavorable phenology. Although the entire district showed signs of drought stress, the severity of the disturbance was greatest in the outer islands (Misool, Kawe, and Waigeo; Fig. 6). At Batanta and Salawati, forest canopies were mostly green (although understories were very dry) and there were even brief periods of torrential rain during the visit to those islands.

Among the habitats covered by the TNC-modified RePPProT forest classification, mangroves were apparently the only natural-growth community which could be accurately mapped using Landsat reflectance patterns (see Hardiono 2002). Topographic and geological maps proved of greater value than any existing forest typing system. The lack of a GIS-based classification equivalent to the Papua New Guinea Resource Information System (PNGRIS) and its

Fig. 3. Land team members (Duncan Neville and Fery Liuw) boarding a zodiac after surveying an island in the Jef Pelee group. The 75–ft Pindito lies anchored offshore. Zodiac and speedboat tenders provided daily transport for the land-sea survey. Photo November 9, 2002.

Fig. 4. For travel over longer distances, the team used a speedboat ('longboat') of a versatile design widely employed in the Papuan coastal and riverine traffic. Despite their unwieldy appearance the shallow-draft longboats are capable of entering the headwaters of even small streams. A survey longboat is shown here at Wagmab Island. Photo November 4, 2002.

generically related Forest Inventory Mapping System (FIMS), is a serious obstacle to survey planning in western New Guinea (see Bellamy & McAlpine 1995; Hammermaster & Saunders 1995a, b). To facilitate comparisons with the FIMS classification, the following community descriptions are prefaced by the structural code (in parentheses) for the corresponding formations in East New Guinea.

The expedition included 15 fulltime participants, of which 5 were journalists or photographers. As a result of the intensive media coverage, survey images and preliminary findings are available on several websites (http://www.reefbase.org/RajaAmpat/; http://www.AliensOfTheSea.com/HDTV; http://www.projectbirdwatch.org/rajaampatrea/).

Principal Communities

Mangroves.—(M) Of all the vegetation types encountered on the survey, the mangrove communities are probably the best-studied (e.g. Backer & Steenis 1951; Ding Hou 1957, 1958, 1960; Percival & Womersley 1975; Floyd 1977; Duke & Jackes 1987; Erftemeijer et al. 1989; Duke 1991; Mabberley et al. 1995). Unlike the situation in nearby Telek Bintuni (cf. Erftemeijer et al. 1989; Takeuchi et al. in press), Raja Ampat mangroves are insignificant and markedly impoverished, except in a few places where estuarine flats and tidal rivers have provided ample habitat for the *Bruguiera-Rhizophora* associations (Fig. 7). Among investigated

FIG. 7. Wayag Island. Interior view of a mangrove forest on limestone karst. Trees are represented mostly by *Bruguiera gymnorrhiza* and *Rhizophora mucronata*. Photo November 16, 2002.

sites, the best examples of this community were seen on Pulau Misool, along the lower Gam and Kasim rivers. At the second locality, there is a well-developed upstream sequence (in order) of *Rhizophora mucronata – Ceriops tagal*, *Bruguiera gymnorrhiza*, *Nypa fruticans*, then a final freshwater assemblage consisting of *Xylocarpus granatum*, *Dolichandrone spathacea*, and *Heritiera littoralis*. However in most parts of the archipelago, mangroves are represented (if at all) only by isolated trees along a foreshore, with no horizontal development of the community.

Swamp woodland.—(Wsw) Monodominant forests of *Metroxylon sagu* (sago) are scattered through the Raja Ampat district, wherever soil flooding is severe. The occurrences are insensitive to substrate. Sago swamps are found on limestone at Kofiau (01°09'25S, 129°51'38E), and on mineral clays at Kapatlap, Salawati. Although the floristic diversity is very low, sago communities are of considerable subsistence value as a source of dietary starch obtained from the *Metroxylon* trunks (cf. Powell 1976; Johns & Hay 1984).

Littoral or beach forest.—(B) A distinctive community along many coastlines, beach forests are mostly composed of widely distributed, even pantropical taxa, but have been reduced over much of their former range because of anthropogenic pressures (Wikramanayake et al. 2001). The principal indicator species for this community are *Calophyllum inophyllum*, *Hibiscus tiliaceus*,

Fig. 8. Open beach forest on Wagmab. In the western Raja Ampat, mangroves and beach forest are generally scarce. The limestone and serpentine vegetation often extend to the highwater line, displacing the beachfront communities more characteristic of other coastal areas. Photo November 4, 2002.

Pandanus tectorius sens. lat., *Terminalia catappa*, and *Thespesia populnea* (Fig. 8). In the Raja Ampat other associates often included *Colubrina asiatica*, *Parsonsia alboflavescens*, *Derris indica* (*Pongamia pinnata*), *Tacca leontopetaloides*, *Ximenia americana* var. *americana*, and *Vigna marina*. Beach forest generally occurs on sand or coralline rubble behind the strand zone. A particularly good example was seen at N Kofiau (01°09'24S, 129°50'47E). On uninhabited Sayang Island (0°16'24S, 129°53'47E), a different type of beach association (BCe) was recorded on sandy flats, consisting of *Casuarina equisetifolia*, *Scaevola sericea*, *Sophora tomentosa* ssp. *tomentosa*, *Spinifex littoreus*, and *Tournefortia argentea*.

Lowland forest on deep mineralized soil.—(Pl, Hm) The land team encountered this community type near Kapatlap on Salawati, and on the north and south shores of Batanta, where the vegetation is predominantly a tall stature rainforest similar to those from coastal lowlands of the Bomberai Peninsula. Deep soil habitats (in the eastern Raja Ampat) were probably the most speciose of all the surveyed environments, but were also characterized by plants common in adjacent mainland areas and thus of comparatively low conservation interest (Figs. 9, 10). *Intsia bijuga*, *Koordersiodendron pinnatum*, *Pometia pinnata*, and *Terminalia* cf. *copelandii* were dominant trees in such situations, with *Celtis*, *Ficus*, *Dysoxylum*, *Myristica*, and *Syzygium* the best-represented genera in the subcanopy. The regrowth phase included *Alstonia scholaris*, *Gastonia serratifolia*, *Morinda citrifolia*, and *Trema cannabina* as the most prominent species, at least within the logged-over tracts seen on Batanta and Misool.

In the western Raja Ampat, deep soil habitats are generally absent except in the flood plain of large rivers (e.g. Gam and Kasim rivers), or in the ravines on limestone karst (e.g. the numerous islets near Mesemta Bajampop of SE Misool). Such areas have tall forests comparable to the Batanta/Salawati formations, but are species-poor and usually less than 1 ha in size (Figs. 11–13). Frequently, the stands are composed of *Intsia bijuga*, *I. palembanica*, *Vatica rassak*, or *Pometia pinnata*; with *Jagera javanica* ssp. *javanica*, *Trophis philippinensis*, *Teijsmanniodendron bogoriense* (uncommon), and *Maniltoa* spp. (*M. plurijuga* and *M. schefferi*) underneath. *Flindersia amboinensis* and *F. laevigata* var. *heterophylla* are conspicuous emergents in these tall-forest pockets on the smaller islands, particularly in the Misool group. *Osmoxylon sessiliflorum* was especially prominent in subcanopies near rivers (Misool). At Jef Pelee (S. Misool) a *Homalium foetidum* monodominant forest was encountered on ridge slopes and crests (Figs. 14, 15; 02°01'09S, 130°01'28E).

The forest understories in the Raja Ampat are harder to characterize. Generally when the canopy has at least 25–50% closure the groundlayer is already clear. Representative communities in the Misool group had either an open understory, or a palm-dominant layer of *Licuala* and rosette-stage *Calamus* (Figs.

Fig. 9. Forest understory on south Batanta, generally species-rich in comparison to the outer Raja Ampat. Photo November 3, 2002.

Fig. 10. Batanta. Lowland coastal forest on deep soils, in the process of conversion to subsistence gardens. Tall canopies (>30 m height) are common on islands close to the New Guinea mainland (i.e. Batanta and Salawati) but are essentially absent on the outer islands. Photo November 3, 2002.

Fig. 11. Wagmab. Forest in broad ravine. Communities are denser, taller, and richer than the surrounding vegetation on higher slopes. Photo November 4, 2002.

Fig. 12. Interior view of the forest shown in Fig. 11. Photo November 4, 2002.

Fig. 13. Alluvial forest along the Kasim River of western Misool. Photo November 10, 2002.

Fig. 14. Misool. Interior perspective of a *Homalium foetidum*-dominant forest on ridgecrests. Photo November 9, 2002.

16, 17). Ferns, herbs, and cryptogams were hardly ever seen, but it is not known to what extent their absence was due to the severe drought conditions then prevailing. Understories with diverse fern populations (*Bolbitis, Davallia, Drynaria, Nephrolepis, Sphaerostephanos, Tectaria*) were found only in riverine forest near Fanfanlap (W Misool) and at Kofiau (e.g. 01°10'01S, 129°50'30E).

Secondary forests.—(W) A substantial but unknown percentage of the Raja Ampat lowlands has been logged by industrial operators and is presently in various stages of recovery. The secondary forests examined by survey were previously cut at periods ranging from 15 to 30 years ago and are very distinct from more mature communities in the same habitat.

At Kofiau (01°11'03S, 129°43'21E) a 15–year regrowth (Figs. 18, 19) was a depauperate woodland of *Vitex cofassus, Morinda citrifolia, Conandrium polyanthum*, and *Ficus* spp. (mainly *F. microcarpa* and *F. prasinocarpa*). *Lunasia amara* var. *amara, Leea indica*, and various *Antidesma* and *Macaranga* spp. formed a sparse underlayer. In contrast, an adjacent section of unlogged forest was a closed canopy *Pometia*-dominant community with high frequencies of *Diospyros, Horsfieldia*, and *Knema*.

On Sayang (a flat sandy island completely logged in 1984; 0°16'38N, 129°53'48E), the regrowth was of similarly depleted composition, consisting for the most part of a remnant *Artocarpus-Intsia-Pometia* canopy with a second

Fig. 17. Kawe. Characteristic appearance of an understory from serpentine stands in ravines and valleys. Stems are generally of small diameter and herbaceous growth is sparse. The ground layer often has seedling crops of the canopy taxa. Ferns and gingers are conspicuously absent. Photo November 18, 2002.

FIGS. 18 and 19. Kofiau. Regrowth community from a former forest clearfelled 15 years ago. Photo November 12, 2002.

story of *Calophyllum inophyllum* and *Aglaia argentea* (the last species previously unrecorded for the Raja Ampat, cf. Pannell 1992). *Conandrium polyanthum*, *Codiaeum variegatum* var. *moluccanum*, and *Polyscias cumingiana* were undergrowth species. Dense seedling crops of *Pometia pinnata* often carpeted the ground in spite of drought conditions.

On a number of small islands, repeated anthropogenic disturbances have erased the former forest and a grassy fire disclimax (G) is now all that exists. At Jef Pelee (coral platform: 02°07'03S, 130°19'00E) most of the land surface is covered by a seral community of *Imperata conferta* with *Ischaemum muticum* on the seaward fringe (Fig. 20).

At Mesemta Bajampop a single example was seen of an early succession on karst, consisting of *Dracaena angustifolia* and *Commersonia bartramia*, with an extensive underlayer of *Gahnia aspera* (Fig. 21).[1]

Savanna.—(SaMl) Grassy savannas were recorded only on W Misool, at the mouth of the Kasim River and further inland near the Waitama tributary (01°47'23S, 129°53'57E and 01°51'41S, 129°55'05E respectively). The Kasim com-

[1]These sort of communities are the result of localized disturbance and are too small to be mapped by forest classification systems.

Fig. 20. Jef Pelee. Anthropogenic sedge-grassland (*Imperata-Ischaemum-Scleria*) on limestone islands near the Misool mainland. Other seral taxa included *Desmodium umbellatum*, *Premna serratifolia*, *Morinda citrifolia*, and *Pandanus tectorius*. Photo November 8, 2002.

Fig. 21. Mesemta Bajampop. A seral community on karst, consisting exclusively of *Commersonia bartramia*, *Dracaena angustifolia*, and *Gahnia aspera*. Photo November 5, 2002.

munities were *Melaleuca* dominant, but also included smaller individuals of *Pandanus tectorius* and *Timonius timon* in a distinct second layer (Figs. 22, 23). The dense 2 m+ groundcover was composed of *Ischaemum barbatum* and *Imperata conferta*, together with scattered patches of taller *Saccharum spontaneum* (Fig. 24). Indications of recent burn suggest that the Kasim savanna is probably periodically fired.

The Waitama savannas are larger than the Kasim communities and include *Eucalyptus* cf. *papuana* in addition to the more common *Melaleuca leucadendron* sens. lat. (Fig. 25). Shrubs were commonly represented by *Baeckea frutescens*, *Decaspermum bracteatum*, *Melastoma malabathricum* ssp. *malabathricum*, and a *Polyscias* sp. The groundlayer of *Ischaemum barbatum* and *Rhynchospora rubra* was habitat-partitioned, the latter species mainly occupying flat areas with the poorest drainage.

In appearance and composition the Waitama savannas are nearly identical to comparable formations on the Papuan mainland at Bomberai (cf. Takeuchi et al. in press). The communities at both sites are apparently under substrate control, with characteristic occurrences on flat or gently undulating terrain underlain by hardpan and alumina deposits (pers. obs.). Although the savannas in the Raja Ampat are affected to some degree by fire, the substrate patterns suggest the communities are a longterm response to stable edaphic factors (cf. Paijmans 1976).

Lowland forest on limestone karst.—(Hs, HsCp)[2] The limestone terrain is one of the most visually stunning and unspoiled environments in the Raja Ampat district. Much of this habitat is a deeply dissected karst which is often extremely difficult and time-consuming to traverse. A small hill can take an entire morning to ascend, so it is not hard to comprehend the relative lack of botanical collections from such areas.

Excellent examples of karst vegetation are found in the Misool chain, particularly in the SW complex of small islets and at the western end of the Misool mainland. Within the Waigeo group, extensive limestone habitats were explored near Aljoei (0°11'43S, 130°15'39E) and at Wayag (0°10'21N, 130°01'17E).

Many of the smaller limestone islands are undercut at the highwater line into toadstool platforms, or are sculpted into steep conical stacks (Fig. 26). Oftentimes the sides of the taller islands have dizzying vertical faces that plunge for hundreds of feet (Figs. 27, 28). On Wagmab, the stepped ledges have a stunted woody vegetation, frequently wind-sheared, comprised of *Stenocarpus moorei*, *Exocarpos latifolius*, *Polyscias* sp. nov., *Wikstroemia androsaemifolia*,

---

[2]The FIMS code is partly based on the dominance of *Gymnostoma papuanum* (=*Casuarina papuana*) which is replaced by *Gymnostoma rumphianum* (=*Casuarina rumphiana*) in the Raja Ampat. The second species is a relatively minor element in the limestone flora but a conspicuous emergent on ultrabasics. In conformity with FIMS convention, the Raja Ampat code would be rendered as 'HsCr', or 'HsGr' in any extension of the typing system to Western New Guinea.

FIG. 22. Misool. *Melaleuca leucadendron* s.l., the dominant stand-forming species in the Raja Ampat savannas. The whitish-papery outer bark and drooping leaves are characteristic. Photo November 10, 2002.

FIG. 27. Aljoei. Limestone cliffs. Labyrinthine submarine caves are present along many of the underwater walls. Photo November 14, 2002.

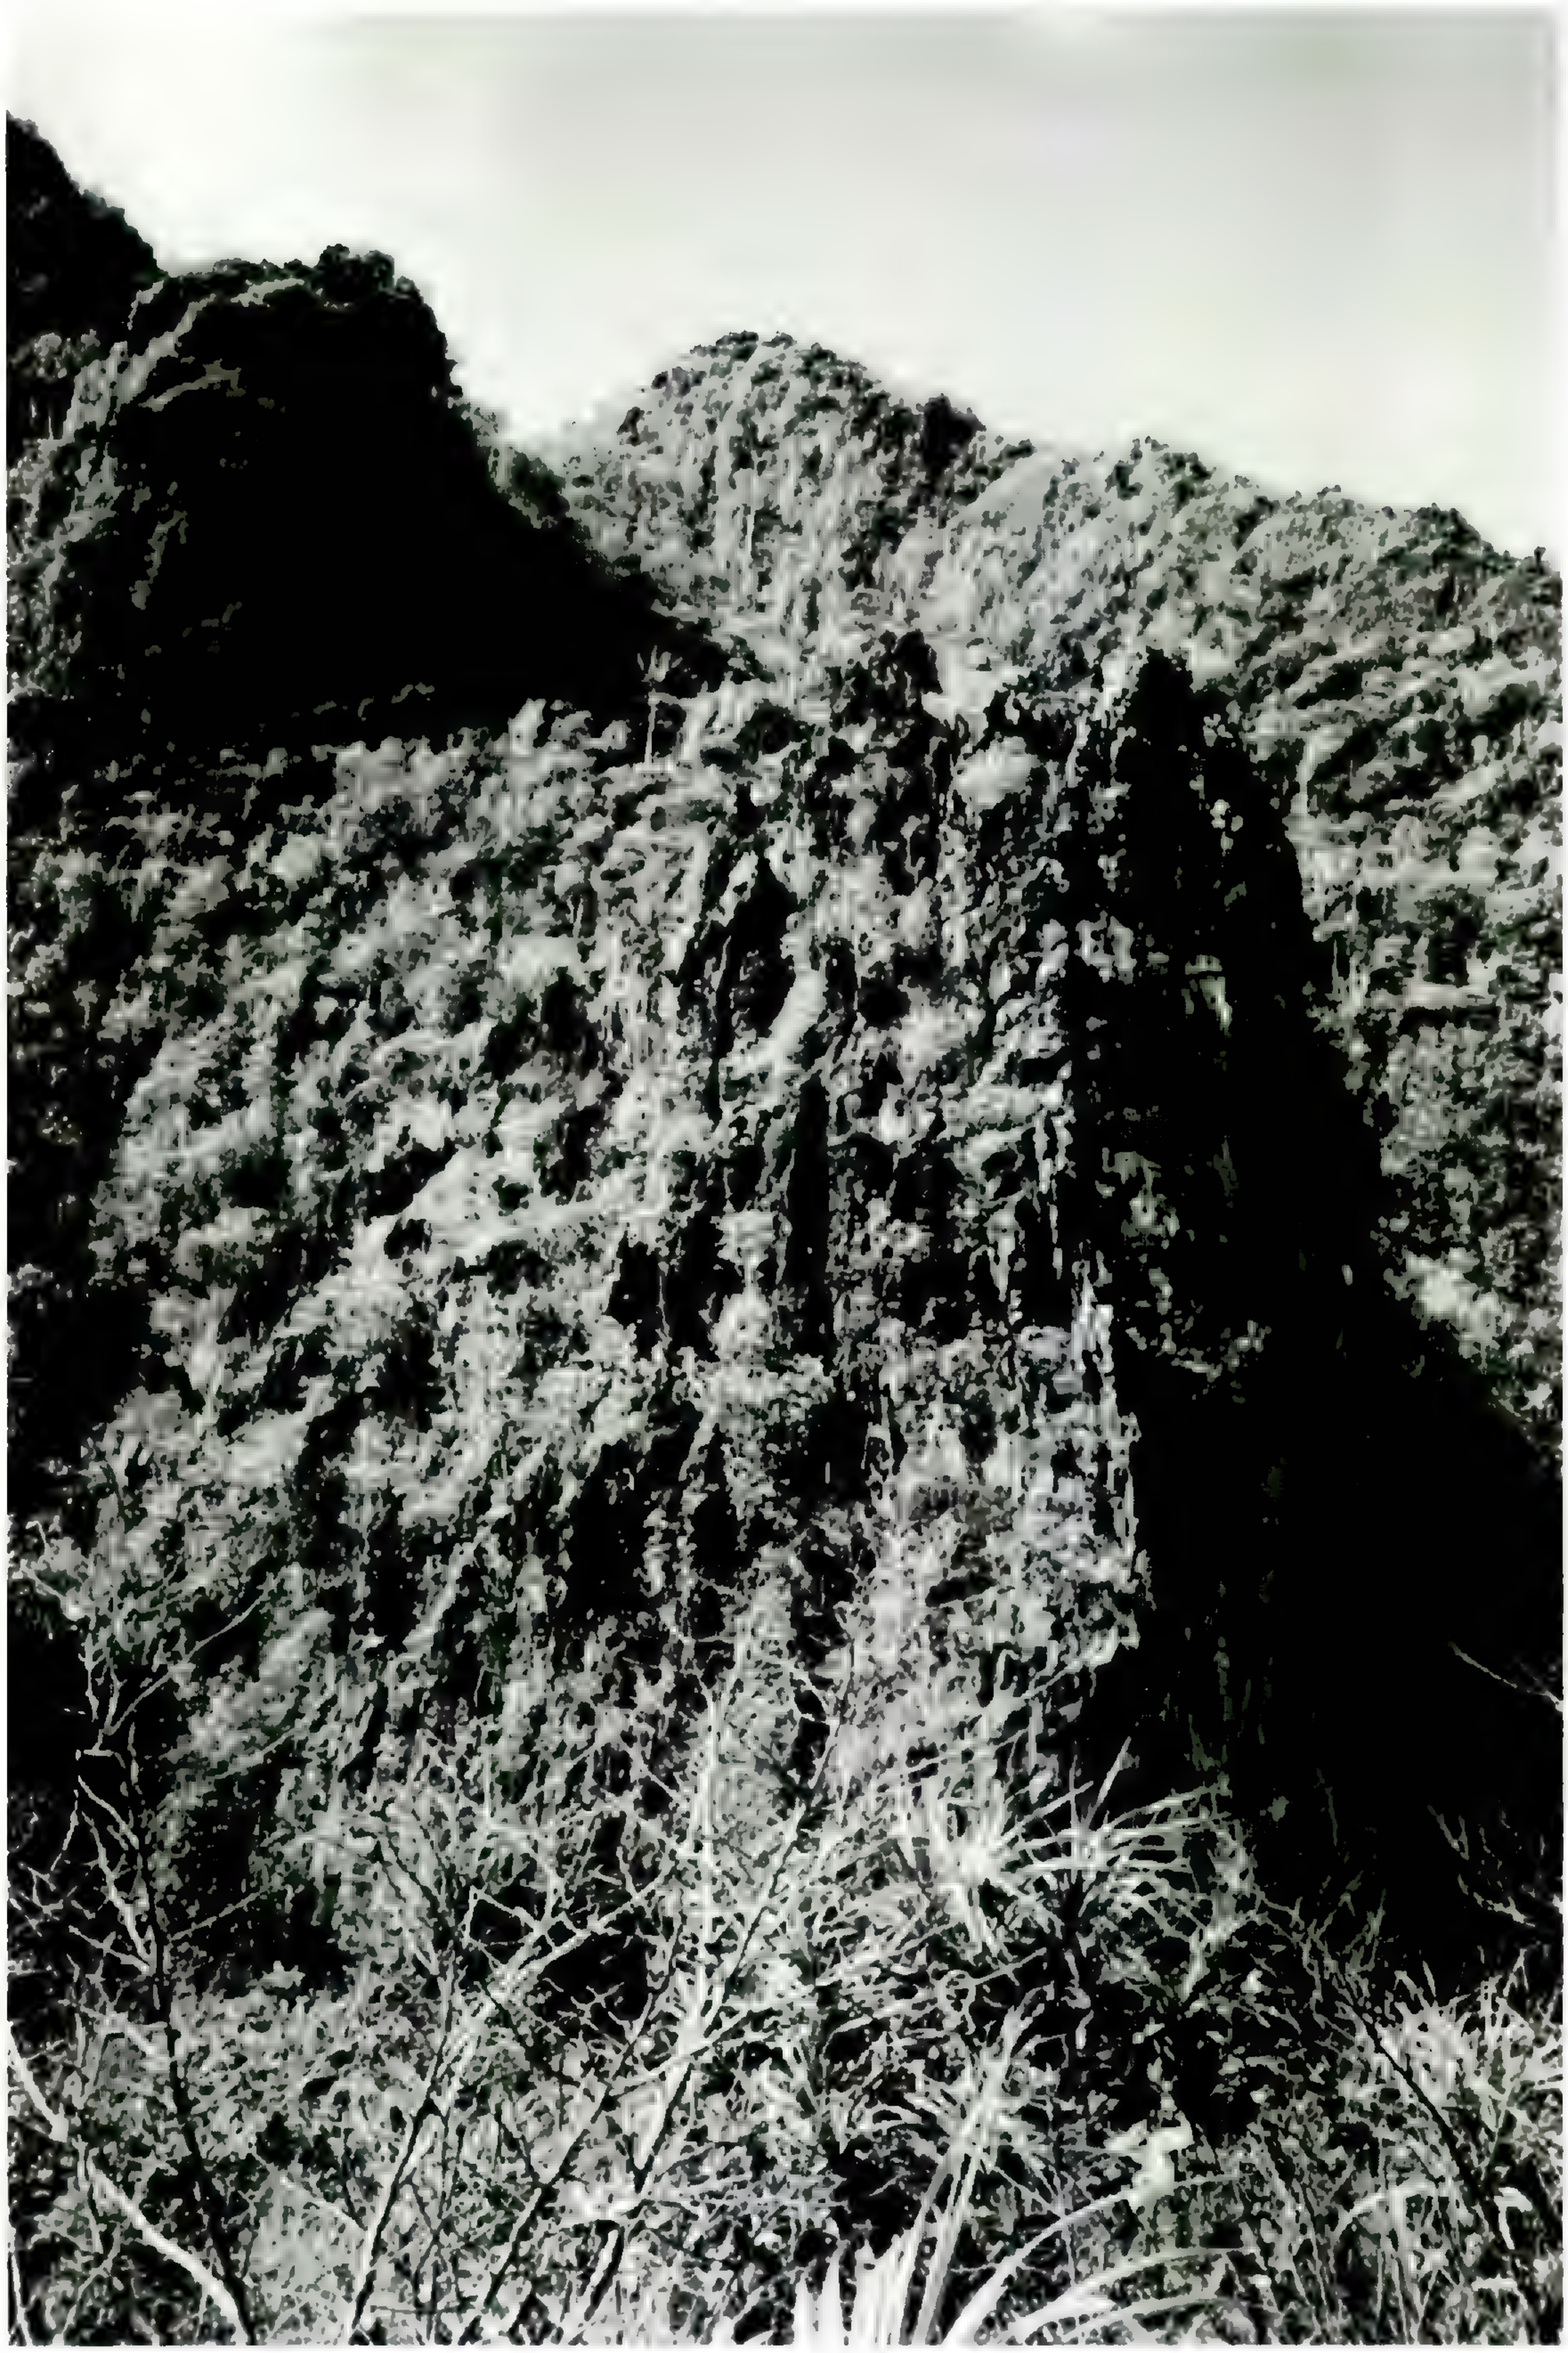

Fig. 28. Limestone precipices on Wagmab. Photo November 4, 2002.

Calophyllum spp. (including the *novoguineense* complex; cf. Stevens 1995), and many vines of *Alyxia purpureoclada* (Fig. 29). The unusual *Podocarpus polystachyus* is a dwarfed *krummholz* on solid rock, sprawling across ledges and barely ascending to 1 m height. But at Wayag, crestline populations of the same species grow as erect trees to 7 m height (Fig. 30; 0°10'25N, 130°01'22E and 0°10'42N, 130°01'16E).

On nearly all the limestone islands, *Gulubia costata* is a conspicuous emergent, often forming dense stands along the higher slopes and crestlines. *Barringtonia*, *Dracaena*, *Ficus*, *Garcinia*, *Gynotroches*, *Myrsine* (*Rapanea*), *Pouteria* (*Planchonella*), *Schefflera*, *Serianthes*, and *Sterculia* are also common subarborescent genera, but a disproportionate number of morphospecies were documented only by sterile or scrappy vouchers and cannot be identified with certainty. Of all the Raja Ampat habitats, the limestone vegetation was the most severely affected by the El Niño drought, and effective documentation of such communities was very difficult under the prevailing conditions. The canopies on most islands were brown and withered, though probably not dead. Limestone karst is undoubtedly a poor reservoir for soil moisture. Especially on small islands, stands with green foliage were often restricted to the colluvial accumulations in valleys and small draws (Figs. 11, 12).

Archidendron paluense, *Lunasia amara* var. *amara*, and the vinelike *Bauhinia binata* (*Lysiphyllum binatum*) were common taxa in karst understories of the western Raja Ampat, especially on platforms and stacks around Misool proper. At Mesemta Bajampop, substantial populations of *Rauvolfia moluccana* and *Monophyllaea* were also noted. The *Archidendron*, *Bauhinia*, *Monophyllaea*, and *Rauvolfia* were newly recorded for the district (cf. Burtt 1978; Verdcourt 1979; Nielsen et al. 1984; Hendrian & Middleton 1999). New registers for such common or conspicuous plants are indications of the undercollected status of the limestone, and show how poorly documented this flora still remains even after more than a century of Papuan exploration.

Lowland ultrabasic scrub and forest.—(W, HsCp) Renowned in scientific literature, the Raja Ampat serpentine flora is also one of the region's most picturesque environments. At Kawe (Figs. 31, 32) and Waigeo's north shore (Fig. 33) the ultrabasic scrub affords breathtaking panoramas of turquoise reefs and red laterite across extensive stretches of coastline.

The TNC survey explored the ultrabasic zone in a series of ascents along steep-sided buttress ridges. Most of the vegetation consisted of xeromorphic scrub or woodland with similar characteristics to communities described in an earlier account of the eastern Waigeo peninsula (Royen 1960).

During the first landfalls on Kawe (ending at 0°03'07S, 130°08'05E), the forest team found a distinctive woodland of *Ploiarium sessile*, *Exocarpos latifolius*, *Gymnostoma rumphianum*, *Decaspermum bracteatum*, *Ixonanthes reticulata*, and *Myrsine rawacensis* (Fig. 34). The spreading sympodial crowns of *Ploiarium*

Fig. 29. Wagmab. Vegetation on limestone ledges. Photo November 4, 2002.

sessile were a particularly striking characteristic of this community (Fig. 35). In the wide spaces between the larger trees were many shrubs of *Myrtella beccarii*, *Styphelia abnormis* and (in lesser numbers) *Dodonaea viscosa*. Vines of *Alyxia laurina* were common climbers and scramblers. Patches of *Dicranopteris linearis* blanketed the ground nearly everywhere, with *Dianella ensifolia*, *Nepenthes danseri*, *Palhinhaea cernua*, *Machaerina disticha*, and *M. glomerata* scattered mainly over the bare spaces. *Artocarpus*, *Livistona*, and *Vitex* were common on lower slopes and valley floors (Fig. 36; 0°03'05S, 130°08'24E).

On the Go Isthmus of Waigeo (Fofak Bay at 0°02'22S, 130°43'43E), the ultrabasics were similar though somewhat richer, and also included *Arytera littoralis*, a small-leaved *Gmelina*, *Melastoma malabathricum* ssp. *malabathricum*, *Psychotria tripedunculata* (Fig. 37), and *Rhodamnia novoguineensis* among the common woody plants. Parts of the scrubland above the bay had been burned, exposing large patches of the distinctive red laterite (Fig. 38). Within such areas, the early fire succession consisted of a sparse association of *Commersonia bartramia*, *Myrtella beccarii*, *Scaevola oppositifolia*, and *Styphelia abnormis*. Although the ridgetop habitats are generally of open aspect, the vegetation in the draws is a closed codominant forest of *Dillenia alata* and *Calophyllum* spp. At scattered places in the ultrabasic zone (on both crestlines and depressional areas), the scrub is replaced by a taller *Gymnostoma rumphianum*-Sapindaceous

FIG. 30. Wayag. *Podocarpus polystachyus* (5–7 m tall), a common limestone species. Photo November 16, 2002.

Fig. 31. East-central coastline of Kawe island, an ultrabasic outcrop 15 km west of Waigeo. In contrast to the uneven and deeply dissected limestone, ultrabasics are characteristically composed of massive ridges with uniform slopes (Löffler 1977). Photo November 18, 2002.

FIG. 32. Kawe. Three-shot montage (moving N to ESE: top frame to bottom frame) of ultrabasic woodland near the summit. The equator passes slightly to the right of the small island in the near background (center photo). Western Waigeo is on the horizon of the last frame (to ESE). Photo November 17, 2002.

Fig. 33. Waigeo ultrabasic scrub at the entrance of Fofak Bay. Center of view to the southeast, showing the irregular outline of limestone karst against the skyline (compare Fig. 31 Kawe island). Foreground: the sympodial architecture of *Ploiarium sessile* is the most distinctive feature of the open community. *Dicranopteris linearis* forms the groundlayer. Photo November 19, 2002.

FIG. 34. *Myrsine rawacensis* on Kawe ultrabasics. Photo November 17, 2002.

FIG. 35. *Ploiarium sessile*, the dominant woody plant in the ultrabasic scrub. Obtuse leaves and sessile flowers immediately distinguish this species from congeners (Kobuski 1950). Originally recorded from Halmahera (ibid.), *P. sessile* is still known from only a few collections. Photo November 17, 2002.

canopy with a *Myrtella beccarii* understory (e.g. at Kabare, 0°04'18S, 130°56'36E; Figs. 39, 40). Unlike the open growth, this taller community (at Kabare) is densely stocked with 7–10 m pole-trees including the serpentine indicator *Ploiarium sessile*. *Gymnostoma rumphianum* is a 25 m emergent in such situations. The ultrabasic vegetation is thus represented by several communities, collectively forming an intergrading series of facies ranging from bare 'blow-outs' (Fig. 41) through woodland of varying densities, then finally to a closed multistoried forest.

DISCUSSION

Raja Ampat plant communities are primarily lowland environments. There are no areas of significant size higher than the 900–1000 m level where montane conditions generally begin (cf. Paijmans 1975, 1976; Johns 1977; Grubb & Stevens 1985; Hammermaster & Saunders 1995a). Although Royen (1960) describes a mossy montane forest on Mt Buffelhoorn, such habitats could not be visited within the time allowed by the survey schedule. None of the daily excursions from the coast were able to penetrate beyond 500 m elevation.

Within the limitations imposed by rapid assessment, it is apparent that

FIG. 36. Serpentine bedrock in a large V-valley of south-central Kawe. In spite of the drought, a spring-fed creek flowed for several hundred meters over waterfalls in the middle valley, before disappearing into crevices along the streambed. A locally-luxuriant vegetation flourished along the banks, with dry woodland (Fig. 6) covering the higher slopes. No aquatic life was present other than small shrimp. Photo November 18, 2002.

Fig. 37. The aptly-named *Psychotria tripedunculata*, one of the most common shrubs on the ultrabasics. Photo November 19, 2002.

Fig. 38. Waigeo fire successional community. Burning removes the normal groundlayer of *Dicranopteris linearis* and *Machaerina glomerata*, leaving mainly scattered shrubs of *Commersonia bartramia*. Photo November 19, 2002.

Fig. 39. A closed stand of pole-stemmed trees near the fire succession shown in Fig. 38. The ultrabasic forest facies is connected to the open vegetation by a continuum of transitional communities. Photo November 19, 2002.

FIG. 40. Ultrabasic forest at Kabare. Showing the closed structure of the presumably older growth, often *Gymnostoma-Myrtella* codominant. Photo November 20, 2002.

FIG. 41. Waigeo blowout. Large patches of sheet-eroded earth are scattered through the scrubland, exposing the distinctive orange-red laterite of the ultrabasic zone. These erosional features are probably a recent result of forest removal. Although the open communities convey an impression of stability and continuity, the development of such areas is actually part of a historical pattern of ecological degradation. Photo November 19, 2002.

the Raja Ampat flora is depauperate and disharmonic relative to adjacent mainland environments and that these distinctions become more pronounced in the outer island groups (e.g. Misool and Waigeo). Many of the most characteristic Papuasian families, including Annonaceae, Elaeocarpaceae, Gesneriaceae, Lauraceae, Melastomataceae, Meliaceae, Piperaceae, and Urticaceae, were poorly represented in the lowland habitats where they are ordinarily prominent. Epiphytes and climbers were also generally scarce, as were several herbaceous families usually found in New Guinea forest understories (e.g. Marantaceae, Orchidaceae, Zingiberaceae).

This westward trend of diminishing diversity across the archipelago is correlated to a general reduction in rainfall and to the limiting nature of the western substrates. Rainfall is directly correlated with floristic diversity, more than with any other abiotic factor (Gentry 1988). The perception of highest richness in the near-mainland environments of Salawati and Batanta, and the impression of lower species counts toward the outer groups, is consistent with annual rainfalls (cf. Mangen 1993): Salawati and Batanta (3000–3500 mm); Misool (2500–3000 mm); Waigeo and adjacent islands (1500–2000 mm). The floristic trends expected from moisture availability are enhanced by the substrate dis-

FIG. 42. Kamiali, Papua New Guinea. Successional scrub community on a 15-year old landslide. Plants on the exposed ground include *Myrtella beccarii*, *Stenocarpus moorei*, *Dicranopteris linearis*, *Machaerina glomerata*, and *M. rubiginosa*. The dominance of Cyperaceae (particularly *Machaerina*) is a curious feature of the ground layer in situations where grasses would ordinarily dominate on conventional substrates. This same pattern occurs on Waigeo serpentine. Photo Feb. 5, 2003.

FIG. 43. Kamiali, Papua New Guinea. Serpentine woodland dominated by *Gymnostoma papuana*, *Weinmannia fraxinea*, and *Tristaniopsis macrosperma* in the canopy, and by *Dicranopteris linearis* and *Myrtella beccarii* in the understory. Kamiali has about twice the rainfall of Waigeo, resulting in a denser and more diverse vegetation. Many species are common to both districts. Photo October 6, 2002.

tinctions. Whereas most edaphic environments in the eastern islands are of mineralized soil, the outer islands are predominantly limestone or ultrabasics, infertile substrates that are known to be limiting for plant growth (Royen 1963; Kruckeberg 1985; Brooks 1987). The synergistic combination of factors results in diminished richness but increased endemism.

In terms of exploration priorities, the highest potential for taxonomic discovery is probably with the Misool karst. Waigeo ultrabasics are comparatively easy to access and the communities are usually of low stature and density, characteristics which favor collection saturation. Most, if not all, of the ultrabasic endemics have probably been discovered. In contrast, the Misool limestone is wetter (notwithstanding conditions during the survey), very difficult to traverse, and suitable collections are much harder to find. A significant number of unknown taxa is likely to be present on the karst. The new distributional records from the survey are suggestive of future opportunities.

Conservation Assets.—When judged on the basis of uniqueness, the ultrabasic and limestone vegetation are the highest-value communities in the Raja Ampat. As presently known, the ultrabasics have more species endemic to its habitats than any of the other communities. Plants restricted to Waigeo ser-

FIG. 44. Peninsula at mouth of Fofak Bay, Waigeo. Inland view to the north (opposite the perspective in Fig. 33). Mapped as a *Gymnostoma* (*Casuarina*) forest in 1955, this area is now an eroded and depauperate scrubland. A few relictual emergents of *Gymnostoma rumphiana* are visible in the far distance, apparently all which remains of the former forest. Photo November 19, 2002.

pentine include *Alstonia beatricis*, *Alyxia laurina*, *Archidendron royenii*, *Guioa waigeoensis*, and *Maesa rheophytica*. *Psychotria tripedunculata* is also known primarily from the ultrabasics, with only one record originating elsewhere.

Waigeo's floristic patterns can be understood by comparison with similar areas from other districts in New Guinea. In the Bowutu Mts of Morobe Province, an elevational sequence of ultrabasic landscapes forms one of the largest features of this type in Papuasia (i.e. the Papuan Ultrabasic Belt, cf. Thompson & Fisher 1965; Bain 1973; Löffler 1977). Especially within the Kamiali Wildlife Management Area (KWMA), the serpentine flora extends across a series of coastal communities beginning at sealevel, in a manner analogous to Waigeo.

KWMA habitats are subject to frequent landslides because of a local combination of humid climate and steep coastal ridges. In the recovery following landslides, the community that develops is a scrub composed primarily of *Myrtella beccarii*, *Dicranopteris linearis*, *Machaerina glomerata*, and *M. rubiginosa*; with (at lesser frequencies) *Stenocarpus moorei* and *Tristaniopsis macrosperma* (Fig. 42). In appearance and composition, the pioneer community is very similar to the Waigeo scrubland and also occurs alongside a series of taller forests including many of the same elements (Fig. 43). The KWMA

FIG. 45. Mesemta Bajampop. Scenic limestone forests adjoining a sheltered reef teeming with marine life. Some of the highest coral counts during the survey were recorded from this reef, e.g. from the blue hole in the right frame (Turak, pers. comm.). Photo November 5, 2002.

community variation clearly represents a successional sequence, which can be tracked because of the known history of specific sites.

Royen (1960: 41) described the Waigeo scrub as an edaphic climax, but its spatial proximity and structural resemblance to other communities suggest otherwise. By analogy to similar environments, most of the Waigeo ultrabasics are probably an early stage in a successional sequence caused by fire. The principal characteristics of the open scrub are hardly different from landslide seres of the KWMA, except that the Waigeo communities are much larger, extending continuously over hundreds of hectares. The distinction in spatial scale can be attributed to the presumed fire etiology, which would tend to act over much larger areas than landslides. The etiologies can themselves be explained by the climatic contrasts between the sites. Fires are a common ecological factor in dry environments like Waigeo, while humid localities (KWMA rainfalls are 4000 mm per annum) are naturally susceptible to landslides during periods of heavy rain. Royen's own observations provide evidence of instability in the Raja Ampat ultrabasic vegetation (Royen 1960). The ridge in the foreground of Figs. 33 and 41 was a *Gymnostoma* (=*Casuarina*) forest in 1955 (ibid.: Fig. 5). As documented by the TNC survey, that forest now remains only as relictual trees surrounded by scrubland (Fig. 44). These open areas are clearly a new development and not a permanent edaphically-induced feature.

The frequent occurrence of fires is currently reflected in the patchy distributions of ultrabasic forest on Waigeo, an expected pattern if seral sequences are being continuously reset over large areas. Although the serpentine scrubland is one of Papuasia's most impressive environments, the rare and endemic taxa are concentrated in the taller vegetation, and this latter habitat probably represents a more valuable conservation asset. In an environment with fire-induced succession, the closed forest (Figs. 39, 40) should be the richest community, and thus the more promising target for future exploration.

Apart from the biotic measures, aesthetic considerations are a legitimate part of any environmental evaluation. Waigeo and Misool landscapes are very photogenic, and can serve as focal assets for an ecotourism niche market in combination with the marine attractions, as already demonstrated by the *Pindito* (www.pindito.com).

Ecosystem Threats.—During the last 50 years, the areas of post-fire succession in northern Waigeo have expanded substantially (compare Royen 1960: Figs. 3, 5). Several endemic plants are probably being threatened by the existence of this historical trend, particularly by the accompanying reductions of taller communities. Among ultrabasic species, *Archidendron royenii*, *Alstonia beatricis*, and *Maesa rheophytica* are still known only from their types, taken in primary forest or older-growth woodland (see Nielsen et al. 1984; Sidiyasa 1998; Sleumer 1987). From the circumstances of their collection, these plants are probably associated with the advanced stages of the ultrabasic succession,

and their apparent rarity is consistent with habitat reduction caused by increased fire frequency. In contrast, the ultrabasic endemics *Guioa waigeoensis* and *Alyxia laurina* are known by several collections from the open areas, and are probably seral taxa (cf. Welzen 1989; Middleton 2000).

Naturalized alien plants were not found on serpentine, or on most of the isolated karst islands at Aljoei and Mesemta Bajampop. Although limestone areas near human settlements often have a few adventives (viz. *Bidens pilosa*, *Boerhavia erecta*, *Euphorbia heterophylla*, *E. hirta*, *Passiflora foetida*, *Stachytarpheta jamaicensis*, *Tridax procumbens* etc.) truly invasive taxa were absent. The noxious *Lantana camara* and *Piper aduncum* were recorded only on Batanta and Salawati. The same factors which make the western environments limiting for plant growth apparently act to discourage the establishment of aliens.

A planted patch of *Hibiscus rosa-sinensis* was seen at uninhabited Wagmab, and even if such occurrences are not threatening, deliberate introductions into otherwise weed-free habitats need to be discouraged by proactive conservation policy. Predictive guidelines for assessing possible invasive success of alien plants have been developed for other island environments (cf. Pheloung et al. 1999; Daehler & Denslow 2002). Their application should be considered by Papuan managers administering conservation tracts, as most communities in the western Raja Ampat are of entirely indigenous or endemic composition. Nowadays, in a world where the spread of aggressive species contributes to homogenization of floras, areas such as the Misool karst are an increasingly rare ecological resource.

Each of the principal islands (Batanta, Misool, Salawati, Waigeo) have sizable set-aside areas designated as nature preserves (Supriatna 1999). However existing logging threats are substantial, and commercial operations were filmed during the recent TNC assessment even within the so-called reserves. Although the archipelago is known to have significant plant and faunal assets, many of these are under threat and will require management action to ensure their continuity (ibid.). Establishing new incentives for conservation will not be easy, since in most Raja Ampat forests the emergent canopy is composed of major exportable timbers (*Intsia bijuga*, *I. palembanica*, *Pometia pinnata*, *Flindersia amboinensis*, *Vatica rassak*; see Louman & Nicholls 1995) occurring at stocking densities which favor profitable extraction (Departemen Pertanian Direktorat 1977). Although the current concessional areas are habitats with good site capacities for tree growth, the ultrabasics and limestone karst have stunted vegetation of little value as logging targets, and are thus at lesser economic risk.

Despite indications that climatic warming will cause substantial reductions in Papuasia's rainforest biome, there have been no attempts to define local planning and management responses to this threat. Baselines are much needed for determining the onset and direction of climate-induced change in a variety

of communities. Because of their insular and pristine status, many Raja Ampat environments would make appropriate stations for monitoring the floristic effects of El Niño oscillations. The western islands are part of a forest continuum spatially connected to perhumid mainland habitats, extending across a geographic sequence of sparsely inhabited landscape, tectonic, and biotic environments. The district is very suitable as a venue for ecological research.

Nearly all conservation programs in New Guinea are committed exclusively to terrestrial or marine habitats, due to the disparate value of such environments when they occur together at most sites. However at Misool and Waigeo, highly endemic forest communities lie alongside some of the most diverse reef ecosystems in the world (Fig. 45). This unusual combination of worldclass assets will permit development of holistic strategies for managing the linked land-sea resources. The information needs for integrated planning will be complex, requiring data inputs on wildlife, floristic, recreational, cultural-political, landscape, and human subsistence values. But owing to the unique nature of the environmental assets in this district, future initiatives have the opportunity of being cost-effective, innovative, and compelling.

APPENDIX OF BINOMIALS CITED IN THE TEXT

Aglaia argentea Bl. (Meliaceae)
Alstonia beatricis Sidiyasa (Apocynaceae)

ACKNOWLEDGMENTS

I thank The Nature Conservancy of Indonesia, Herbarium Bogoriense, the Arnold Arboretum, and Harvard Herbaria, for their institutional support of the Raja Ampat survey.

I also acknowledge Duncan Neville (TNC, land team coordinator), Johanis Mogea (Herbarium Bogoriense), Fery Liuw (Departemen Kehutanan Papua), Martin Hardiono (World Wildlife Fund Indonesia), and Victor Motombri (BP Indonesia) for their contributions to the floristic work. Rod Salm (TNC) was the overall expedition leader. Hitofumi Abe (Ecosystem Research Group, University of Western Australia) wrote the Japanese translation. Martin Hardiono provided the map template for Fig. 2.

The other expedition participants included Pawel Achtel (Jungle Run Productions, photographer), Gerald Allen (Western Australian Museum), Ryan Donnelly (environmental journalist), Fredy Frommenwiler (*Pindito* captain), Morgan Gabereau (Jungle Run Productions, producer and co-director), Creusa Thetha Hitipeuw (World Wildlife Fund Sahul), Djuna Ivereigh (Project Bird Watch), Agus Sumule (Universitas Negeri Papua), Yulianus Thebu (World Wildlife Fund Sahul), Emre Turak (Australian Institute for Marine Science), and Joe Yaggi (Jungle Run Productions, team leader).

ABSTRACT

The distinctive historical vegetation pattern of alternating tallgrass prairies on clay soils and oak woodlands/savannas on sandy soils in North Central Texas and East Texas has been described for more than a century. Many authors have attributed this pattern to relatively high levels of soil moisture available for tree growth on areas of sandy soil, and conversely, inadequate levels of soil moisture for tree growth on clay soils. However, this explanation is not consistent with present day observations of rapid invasion of clay soils by woody vegetation. We propose an alternative hypothesis, that the historical distribution of prairies and woodlands in North Central and East Texas can be explained by soil-dependent variations in grass biomass and resulting differences in fire frequency and intensity.

RESUMEN

El patrón histórico de vegetación en el que alternan praderas con hierbas altas en suelos calcáreos y robledales /sabana en suelos arenosos en el centro-norte y este de Texas ha sido descrito durante más de un siglo. Muchos autores han atribuido este patrón a los niveles relativamente altos de humedad en el suelo disponible para el crecimiento de los árboles en áreas de suelo arenoso, y por el contrario, niveles inadecuados de humedad en el suelo para el crecimiento de árboles en suelos calcáreos. Sin embargo, esta explicación no es consistente con las observaciones actuales de invasión rápida de suelos calcáreos por vegetación arbórea. Proponemos una hipótesis alternativa, que la distribución histórica de las praderas y bosques en el centro norte y este de Texas puede ser explicada por las variaciones dependientes del suelo en la biomasa de las gramíneas y las diferencias resultantes en la frecuencia e intensidad del fuego.

INTRODUCTION

Conditions at the time of European Settlement, Approximately 1800 A.D.

The vegetation of North Central and East Texas at the time of European settlement (hereafter referred to as presettlement vegetation) was characterized by well-defined zones of tallgrass prairie and oak woodlands/savannas (Fig. 1).

SIDA 20(3): 1139–1153. 2003

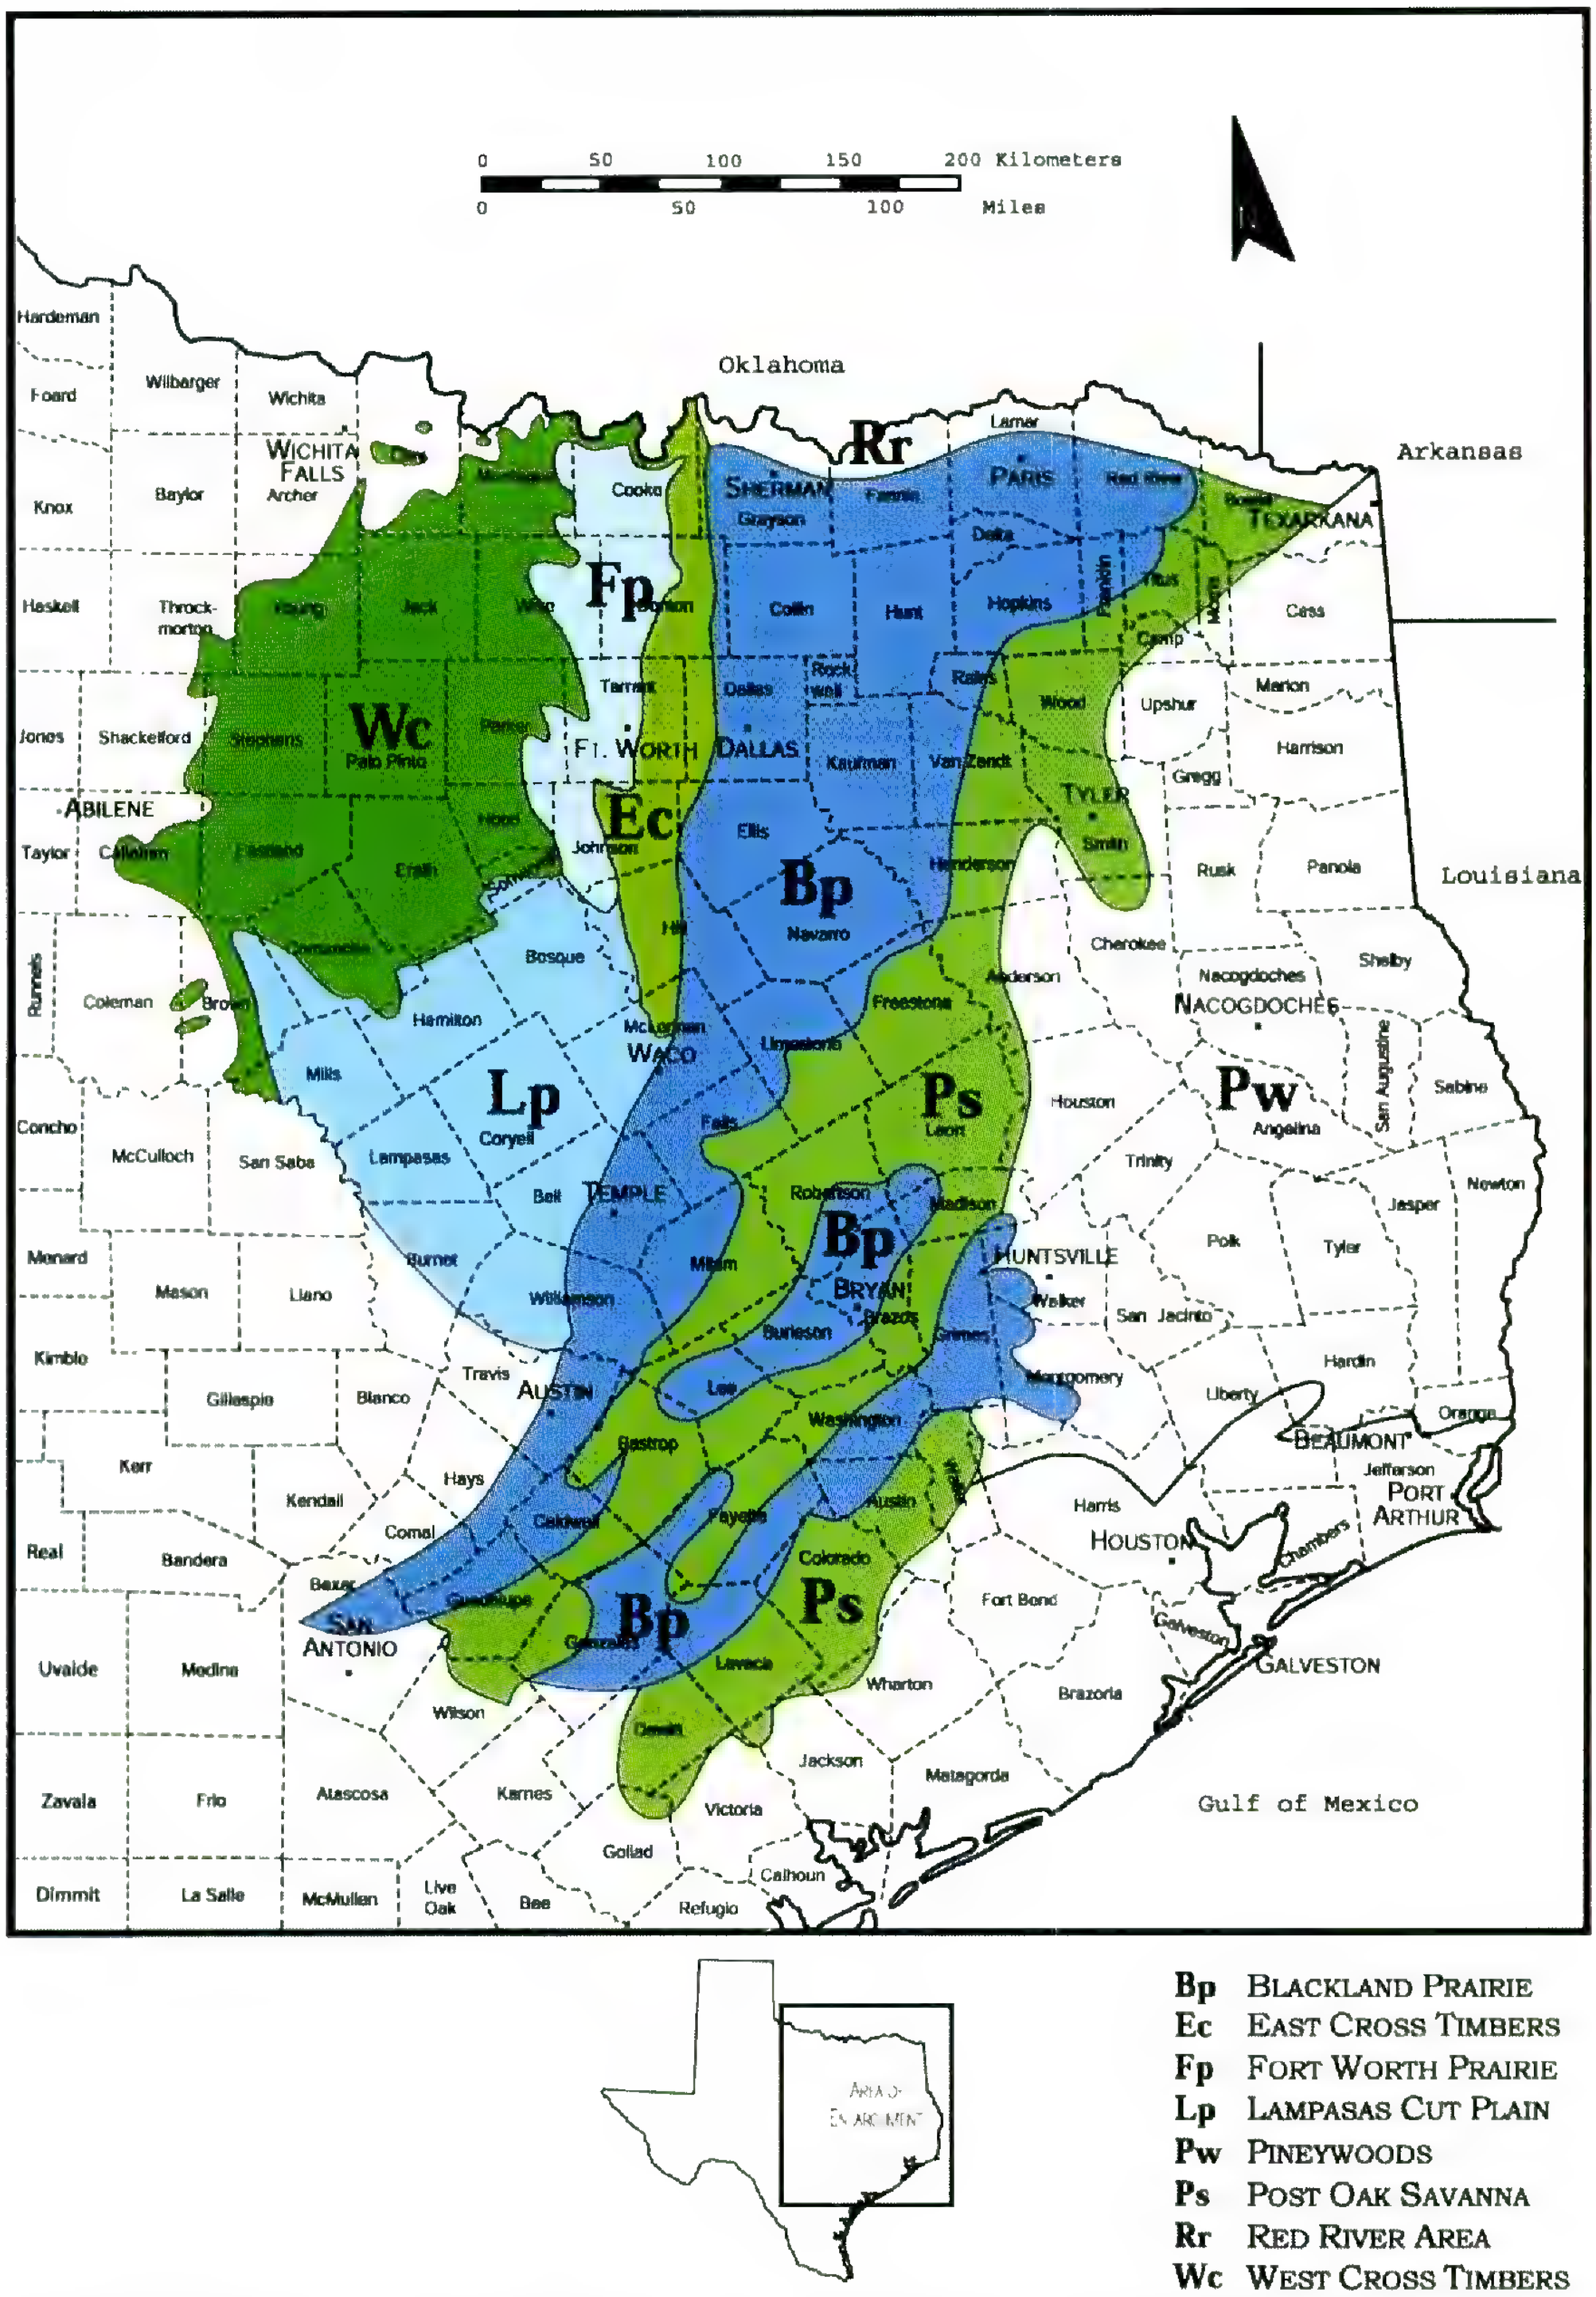

FIG. 1. Vegetational areas of North Central and East Texas. The Prairies are in shades of blue while the Woodlands/Savannas are in shades of green. Two vegetational areas of North Central and East Texas are not shown in color—the Pineywoods (forest) and the Red River Area (somewhat transitional between the Pineywoods and the Post Oak Savanna).

From west to east, the prairie bands are the Grand Prairie (composed of the Fort Worth Prairie and the Lampasas Cut Plain), the main belt of the Blackland Prairie, the San Antonio Prairie, and the Fayette Prairie, whereas the oak woodland/savanna belts are the West Cross Timbers, the East Cross Timbers, and three bands of Post Oak Savanna. These were highly recognizable areas of vegetation, with the Cross Timbers appearing on the earliest maps and the presettlement prairies described by numerous explorers, early settlers, and researchers as almost devoid of trees (e.g. Gregg 1844; Brooke 1849; Parker 1856; Dyksterhuis 1946; Thomas 1962; Correll & Johnston 1970; Hatch et al. 1990; Diggs et al. 1999; Telfair 1999; Francaviglia 2000). Hereafter we refer to these two vegetation types as Prairies and Woodlands. The current climate of the region, presumably relatively unchanged since presettlement times, is characterized by wet springs, dry summers with occasional thunderstorms, moderate to strong winds, and periodic multi-year droughts. As in many areas of central North America, prairie fires were common prior to settlement (Stewart 1951; Komarek 1965, 1966; Wells 1970; Wright and Bailey 1982; Collins & Wallace 1990; Bragg 1995). The relative frequency of ignition by lightning versus Native Americans is unclear.

The Woodlands represent the westernmost extension of the eastern deciduous forest. In general, the vegetation was composed of an oak overstory with tall grasses. The grasses were dominated by *Schizachyrium scoparium* (little bluestem), with *Andropogon gerardii* (big bluestem) and *Sorghastrum nutans* (Indian grass) as lesser dominants. While varying locally, the woody vegetation was in general dominated by two trees, *Quercus stellata* (post oak) and *Quercus marilandica* (blackjack oak). The tree density of the oak woodlands was variable, ranging from quite open to dense thickets. Some early accounts described woodlands through which wagons could easily pass (e.g. Marcy 1853, 1866), while others described almost impenetrable thickets (e.g. Kendall 1845). Gregg (1844) observed a variety of tree densities, noting that, "Most of the timber appears to be kept small by the continual inroads of the 'burning prairies;' for, being killed almost annually, it is constantly replaced by scions of undergrowth; so that it becomes more and more dense every reproduction. In some places, however, the oaks are of considerable size, and able to withstand the conflagrations."

The presettlement Prairies were vast grasslands dominated by *Schizachyrium scoparium* (little bluestem), with *Andropogon gerardii* (big bluestem) and *Sorghastrum nutans* (Indian grass) as lesser dominants, and woody vegetation generally limited to areas along the larger watercourses, as scattered mottes, or associated with locations that were protected from fire, such as mesas and buttes (Smythe 1852; Parker 1856; Hill 1901; Diggs et al. 1999). For example, Hill (1887) described the Grand Prairie as "a prairie region, utterly destitute of timber" and Kendall (1845) wrote, also of the Grand Prairie, "As far as the eye could reach ... , nothing could be seen but a succession of smooth,

gently-undulating prairies." Early accounts of the Blackland Prairie were similar. Smythe (1852) described the eastern edge of the Blackland Prairie as having "... a view of almost boundless Prairie stretching to the north, as far as the eye could reach. ..." and further, as "nearly destitute of trees."

Soils of North Central and East Texas

Most soils of the Prairies of North Central and East Texas are derived from lime-rich Upper Cretaceous rocks which weather to form soils with substantial levels of clay. Outlying segments of the Blackland Prairie (Fayette and San Antonio prairies) have soils developed from younger Tertiary age deposits. While the majority of Tertiary deposits in East Texas are sandy in nature (i.e., those supporting the Pineywoods and Post Oak Savanna), those underlying Prairie (e.g., Fleming, Oakville Sandstone, and Cook Mountain formations) in general have a relatively high clay content and in some cases develop soils which display the gilgai microtopography so typical of certain high clay soils (Launchbaugh 1955; Smeins & Diamond 1983; Miller & Smeins 1988). Further, where clay lenses are found in other geologic strata outcropping in isolated pockets of the Cross Timbers, Post Oak Savanna, and Pineywoods, areas of prairie vegetation can again be found (Dyksterhuis 1948; Hill 1991). It is thus clay that appears crucial in the development and maintenance of the grassland vegetation characteristic of the Prairies. In some cases clay is abundant throughout all soil horizons, while in others there is a clay-loam or loam surface layer—all the Prairie soils, however, have significant amounts of clay (Godfrey et al. 1973; Diamond & Smeins 1985). Conversely, the Woodlands are developed in general from Cretaceous and Tertiary sandstone rocks of such geologic layers as the Antlers/Trinity, Woodbine, Carrizo, and Wilcox, and can be generally described as sandy (Sellards et al. 1932; Hartmann & Scranton 1992).

Prevailing Explanation for the Distribution of Prairies and Woodlands

As discussed above, the presettlement distribution of the Prairies corresponds to the distribution of limestone parent material overlain by alkaline soils with a high clay content, while the presettlement Woodlands occurred on either sandy, slightly acidic soils or, in the westernmost part of the region, on gravelly and rocky substrates (Sellards et al. 1932; Dyksterhuis 1948; Diggs et al. 1999). The striking correspondence of vegetation and soil types led early writers to propose that the distribution of Prairies and Woodlands was due to the different water holding capacities of clays and sands. While the basic hypothesis has been stated many ways, its essence is that greater infiltration and water storage at depth in sandy soils permits tree survival, while clay soils do not support trees because of inadequate infiltration of water (and reduced root penetration) due to the clay's relative impermeability.

Hill (1887) appears to have been the first to propose this hypothesis. He argued that,

> "The reason why the timber confines itself to [the sandy soils is that they] ... afford a suitable matrix for the penetration of the roots of trees, and a constant reservoir for moisture, thus furnishing two of the greatest essentials to forest growth. ... The barrenness of the prairies, so far as forest growth is concerned, is owing to the absence of the requisite structural conditions for preservation of moisture, as well as the excess of carbonate of lime in their soils."

Subsequent authors reiterated Hill's contention. For example, Tharp (1926) suggested that the sandy soils increased available soil moisture for tree growth. Weaver and Clements (1938) argued that, "... the oaks ... have been able to maintain themselves against the competition of the grasses by virtue of the favorable chresard of the sandy soil." Dyksterhuis (1948) summarized much of this information, and apparently agreed with the general idea of sandy soil-moisture availability favoring the growth of trees. Allred and Mitchell (1955) reiterated these ideas:

> "Sandy, gravelly and rocky areas ... also improve local soil-moisture conditions in the grassland formation. Rainfall intake is high on these soils, which also yield up moisture to plants more readily and more completely than do heavier soils. ... In these areas, soil-moisture conditions have been improved sufficiently over the climatic normal so that trees or shrubs, particularly oaks, form savannah with the understory composed of grassland dominants of the True Prairie."

This reasonably intuitive explanation for the historic distribution of the Prairies and Woodlands has been nearly universally accepted, including by recent authors (e.g., Diggs et al. 1999; Francaviglia 2000).

However, the hypothesis that the Woodlands are restricted to sandy soils because of inadequate moisture availability on clay soils cannot be correct because, in fact, trees occur extensively on the clay soils. As noted above, early accounts noted woody vegetation along the larger watercourses and as isolated mottes or clumps of trees in scattered locations on the clay soils of the Prairies. More impressive, however is the current invasion of trees onto extensive upland areas of clay soil that can be widely observed throughout the Prairies (e.g., Launchbaugh 1955; Smeins & Diamond 1986). Indeed, the few remaining prairie remnants require active management to prevent loss to invading woody vegetation (Smeins & Diamond 1986). In the absence of fire, mowing, or some other suitable disturbance, trees such as *Juniperus virginiana* (eastern red cedar), *Gleditsia triacanthos* (honey-locust), *Celtis laevigata* (hackberry), *Maclura pomifera* (bois-d'arc), *Prosopis glandulosa* (mesquite), and *Ulmus crassifolia* (cedar elm) rapidly invade the native prairie and cause the vegetation to convert to a thicket and then a woodland/forest. A glance from the road along almost any major highway on the present day Blackland Prairie provides abundant evidence of rapid invasion by woody species in the absence of disturbance (Fig. 2). In areas no longer cultivated or otherwise disturbed, the invasion by trees can be observed within a relatively few years—this is particularly obvious in the numerous areas that were cultivated until relatively recently. It therefore seems clear that there is sufficient moisture for tree growth on the clay soils and

Fig. 2. Area of Blackland Prairie in Grayson County showing invasion by woody vegetation under current fire supression conditions (photo by W. Cole Weatherby)

some other mechanism or mechanisms must have been responsible for the historical difference in the vegetation on the clay Prairies and sandy Woodlands.

It should be noted that the woody species present on the modern day Prairies and Woodlands are largely different, probably due to the different soil requirements of the various species, and we do not view woody plant encroachment on the Prairies as simply an expansion of the Woodlands. Nonetheless, woody vegetation is now extensive on many formerly Prairie areas. The woody species currently encroaching on areas of Prairie vegetation were probably not in general major components of the adjacent presettlement Woodland vegetation. Rather, they are probably species that in presettlement times were present in low numbers on the Prairies themselves near streams or where topography made fire unlikely. On the other hand, some species (e.g., *Juniperus ashei*, *J. virginiana*) are at present highly invasive on both the Prairies and Woodlands.

HYPOTHESIS

Soil-dependent fire frequency

We propose that the presettlement distribution of Prairies and Woodlands in North Central and East Texas was not due to insufficient moisture for tree growth on clay soils, but rather to differences in fire frequency on different soil

types. We hypothesize that higher fuel quantity on clay soils increased the frequency and intensity of fire, and that fire in turn suppressed the growth of trees. Prairie fires are fueled primarily by grasses, as opposed to forbs or woody vegetation, so an increase in grass biomass leads to an increase in the quantity of fuel. We predict that grass biomass is typically higher on clay than on sandy soils due to better moisture and nutrient availability at the shallower rooting depth of grasses versus woody plants.

This situation would represent two alternative positive feedbacks. High fuel quantity on clay would encourage fire, which would suppress woody vegetation and under certain conditions (e.g., depending on season of burn—Howe 1995) stimulate subsequent grass growth (by removing dead biomass which hinders new growth), thereby maintaining high fuel quantity. Low fuel quantity on sand would reduce the chance of fire, which would foster invasion by trees that would then further suppress grass biomass (e.g., by shading or other competition) and the subsequent frequency and intensity of fire. These alternative feedbacks would lead to alternative stable states, Prairies and Woodlands (Fig. 3). This particular hypothesis for the distribution of Prairies and Woodlands is consistent with the more general conclusions of Scholes and Archer's (1997) review of tree-grass interactions around the world. They write that "Moist fertile environments [e.g. our Prairies] support a vigorous grass growth that, if not grazed, leads to frequent intense fires.... Semi-arid environments on sandy, low fertility soils [e.g. our Woodlands] are seldom treeless."

Soil type (and its effects on grass biomass) is not the only variable that affects the frequency or intensity of fire. Whether a fire ignites, how hot it burns, and its ability to spread also depend on a number of other variables including frequency of ignition events, season of year, rainfall, humidity, wind speed, topography, and grazing (some of which also affect grass biomass). These variables would combine in a stochastic manner to increase or decrease the frequency and/or intensity of fire in any given location at any particular time. For example, fire frequency and intensity would be low during a wet summer, but the resulting grass growth could combine with a subsequent windy drought to increase fire likelihood and intensity the following year. Thus, the systematic effect of soil type on fire would be increased or decreased at any given location at any particular time by the net effect of these other variables, with the result being substantial variation in the time since the last fire in different areas of both the Prairies and the Woodlands. When this stochastic variation is taken into account, the fire-frequency hypothesis can explain not only (1) the historical distribution of Prairies and Woodlands, but also: (2) the historically dominant tree species of the Woodlands; (3) the historical occurrence of isolated groves of trees on clay soils; (4) the present invasion of Prairies by trees; and (5) the difference between the historically dominant tree species of the Woodlands and the species that are increasing in abundance on the Woodlands and invading the Prairies today (e.g., *Juniperus* species).

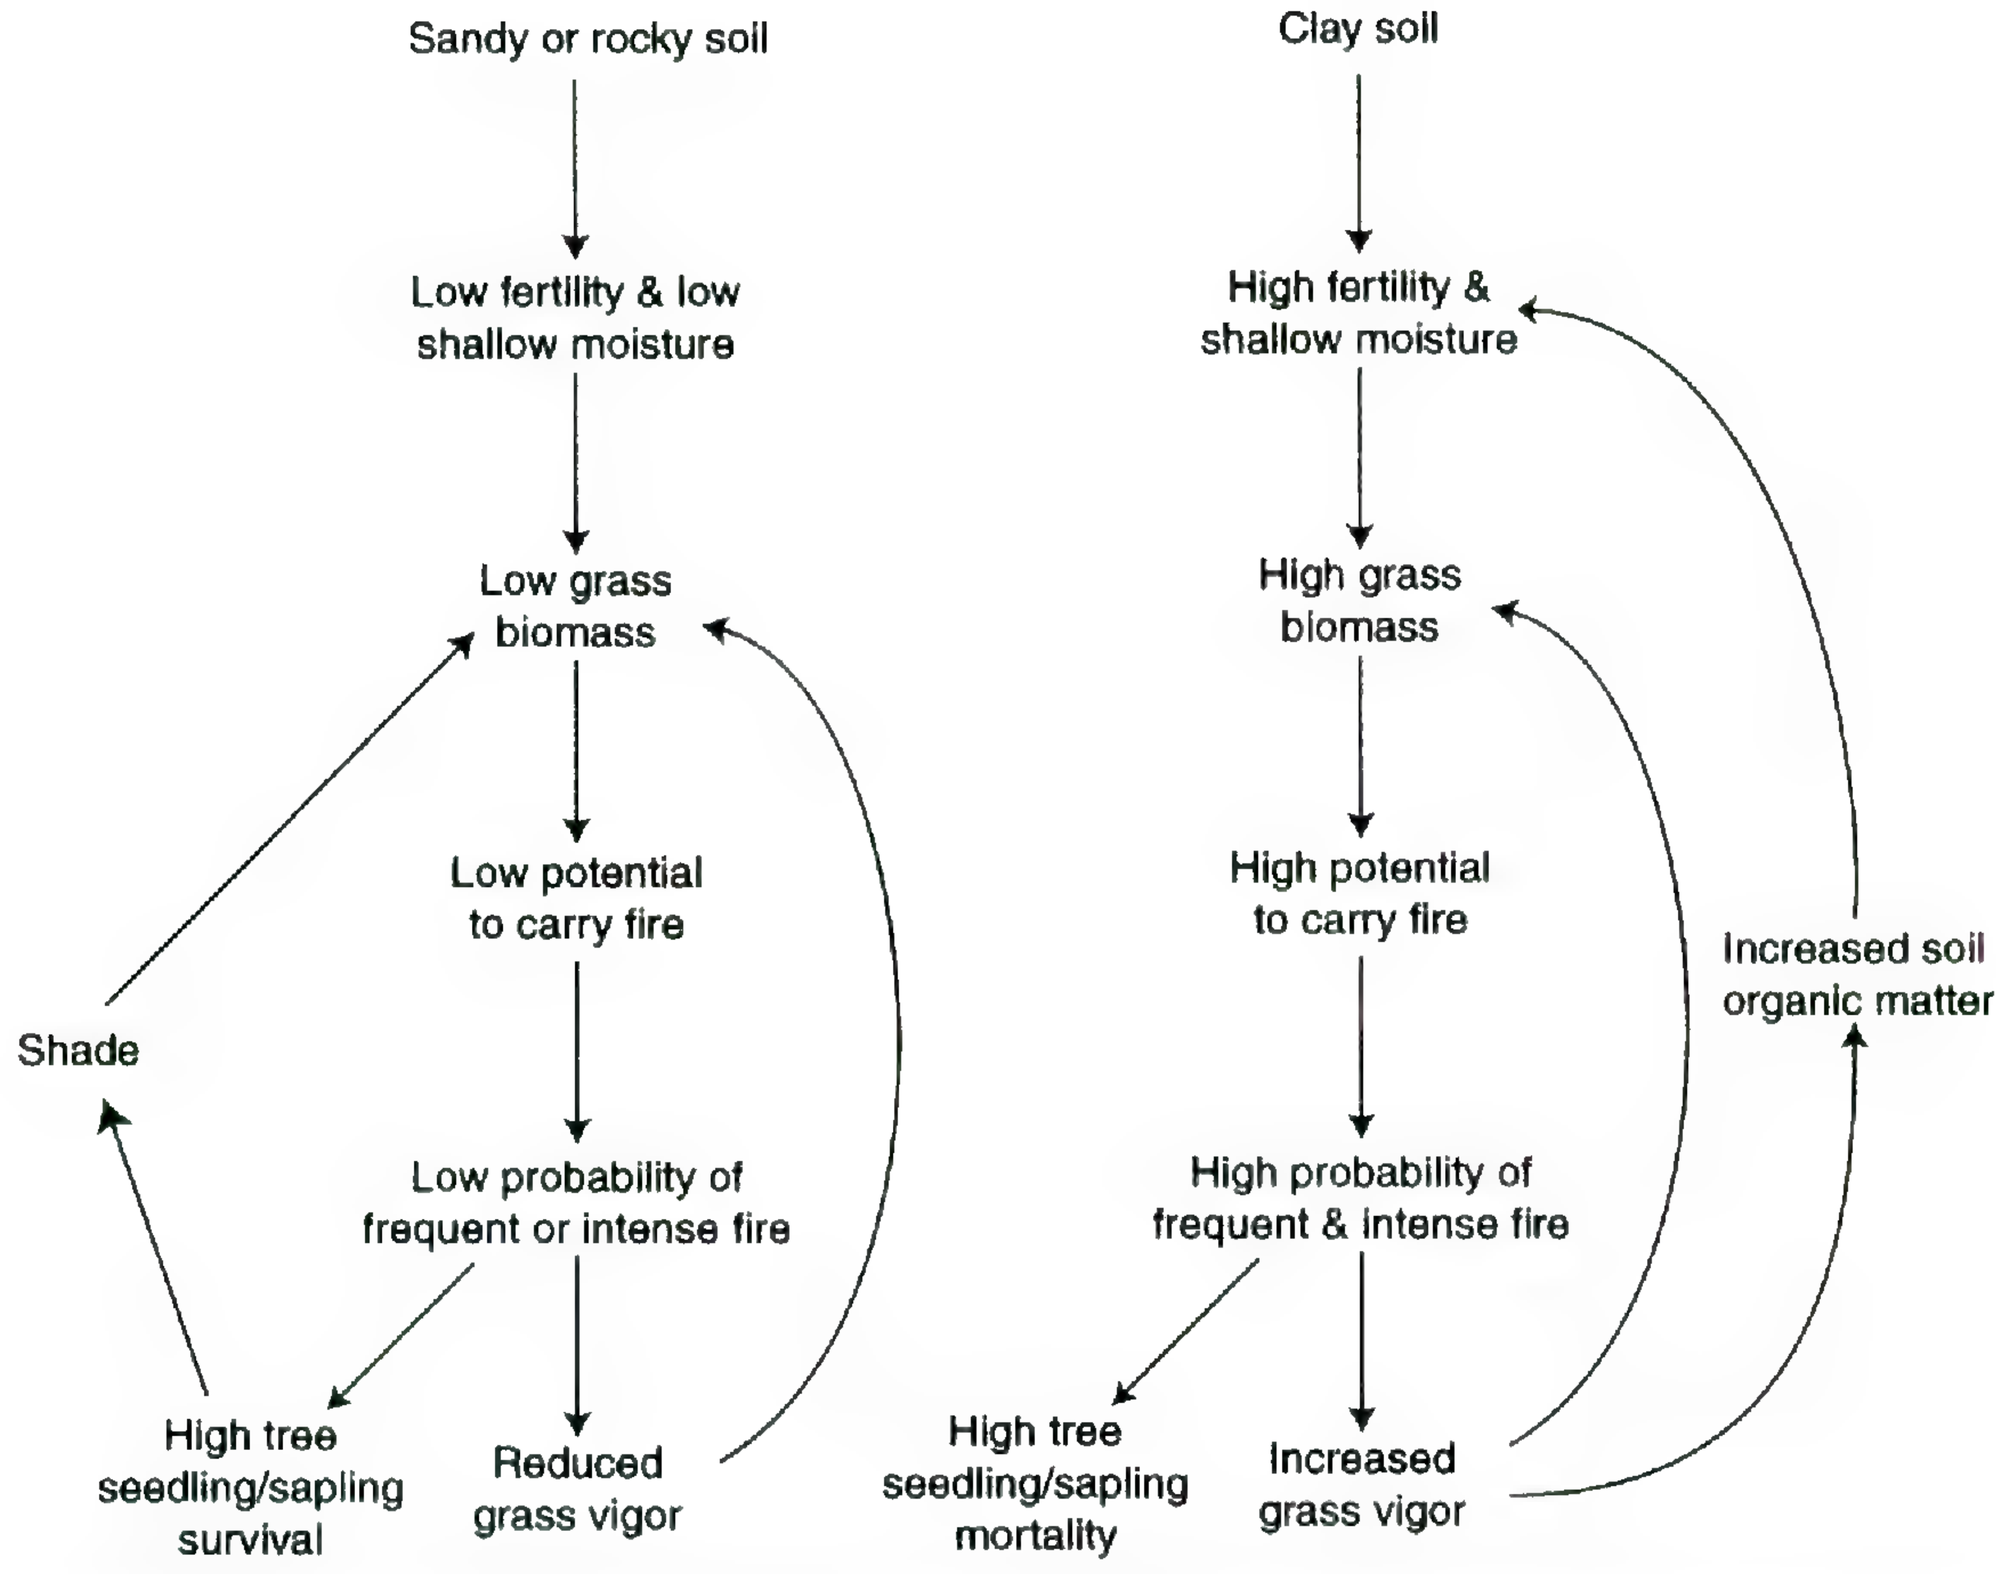

FIG. 3. Flow diagram showing two positive feedback routes to two alternative stable states.

The Woodlands were historically dominated by oaks, species with thick bark, stubby branches, and the ability to resprout from roots, features that impart resilience to grass fires. Further, occasional extended periods without fire on the Prairies would have allowed the establishment of the isolated groves of trees that were observed by Western settlers. Once established, such groves would have been unlikely to burn due to the suppression of grass growth by the trees and the resistance of large trees to fire.

The present invasion of the Prairies by trees can be explained by a lack of fire that has resulted from intentional fire suppression plus numerous and extensive fire breaks that have been created by human activities (roads, cultivated fields, overgrazed areas). Moreover, once this process begins, any Prairie area that becomes substantially invaded by trees would lose grass biomass and come to serve as an additional firebreak, thereby further reducing the likelihood of fire on adjacent remaining prairies. Finally, the present tree invasion of many (but certainly not all) areas of the Prairies (and of the Woodlands understory) is dominated by *Juniperus virginiana* (eastern red cedar) and *Juniperus ashei* (Ashe's juniper), species that are sensitive to fire (easily scorched/ignited and unable to resprout from roots).

The key assumption of our hypothesis is that the difference in grass biomass was sufficiently higher on the Prairies than the Woodlands to raise the likelihood, frequency, and intensity of fire on the clay soils of the Prairies compared to the sandy or rocky soils of the Woodlands. In addition, our hypothesis leads to the prediction that patches of open grassland on sandy soil are very rare except in instances of active management (e.g., suppression of woody species) or immediate proximity to clay soils (which would result in more frequent fires due to closeness to the fire-prone prairie vegetation).

We have not measured grass biomass on intact remnants of the Prairies and Woodlands, and therefore do not have the data necessary to estimate differences in a number of variables associated with fire (e.g., frequency, intensity, extent, pattern, season, etc.). Further, while some biomass and fuel loading data are available in the literature (e.g., Johnson & Risser 1974; Engle & Stritzke 1995), we have been unable to find directly comparable data for the area of study. However, substantial indirect evidence is consistent with the assumption of higher grass biomass on clay soils. First, during dry periods clay soils generally hold more water at grass rooting depths than do sandy soils. This is due to the relatively large surface areas of the individual clay particles and the large number of very small pores which act as billions of capillary tubes collectively holding large amounts of water (Vankat 1979). The result of this increased water holding capacity is that plants rooted in such soils may continue active growth much later in the dry season than plants rooted in coarser soils (Daubenmire 1974; Burgess 1995; McAuliffe 1995; Tucker 1999; Greeves et al. 2000; Ball 2001). Furthermore, undisturbed Blackland soils form gilgai, microtopographical surface features that function like shallow basins, increasing water retention during heavy rains (Hayward & Yelderman 1991; Diamond & Smeins 1993). Early settler accounts and observations of existing prairie remnants (e.g., the Nature Conservancy's Clymer Meadow preserve in Hunt County, the Matthews-Cartwright-Roberts Prairie in Kaufman County, and Austin College's Garnett Prairie in Grayson County) suggest that these "hog wallows," (as they were known to early settlers) were abundant on Vertisols of the presettlement Blackland Prairie. Temporary water storage in gilgai depressions of one-half acre foot of water per acre of flat prairie have been estimated. As much as six inches of rain could be temporarily trapped in these structures before runoff began (Hayward & Yelderman 1991). Meanwhile, the high surface area and negative surface charges of clay particles give clay soils high cation exchange capacity. This allows these soils to hold more ionized minerals or nutrients, including those essential for plant growth (Foth 1990; Whitehead 2000; Harpstead et al. 2001; O'Connell 2001). It is therefore not surprising that indirect evidence, such as agricultural productivity, suggests that the Blackland clay soils were among the most fertile soils west of the Mississippi River (Haywood & Yelderman 1991). In addition, the high below-ground biomass of Prairie vegetation serves to con-

tinually add organic matter to the soil, thereby functioning as a positive feedback mechanism to increase fertility and water holding capacity (in part due to the surface area provided by the additional organic material). Conversely, sandy soils have larger pores that allow water to drain more easily. They not only dry earlier during dry periods but "the more water that percolates through the soil, the more nutrients are washed out—particularly nitrogen, potassium and sulfur" (Tucker 1999). Therefore, soils that are high in sand, like those of the Woodlands, are often poor for plant growth since they are relatively infertile and often too well-drained (Vankat 1979).

Confounding factors

Several other factors have the potential to operate synergistically or in opposition to the soil-mediated fire frequency hypothesis in influencing the balance between grass-dominated and woody vegetation. Of particular importance is the grazing regime. Van Auken (2000), for example, has identified high levels of herbivory by domestic animals as the primary cause of brush encroachment in the semiarid grasslands of the southwestern U.S. This influence is probably the result of a combination of disturbance and reduced fire frequency. The grazing regime during presettlement times was certainly very different than at present. Instead of domestic animals continuously confined to limited areas of pasture, the primary herbivores were large dense herds of migratory bison free to move over vast distances. The grazing regime would thus have been extremely irregular both temporally and spatially. While a large herd could move through an area of Blackland Prairie and crop the vegetation very short (thus preventing fires), in some seasons or years a given area would probably be missed entirely leaving large amounts of standing biomass (heavy fuel load for fires). Under such conditions fire would not be expected every year, nor would it be essential every year for the maintenance of the grassland. Rather, fire would be critical only with enough regularity to prevent trees from growing large enough to become invulnerable to grass fires.

Another grazing related influence is the role of dense herds of grazers on controlling woody vegetation and stimulating grasses. Savory (1998) has stressed the importance of herding grazers on maintaining grasslands and has emphasized the extremely different consequences of typical human-controlled grazing regimes (long periods of exposure to low densities of animals) and natural systems (large migratory herds at high density due to threat of predation). He has noted that extremely high densities of grazers (and thus damage to woody plants) may be of critical importance in preventing encroachment of woody vegetation and shifting the balance in favor of grazing adapted grasses. A different impact of grazers is that seed dispersal may be of major importance in the invasion of grasslands by certain woody species. Data of Brown and Archer (1999) suggest that rates and patterns of seed dispersal may be the primary de-

terminants of encroachment by mesquite (*Prosopis glandulosa*) on present-day landscapes in semi arid regions of the American southwest.

Still another confounding factor is the competition for resources between grasses and woody species in an intact prairie ecosystem. Under certain conditions (e.g., of soil, water, grazing, etc.) on an intact prairie, grasses might be able to out compete woody species or at least resist their invasion, with or without the influence of fire. However, the impact of fire and grazing are of critical importance since under natural conditions it is unlikely that either of these factors would be absent for any significant length of time.

CONCLUSION

The soil-mediated fire frequency hypothesis is merely a particular case of a group of mechanisms that, by reducing the frequency and intensity of fire, enable trees to grow where grass would otherwise dominate. The fire induced state of grasslands on the Prairies is therefore apparently destabilized when fire is suppressed for any of a number of reasons. In addition to the hypothesized effect of soil on grass biomass, other variables that can hinder fire and thus allow trees to invade include precipitation, grazing, and topography (Collins & Wallace 1990; McPherson 1995). Trees invade when rainfall prevents fire throughout the year (e.g., in areas of eastern deciduous forest in the eastern U.S). Likewise, reduced grass biomass from grazing on the Prairies reduces fire likelihood, which in turn enables invasion by trees (Smeins et al. 1982; Scholes & Archer 1997; Van Auken 2000). As noted by Van Auken (2000), "the driving force [for brush encroachment] seems to be chronic, high levels of herbivory by domestic animals. This herbivory has reduced the aboveground grass biomass, leading to the reduction of fine fuel and a concomitant reduction or complete elimination of grassland fires. This combination of factors favors the encroachment, establishment, survival and growth of woody plants." Finally, where relief is extreme, as on scarps or cliffs, woodlands are often present. This is due to both the thin rocky soil (and hence low grass biomass) and the topography (e.g., abrupt scarps), which often creates natural firebreaks (Wells 1965, 1970; Axelrod 1985). Thus, any factor that reduces fire likelihood, frequency, or intensity can be expected to allow trees to invade grasslands in areas where there is sufficient moisture for tree growth. The soil-mediated fire frequency hypothesis for the historical distribution of the Prairies and Woodlands of North Central Texas and East Texas is consistent with both historical vegetation patterns and recent changes in the vegetation, and is simply a special case of a generally accepted explanation for tree-grass interactions.

BOOK NOTICES

HOWARD GARRETT. 2002. **Howard Garrett's Texas Trees.** (ISBN 0-89123-076-9, hbk.). Taylor Wilson, 1900 West Loop South, Suite 1900, Houston, TX 77027, U.S.A. (Orders: 713-980-1950, fax 713-980-2429, 800-570-0082, www.taylorwilson.com). $29.95, 253 pp., color throughout, 7" × 10".

Texas is a big state with a wide range of climate, soil and water quality, and knowing when to plant the proper tree is crucial. *Howard Garrett's Texas Trees* is a handy reference for everyone from your basic gardener to degreed botanist. According to Dr. Garrett "This book is about horticultural details, as well as my opinions on weather and how to use the various trees available in Texas."

Everything needed to identify over 100 varieties of Texas trees is here in this one source—along with easy-to-follow directions for selecting, planting, and maintaining your trees. Howard takes a very common sense approach (as with all his books) to planting, propagating and all things trees.

Included in the book is an in-depth Tree Glossary with full details (and great color photos) as well as descriptions of natural habitats, identification information, maintenance, propagation, problems, culture, flowers, fruit, and foliage. Also included is a handy little index of pests, diseases, funguses and organic treatment methods, like the Basic Organic Program, which Garrett developed.

In summary, I would like to recommend adding this book to your library. It's an excellent reference for native and introduced trees to the region, and would be a great reference guide for anyone in the botanical world.—*Asha McElfish, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX 76102-4060, U.S.A.*

MICHAEL A. ARNOLD. 2002. **Landscape Plants for Texas and Environs, Second Edition.** (ISBN 1-58874-153-2, hbk.). Stipes Publishing L.L.C., 202-204 West University Ave. P.O Box 526 Champaign, Ill. 61824-0526 (Orders: 217-356-8391, stipes@soltec, www.stipes.com). $68.00, 1088 pp., line drawings, maps, 8 1/2" × 11".

Dry, but well-researched and to the point is how I would best describe Arnolds newest book, *Landscape Plants for Texas and Environs*. According to the book "The text was developed as a reference for nursery and landscape professionals and as a study aide for students of Texas landscaped plants."

The book probably won't win any design award, as the pages are laid out it in a plain black and white blocked format with large line drawings and species descriptions; no color photographs are found in the book except on the covers.

For each species covered it includes: Other Common Names, Family, Cold Hardiness, Foliage, Flower, Fruit, Stem/Bark, Habit, Cultural Requirements, Pathological Problems, Ornamental Diseases, Limitations & Liabilities, Landscape Utilization, Native habitat, and Related Taxa.

Personally I find this book to be lacking in the attention grabbing area of color, but it is easy to read, well-researched, and you can find what you're looking for quickly. Definitely not a book you put on your coffee table to show off, but one you will probably find yourself wanting when researching the Texas flora for landscape plants.—*Asha McElfish, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX 76102-4060, U.S.A.*

ABSTRACT

One-hundred twenty-two species of seed plants, representing 95 genera and 35 families are documented for the 7,700 ha Mohawk Dune Field and its immediate surroundings, located in Yuma County, Arizona, USA. Three major habitats were studied: dunes, adjacent sand flats, and playa. The dunes (including interdune swales) support 78 species, of which 13 do not occur on the adjacent non-dune habitats. The adjacent non-dune habitats (sand flats and playa) support 109 species, of which 43 were not found on the dunes. The total flora has 81 annual species, or 66% of the flora. The dune flora has 63 annual (ephemeral) species, or 81% of the flora—one of the highest percentages of annuals among any regional flora. Of these dune annuals, 53 species (84%) develop during the cool season. No plant taxon is endemic to the Mohawk region. There are 8 dune, or sand adapted, endemics—*Cryptantha ganderi, Dimorphocarpa pinnatifida, Dicoria canescens, Ditaxis serrata, Pleuraphis rigida, Psorothamnus emoryi, Stephanomeria schottii, Tiquilia plicata*—all of which are found on nearby dune systems. Two of them (*C. ganderi* and *S. schottii*) are of limited distribution, especially in the USA, and have G2 Global Heritage Status Rank. There are four non-native species in the dune flora (*Brassica tournefortii, Mollugo cerviana, Sonchus asper, Schismus arabicus*), but only *Brassica* and *Schismus* seem to pose serious threats to the dune ecosystem at this time. The Mohawk Dune field is within the Lower Colorado Valley phytogeographic region of the Sonoran Desert and located within the Barry M. Goldwater Military Range. This unique dune system, largely unaffected by human activities, is recommended as a site for baseline studies of plant migrations and population dynamics affected by global climatic change.

RESUMEN

Ciento veintidos especies de espermatófitos, que representan 95 géneros y 35 familias se documentan para las 7.700 ha del Mohawk Dune Field y sus alrededores, en el condado de Yuma, Arizona, USA. Se estudiaron tres grandes hábitats: dunas, arenales planos, y playas. Las dunas (incluyendo las depresiones interdunares) tienen 78 especies, de las que 13 no se dan en los hábitats no dunares adyacentes. Los hábitats adyacentes no dunares (arenales planos y playa) tienen 109 especies, de las que 43 no se encontraron en las dunas. La flora total tiene 81 especies anuales, o el 66% de la flora. La flora dunar tiene 63 especies anuales (efímeras), o el 81% de la flora—uno de los porcentajes más altos de anuales en las floras regionales. De estas anuales dunares, 53 (84%) se desarrollan durante la estación fría.

DUNE SYSTEMS AND ENVIRONMENT

Dunes inspire thoughts of barren desert, windblown and inhospitable. Yet dunes can support substantial and unique plant life. Sand dunes occur around the globe

SIDA 20(3): 1155–1187. 2003

as both coastal and inland systems, and are not restricted to deserts but are often prominent features of major deserts. Dunes are relatively rare in the Americas, covering about 0.5% of the arid zones in North America (Bowers 1982, 1984). The major Sonoran Desert dune fields are the Gran Desierto Dunes of northwestern Sonora and the related Algodones Dunes of southeastern California. Hot-desert dune plant communities must cope with an array of challenging growth conditions, including burial, root exposure, wind shear, and low nutrient levels. As a result, dune floras are frequently characterized by high levels of endemism and specialized adaptations (Bowers 1982). Despite these challenges, Shreve (1951:127) pointed out that "Sand...is a particularly favorable soil for the ephemerals of the cool season, because of the deep infiltration of moisture and the rapid warming of the surface early in the season and early in the day."

This publication reports the composition and characteristics of the flora and vegetation of the Mohawk Dunes, reflecting accumulated data from numerous visits to the area by the authors spanning more than five years, as well as herbarium records of other collectors. The first section describes dune systems and the physical environment, management, and global significance of the Mohawk Dunes in particular. The second section is a description of the Mohawk Dune vegetation and flora, and the third catalogues its flora, containing species accounts for each of the 123 species of the dune system and the immediately adjacent desert flats.

PHYSICAL CHARACTERISTICS OF THE MOHAWK DUNES

The Mohawk dune field is located about 65 km east of Yuma, Arizona, on the eastern side of the Mohawk Valley in Yuma County (Broyles et al. 1997). The region is within the Lower Colorado Valley phytogeographic subdivision of the Sonoran Desert (Shreve 1951). The Mohawk Valley is roughly 28 km wide, forming a nearly flat plain with moderately sandy soils. Steep, rocky mountain fronts bound the valley to the east and west, similar plains stretch far to the south, and the north end is bounded by agricultural fields along the now usually dry Gila River. The valley lacks any well-defined central drainage channel, with the mountain fronts draining into ephemeral stream channels, which rapidly shrink to insignificance. The elongated dune system runs parallel to, and west of the Mohawk Mountains, trending northwest to southeast (Fig. 1). Small, scattered outlier dunes occur in the San Cristobal Valley east of a pass in the Mohawk Mountains. The Mohawk dune field is about 32 km long and varies in width up to 3.2 km wide, covering approximately 7,770 ha. Maximum elevation is 207 m near the center of the dunes, rising about 55 m above the surrounding desert. The underlying desert floor rises gently from an elevation of 116 m at the north end of the dunes to 192 m at the south end (Smith & Bender 1973).

The dune contours consist of a fairly regular series of depressions surrounded

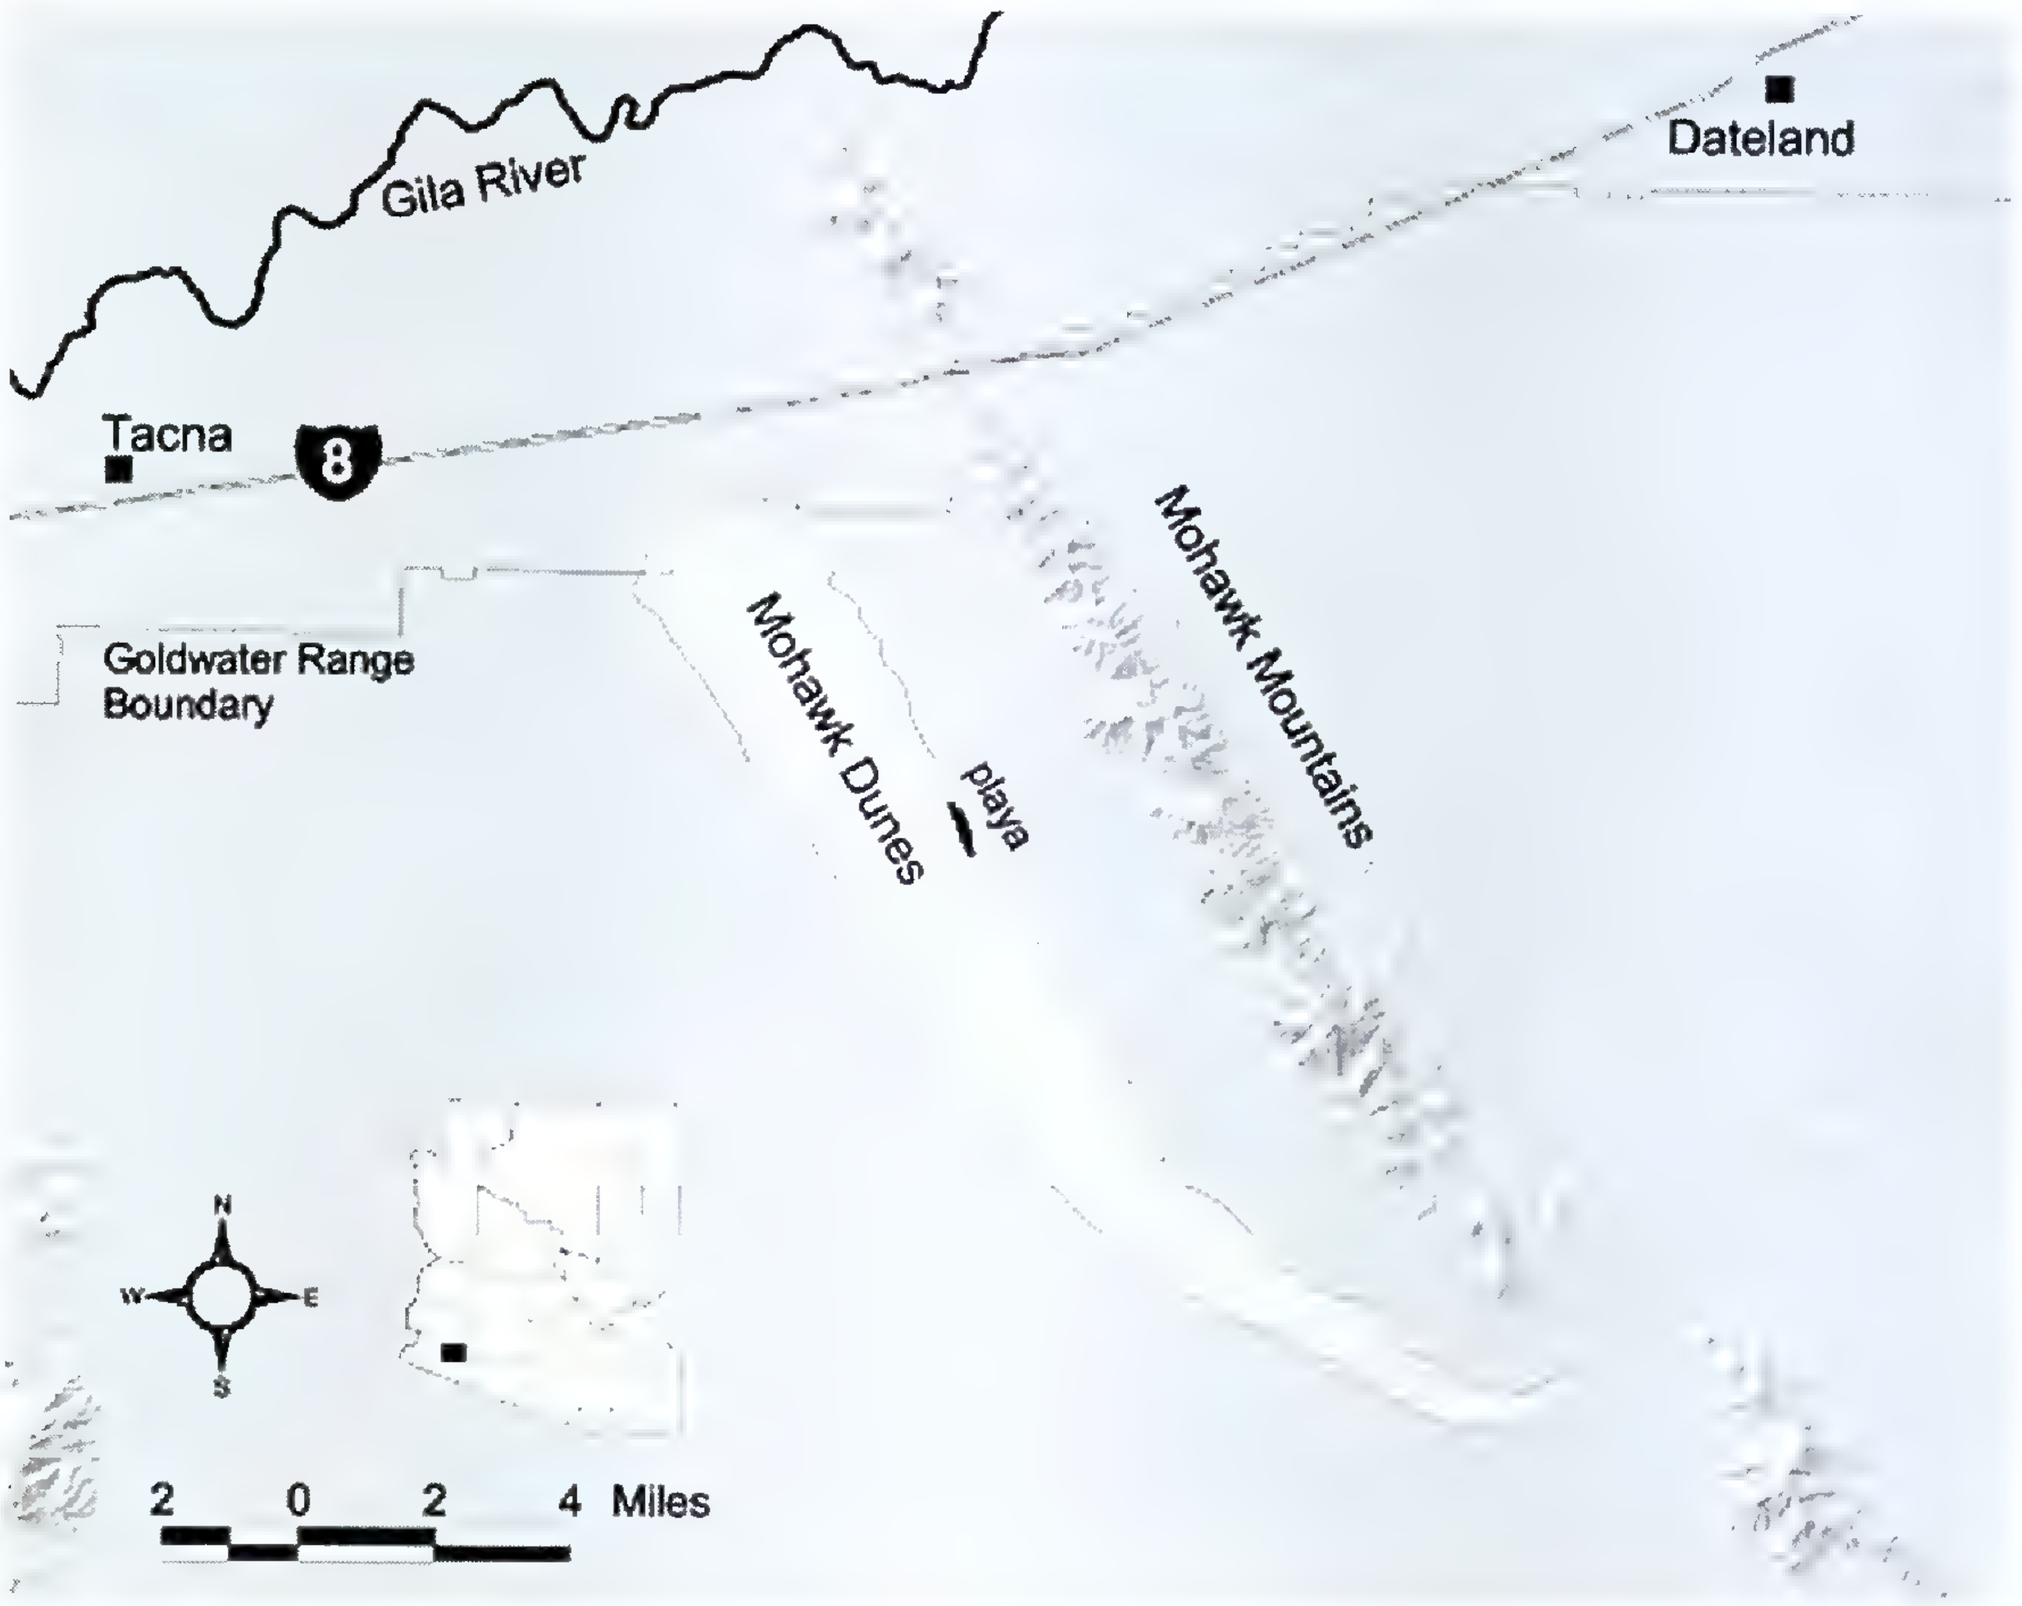

FIG. 1. Location of Mohawk Dunes in southwestern Arizona.

by ridges, resembling a honeycomb in aerial view. Swales—low areas between dunes—and the surrounding crests form microhabitats with significantly different plant and animal communities. The crests are characterized by shifting or slightly stabilized sands and a dominance of sand-adapted species. In contrast, the swales have soil textures and species assemblages that more closely resemble the desert surrounding the dune field (Turner et al. 1997a). The swales are also notable for having a much more stable surface. This is largely maintained by a well-developed microbiotic crust dominated by the cyanobacterium *Microcoleus vaginatus* and the lichen *Collema* sp. (Jane Belnap, pers. comm.).

The Mohawk Dune system appears to have been in place for an extended period. Extensive layers of calcium carbonate are evident on swale slopes, and we have found numerous fossil remnants of tortoises and other vertebrates. The dune sand is composed mainly of quartz and feldspar. According to Bowers (1986:57), "... the Mohawk Dunes have garnered all the sand available for their formation: no more sand is being blown into the dune field." It seems reasonable to suspect that an earlier configuration of the Gila River was the source of sand for these dunes, but that question remains unstudied.

A distinctive playa (the bed of an ephemeral lake), 1,400 m × 250 m, lies along the eastern side of the dunes, about 8 km south from the dune field's north end (Fig. 1). It appears to fill to a depth of <1 m with a frequency of about once per decade, most recently in winter 1992–93. Its more common aspect features sun-baked clay with an extensive network of deep cracks.

Climate

Air temperature regimes for the area are typical of the lower Sonoran Desert, with mean daily maxima of 40-43°C for June through September, and peaks in excess of 49°C during midsummer (Sellers & Hill 1974). Surface temperatures on the dunes reach greater extremes, with June and July maxima averaging above 65°C in 1996. Relative humidity is generally low, dropping below 10% on most days in the summer and many days in winter (Turner, unpubl. data).

Annual rainfall averaged 10.54 cm from 1900-1951 at the nearest weather station, Mohawk, ca. 5 km northeast from the north end of the dune field. About half of the annual total, 4.85 cm, fell during the May-October warm season, primarily during July-September, while 5.72 cm fell November-April (Sellers et al. 1985). Months with no rain are common, and summer storms can deliver a large fraction of the total annual precipitation in a short period (Sellers & Hill 1974).

Although rainfall data from nearby stations may be indicative of regional trends and normal year-to-year variation, they may not provide accurate data on local precipitation. A six-year study in Yuma showed that summer rainfall can vary by more than 2.5 cm for sites only 1.6 km apart (Turnage & Mallery 1941). Rain gauges at the Mohawk Dunes separated by 9.3 km recorded 2.54 and 0.38 cm for the same period of August through October 1994. The same two gauges recorded 0.46 and 3.30 cm respectively for a single storm event in July 1996 (Turner, unpubl. data). Such variation can cause dramatic differences in vegetative composition and abundance between sites.

Mohawk Dunes as a Long-Term Research Site

The Mohawk Dunes and surrounding landscape are part of the Barry M. Goldwater Military Range, jointly managed by 56th Range Management Office at Luke Air Force Base and the Range Management Department at Marine Corps Air Station, Yuma (Felger et al. 1997; Tunnicliff et al. 1986). The western part of the range including the Mohawk Dunes is managed by the Marine Corps and lands to the east are managed by the Air Force. Civilian access requires permission from the military. Military activities have impacted only approximately 5-12% of the entire 690,000 ha Goldwater Range and have had very little apparent affect on the dune biota. To date the military has provided substantial protection from the damaging recreational activities common to other dune systems in the American Southwest, and the Mohawk Dunes remain largely unaffected by human activity. However, future military and civilian effects on the dunes will be determined by management plans now under discussion.

The dunes are a popular destination for the public during spring wildflower displays, and there is occasional illegal off-road driving. Planning should assure undisturbed areas for monitoring and research, while other areas have access but with precautions to insure minimal impact.

Our understanding of global diversity is hindered by the lack of knowledge of changes in species composition over time so that processes of colonization, extinction, and evolution cannot be thoroughly described. This underlines the importance of maintaining areas that remain undisturbed by human development and that have protected status or the potential for protection due to land ownership. The manageable size of the Mohawk Dunes makes them an excellent candidate as a long-term research site. Careful stewardship of the dune field will serve to protect their value to our understanding of ecosystem processes.

METHODS

This report reflects accumulated data from numerous trips to the area with primary collections during 1995-1998. Specimens are at ARIZ, with duplicates for most species variously going to other herbaria, e.g., ASU, RSA, SD, and the Yuma District Office of the Bureau of Land Management. We also examined additional specimens, primarily at ARIZ, ASU, and RSA.

As part of an ecological inventory and monitoring program (Turner et al. 1997 a, b), plant cover sampling was done at two sites in the dune system using a stratified random sampling design to characterize the crest and swale plant communities. This involved randomized placement of quadrats along curvilinear transects which stayed either on crests or in swales, along transects which were previously established for a lizard monitoring program. Dune crests were sampled with a 1-km transect at a site on the east side of the dunes near the playa and two 500-m transects on the west side. Swales were sampled with a single 1-km transect near the playa.

We used quadrats 0.5 × 2 m, to take 200 samples out of a 10-m-wide swath along each 1-km transect, or 100 samples for each 500-m transect, for a representative sample of 1 ha for each sample site. Sampling was conducted during March 1996, following an unusually dry year, and thus measured almost exclusively perennial species.

VEGETATION AND FLORA

The total flora of the Mohawk Dune Region (dune and non-dune habitats) is comprised of 122 vascular plant species in 95 genera and 35 families. The most diverse families are the Asteraceae, Fabaceae, Poaceae, and Brassicaceae (Table 1). The most diverse genera are *Camissonia* with 4 species and two subspecies, *Cryptantha* with 4 species, and *Ambrosia* and *Boerhavia* each with 3 species. The growth-form spectrum is shown in Fig. 2. The different life forms are more

or less evenly distributed between the dunes and sand flats except that all but one (*Prosopis*) of the tree and large-shrub species (microphanerophytes) are absent from the dunes (Table 2). The total flora has 81 annual or ephemeral species, or a remarkable 66% of the flora (see discussion below for dunes). In contrast the ephemeral/annual flora of northwestern Sonora comprises 46% of the total flora, and across much of the Sonoran Desert the ephemerals make up about 50% of the total flora (e.g., Felger 2000; Venable & Pake 1999).

During the warmer months, often April and early May, and again with summer-early fall rains, many of the common ephemerals can be ravaged by caterpillars of the white-lined sphinx moth (*Hyles lineata*) (Fig. 10). Plants favored by these caterpillars include *Allionia incarnata*, *Boerhavia* spp., *Euphorbia abramsiana*, *Kallstroemia californica*, *Lupinus arizonicus*, and *Pectis papposa*.

Vegetative cover by perennial plants

Vegetative cover data were gathered during an unusually dry spring. Eight plant species were found living in 600 quadrats. We found almost no annual plants at that time. Mean ground cover on the dune crests ("dunes") ranged from 7-15%, while that in the swales was about 9% (Table 3). Dominant perennial species on the crests included *Ambrosia dumosa*, *Aristida californica*, *Ephedra trifurca*, *Pleuraphis rigida*, and *Psorothamnus emoryi*. The swales had a similar suite of species, with the addition of *Larrea divaricata* and a strong reduction in *Psorothamnus emoryi*.

Habitats

Bowers (1982) found that plant communities on dunes are mixtures of dune endemics, widely distributed plants of sandy soils, and plants found in adjacent, non-dune habitats. The desert flats, or sand flats, and the small playa are the non-dune habitats adjacent to the Mohawk Dunes.

Dunes.—During years of favorable winter-spring rainfall, such as certain El Niño years, the dunes support spectacular displays of wildflowers. Among the most conspicuous are sand verbena (*Abronia villosa*), desert marigold (*Baileya* spp.), desert cryptantha (*Cryptantha angustifolia*), spectaclepod (*Dimorphocarpa pinnatifida*), Arizona lupine (*Lupinus arizonicus*), evening-primrose (*Oenothera deltoides*), and Spanish needles (*Palafoxia arida*). Notably prominent are plants with dense whitish- or silvery-haired leaves and stems, e.g., *Ambrosia dumosa*, *Dicoria canescens*, and *Psorothamnus emoryi*. Deep roots are likewise a common feature, enabling plants to utilize moisture deep in the sand.

The floristic makeup of the dune communities, particularly among perennial species, is highly predictable, with relatively little change in species com- *Psorothamnus emoryi*, *Tiquilia plicata*; Ephemerals—*Abronia villosa*, *Dicoria canescens*, *Dimorphocarpa pinnatifida*, *Lupinus arizonicus*, *Oenothera* plants higher, shifting (moving or unstable) dunes are: Perennials—*Ambrosia dumosa*,

TOTALS: 122 species.	78	101	17	

species, representing 81% of the dune flora, one of the highest percentages of annuals among any regional flora. Of these dune ephemerals, 53 species, or 84% develop during the cool season (41 winter/spring and 12 non-seasonal species), which supports Shreve's (1951:127) statement that sand is a favorable soil for cool-season ephemerals. Non-seasonal ephemerals are those that can germinate and grow with sufficient soil moisture at any time of year (see Felger 2000). Variation in plant cover and dune vegetation is shown in Figs. 3–5.

TABLE 3. Average percent ground cover at three localities in the Mohawk Dunes, March 1996.

Species	E-side dune	E-side swale	W-side dune
Ambrosia dumosa	1.56	4.14	9.07
Aristida californica	0.00	0.89	1.28
Ephedra trifurca	0.97	1.12	1.30

Lupinus arizonicus	0.01	0.01	0.02
Total live ground cover %	6.77	8.95	15.25

Playa.—The main expanse of the playa consists of silty-clay soil riddled with deep fissures. Seventeen species were found on the playa and its margins. Three herbaceous root-perennials are abundant across the expanse of the playa: *Heliotropium curassavicum*, *Hoffmannseggia glauca*, and *Malvella sagittifolia*. Following the occasional times when the playa fills with water, *Sphaeralcea ambigua* and other herbaceous plants may become locally abundant. *Physalis lobata*, *Oligomeris linifolia*, and *Prosopis glandulosa* are locally common around the margin of the playa. The remaining species are uncommon in this habitat or on sandy soils at the playa margin. Four woody plants are known from one or few individuals that probably germinated during the exceptionally wet year of 1992–93: seep willow (*Baccharis salicifolia*), desert broom (*B. sarothroides*), cottonwood (*Populus fremontii*), and tamarisk (*Tamarix ramosissima*). The cottonwood and seep willow perished from drought by the end of 1994 and the tamarisk by June 1996.

Sand flats. Areas surrounding the dune field vary from rolling hills and low sand hummocks to occasionally extensive flats of sandy to silty-sand and clay-sand soils. These habitats, collectively called "sand flats," support 101 species within ca. 1 km of the dune margins (Table 2). Nearly 30% of these species were not found on the dunes.

Desert shrubs, namely creosotebush and the two bursages (*Ambrosia deltoidea* and *A. dumosa*) are the most common, widespread elements in the landscape. Several cacti and crucifixion thorn (*Castela emoryi*) are widely but thinly scattered across the landscape, and patchy areas of ocotillo (*Fouquieria splendens*), ratany (*Krameria erecta*), and several other perennials are locally prominent.

The sand flat habitats and vegetation grade into those of the dunes, and less noticeably into the surrounding valley plains and vegetation. But common shrubs such as creosotebush (*Larrea divaricata*) tend to be noticeably less dense on these sandy areas than the surrounding plains.

FIG. 3. Mohawk Dunes, during a "wet spring," 28 February 1998. *Oenothera deltoides* (white flowers) *Abronia villosa* (lavender-pink flowers), and *Pleuraphis rigida* (background). Looking eastward, Mohawk Mountains in background. Photo by Thomas R. Jones.

Comparison to Other Dune Systems

In terms of plant diversity and species composition, the Mohawk Dunes, as expected, show the greatest affinity to other inland dune systems within the Sonoran Desert. Of these, the greatest similarity exists with dunes of the Gran Desierto, Sonora, the largest inland dune system in North America (5,000 km^2), centered approximately 70 km to the southwest of the Mohawk system (Felger 1980, 2000). The Pinta Sands of Cabeza Prieta National Wildlife Refuge, 38 km to the south are the closest dune system, but these dunes are only a northern extension of the Gran Desierto, being some 5 km from the northernmost dunes of that system. The Algodones dunes (709 km^2) of southeastern California, 90 km to the west, share many plants with the Mohawk system (*see* WESTEC Services 1977). Although no plant is endemic to the Mohawk Dune system alone, *Cryptantha ganderi*, *Dimorphocarpa pinnatifida*, and *Stephanomeria schottii* are endemic to dunes and adjacent sand flats of the Lower Colorado region of the Sonoran Desert.

The Mohawk system has among the highest species richness for its size

among southwestern dunes. The enormous Gran Desierto dune system has a flora of only 85 species (Felger 2000), amazingly few species for such an immense area. The relatively low species richness probably can be attributed to the low habitat diversity, extreme aridity, and harsh conditions brought about by moving sand. The Mohawk Dunes, with less than 2% of the area, supports a dune flora of 78 species (Table 2). The Algodones Dunes are reported to support a flora of 97 species (Bowers 1984, interpreting WESTEC Services 1977; this number, however, cannot be considered wholly accurate based on the available data). The Kelso Dunes in the eastern Mohave Desert support 75 species (Thorne et al. 1981), with some overlap with Mohawk Dune species. It is interesting to note the similarity in species richness among these diverse dune systems.

Species composition of the dominant dune vegetation in the Mohawk Dunes is similar to that of other Sonoran Desert dune systems (Felger 2000; Warren & Laurenzi 1987). Five species typically comprise at least 90% of the perennial vegetative cover on these systems, with *Ambrosia dumosa* and *Pleuraphis rigida* the most abundant, and *Psorothamnus emoryi*, *Ephedra trifurca*, and *Tiquilia plicata* as common associates.

Absent from the Mohawk Dunes are several dune-endemic species which are relatively common in the Gran Desierto and/or Yuma Dunes and Algodones Dunes, including *Asclepias erosa*, *Croton wigginsii*, *Drymaria viscosa*, *Eriogonum deserticola*, *Euphorbia platysperma*, *Helianthus niveus*, *Heterotheca thiniicola*, *Pholisma sonorae*, *Larrea divaricata* var. *arenaria*, *Palafoxia arida* var. *gigantea*, and *Triteleiopsis palmeri* (e.g., Felger 1980, 2000; Felger et al. 1997). This may be due to the relative isolation of the Mohawk Dunes. *Eriastrum eremicum*, found on the Mohawk Dunes is not present at the other dune systems; it is more characteristic of Arizona Upland locales and has its southwestern limits near the Mohawk Dunes.

Non-native Species

Five non-natives species, all native to the Old World, are recorded in the flora: *Brassica tournefortii*, *Mollugo cerviana*, *Schismus arabicus*, *Sonchus asper*, and *Tamarix ramosissima*. *Tamarix* is no longer present, and the remaining four occur on the dunes and all but *Mollugo* are also found on the sand flats. The *Brassica*, *Mollugo*, and *Schismus* are common and well established, while *Sonchus asper* is widely scattered but not common. Additional invasive weedy species undoubtedly will arrive on the scene. A number of non-native, weedy plants are conspicuously absent from the Mohawk flora but are common in nearby, mostly disturbed areas, e.g., buffelgrass (*Pennisetum ciliare* (L.) Link) and tumbleweed (*Salsola tragus* L.).

A flora with only 4% non-native species is remarkable, since the average for the Sonoran Desert is about 11.6% (Felger 2000; Wilson et al. 2002). It is not, however, unusual for regional dune systems. The Mohawk Dunes and the enor-

mous Gran Desierto dune system contain only the same four non-native species and the abundance patterns are likewise similar (see Felger 2000:21). The unusually low number of non-natives may be due to the uniqueness, isolation, and relatively undisturbed condition of the habitat.

Although competition between plants on dunes is reported to be negligible (Bowers 1982), *Brassica tournefortii* and *Schismus arabicus* certainly seem invasive and detrimental to native species (Felger 2000; Wilson et al. 2002). Their very rapid early growth seems to negatively affect native plants. On the Mohawk dunes as well as elsewhere in the Sonoran Desert (e.g., Felger 2000), *Brassica* rosette-leaves and *Schismus* plants spread over seedling and juvenile plants of the apparently slower-growing native ephemerals, possibly smothering or shading them out, or preventing their germination (Fig. 6).

ANNOTATED SPECIES ACCOUNTS

The flora is listed alphabetically by family, genus, and species. Accepted scientific names, including the variety (var.) or subspecies (subsp.), are in **bold**. Selected synonyms of scientific names are in *italics* within brackets [-]. Common names follow the scientific names, and when known are given in English and Spanish. Brief characterizations are provided for each species, including the usual flowering time and in most cases the general or most conspicuous color of the flower (flower color is often omitted for species with small, inconspicuous flowers). Growth and flowering, of course, is almost entirely linked to rainfall and soil moisture. During extended drought, such as 2001 and 2002, many plants fail to grow or flower. More detailed descriptions and distributional information can be found in many sources, e.g., Felger (1980, 2000), Hickman (1993), Kearney and Peebles (1960), Wiggins (1964), and the various contributions to the Vascular Plants of Arizona (Vascular Plants of Arizona Editorial Committee 2001).

The distributional information is based on field observations and for the most part verified with herbarium specimens primarily at the herbaria of the University of Arizona (ARIZ) and Arizona State University (ASU). Specimens cited are at ARIZ, unless otherwise indicated, and in many cases duplicates, especially those of Felger, are mostly at ASU, RSA, and SD. The five non-native species are indicated with an asterisk (*). The area had abundant spring rains during 1995 and 1998, and abundant summer rains during 1996 and 1997. In our opinion we likely encountered plants of nearly all of the ephemeral species present in the seed bank as well as all of the perennials.

AMARANTHACEAE - Amaranth Family

Amaranthus fimbriatus (Torr.) Benth. ex S. Watson. Fringed pigweed; *bledo, quelitillo*. Hot-weather annuals; flowers greenish and white. Sand flats and dunes. *Felger 97-63 et al.; Felger 96-138 & Turner.*

Amaranthus palmeri S. Watson. Carelessweed, pigweed; *bledo, quelite de las aguas*. Hot-weather annuals. Sand flats, especially near

FIG. 6. Northeast side of Mohawk Dunes looking northwest. *Schismus* in left foreground, *Abronia* (lavender-pink flowers), *Pleuraphis* in right foreground, dune swale in mid-distance, and dune slope in background with *Larrea* and *Abronia*. April 1998. Photo by Charles Hedgcock.

the south end of the dune field. *Felger 97-79 et al.*

Tidestromia lanuginosa (Nutt.) Standl. subsp. **eliassoniana** Sanchez-del Pino & Flores Olvera. Honeysweet; *hierba ceniza, hierba lanuda*. Hot-weather annuals; flowers yellow. Widespread and common, sand flats and dunes. *Felger 97-71 et al.; Felger 96-149 & Turner.*

ASCLEPIADACEAE - Milkweed Family

Asclepias subulata Decne. Desert milkweed, reedstem milkweed; *jumete, mata candelilla*. Perennials with multiple, semi-succulent stems; flowering during warmer months; flowers waxy, cream- and yellow-white. Occasional in washes in sand flats near north side of dune field. *Turner s.n., 12 Nov 2001.*

Funastrum cynanchoides (Decne.) Schlt. var. **hartwegii** (Vail) Krings [*Sarcostemma cynanchoides* Decne. subsp. *hartwegii* (Vail) R.W. Holm; *Funastrum heterophyllum* (Engelm.) Standley]. Climbing milkweed; *güirote*. Perennial vines; flowering at various seasons; flowers maroon and white. Occasional in washes in sand flats near the northern part of the dunes. *Felger & Turner*, 24 Sep 1996, observation.

ASTERACEAE - Daisy or Composite Family

Ambrosia confertiflora DC. Slimleaf ragweed; *estafiate*. Herbaceous perennials; flowering late spring and in fall. Occasional in depressions in sand flats near the dunes. *Felger 97 77 et al.*

Ambrosia deltoidea (Torr.) W.W. Payne. Triangle-leaf bursage; *chamizo forrajero*. Small shrubs. Common on dunes, sand flats, and playa margins. Summer dormant. *Felger 96 169 & Turner; Reina-G. 96-213 & Van Devender.*

Ambrosia dumosa (A. Gray) W.W. Payne. White bursage; *chamizo*. Small shrubs; flowering September-April. Summer-dormant, new leaves and flowers may appear as early as September. Very common on sand flats and dunes including higher dunes. *Felger 97-66 et al.; Felger 96-127 & Turner; Reina-G. 96-215 & Van Devender.*

Baccharis salicifolia (Ruiz & Pav.) Pers. [*B. glutinosa* Pers.]. Seep willow; *batamote*. Leafy shrubs. About ten plants, mostly 2-2.5 m tall, along the southern edge of the playa apparently grew during the exceptionally wet year of 1992-1993, and perished by the end of 1994. *Felger 96-154 & Turner.*

Baccharis sarothroides A. Gray. Desertbroom; *escoba amargo, romerillo*. Broomlike shrub. One individual, ca. 2 m tall, at northeast margin of playa. *Felger 96-150 & Turner.*

Baileya pauciradiata Harv. & A. Gray ex A. Gray. Few-flowered desert marigold. Spring annuals; flowers yellow. Dunes and sand flats. *Reichenbacher 601; Salywon et al. 988* (ASU); *Turner 95-26.*

Baileya pleniradiata Harv. & A. Gray ex A. Gray. Woolly desert marigold; *tecomblate*. Annuals, mostly in spring, sometimes with summer rains; flowers yellow. Dunes and sand flats. *Felger 98-56 & Evans; Salywon et al. 987* (ASU); *Turner 95-25, 95-30.*

Chaenactis stevioides Hook. & Arn. Desert pincushion. Cool-season annuals; flowers white or cream, pink in bud. Dunes, especially lower dunes, and sometimes on sand flats. *Felger 98-58 & Evans; Goldberg 77-87; Turner 95-5.*

Dicoria canescens A. Gray subsp. **canescens**. Bugseed. Annuals; germinating at least with spring rains, their numbers variously reduced by late-spring and early summer drought, recorded fully leafed-out in August, and variously flowering from late October through December; plants often robust to 1 m tall and becoming tumbleweeds after seeds ripen. Seedlings and juvenile plants quickly produce a deep taproot and have narrow, elongated leaves, the older plants produce broad and shorter leaves. Restricted to dunes, especially moving sands of higher dunes. On 24 November 1994, Turner observed plants in full bloom, abuzz with honeybees but no native bees; the honeybees probably were gathering pollen since the plants are presumably wind-pollinated. On 23 June 1995, Turner found clipped stems and leaves scattered around stripped stems—evidence of herbivory by kangaroo rats (*Dipodomys* sp.). *Felger 98-59 & Evans; Reichenbacher s.n., 7 Mar 1980; Turner 94-2.*

Eriophyllum lanosum (A. Gray) A. Gray. Woolly daisy. Small, cool-season annuals; disk flow-

ers yellow, rays white. Sand flats. *Felger 98-91 & Evans.*

Filago arizonica A. Gray. [*Logfia arizonica* (A. Gray) Holub]. Arizona fluffweed. Small, cool-season annuals. Low areas in sand flats. *Felger 98-93 & Evans.*

Geraea canescens Torr. & A. Gray. Desert sunflower, desert gold. Coarse spring annuals; flower heads sunflower-like, bright yellow. Dunes and sand flats. *Goldberg 77-89; Turner 95 27.*

Isocoma acradenia (Greene) Greene var. **acradenia** [*Haplopappus acradenius* (Greene) S.F. Blake]. Alkali goldenbush. Small shrubs; flowering various seasons, at least in spring and fall; flowers yellow. Occasional and localized at the playa margin and sand flats at roadsides. *Felger 96-143 & Turner, 96 155; Reina-G. 96-214 & Van Devender.*

Malacothrix glabrata (A. Gray ex D.C. Eaton) A. Gray [*M. californica* DC. var. *glabrata* A. Gray ex D.C. Eaton] Smooth desert-dandelion. Spring annuals; flower heads white with a pale yellow center. Dune slopes and higher dunes, scattered to sometimes seasonally common. *Felger 98-60 & Evans; Reichenbacher 603; Turner 95-6.*

Monoptilon bellioides (A. Gray) H.M. Hall. Desert star. Small, spring annuals; rays white, turning pale lavender with age, the disk yellow. Sand flats and sometimes on lower dunes; occasional at playa margin. *Felger 98-61 & Evans, 98-96; Turner 95-21.*

Palafoxia arida B.L. Turner & M.I. Morris var. **arida**. Spanish needles. Non-seasonal annuals; flowers white to pink with purple anthers. Sand flats and dunes at all elevations. Some of the larger, robust plants on the dunes approach var. *gigantea* (M.E. Jones) B.L. Turner & M.I. Morris in having larger flower heads and achenes. *Felger 98-4 et al.; Felger 96-139 & Turner; Turner 95-4.*

Pectis papposa Harv. & A. Gray var. **papposa**. Desert chinchweed; *manzanilla del coyote.* Hot-weather annuals; herbage pungently aromatic; flowers bright yellow. Sand flats and dunes. Highly variable in size, drought stressed plants can mature with a single flower head. *Felger 97-56 et al., 97-72; Felger 96-134 & Turner.*

Rafinesquia neomexicana A. Gray. Desert chicory. Spring annuals; flowers white. Dunes, especially dune slopes and swales, also lower dunes and sand flats; mostly growing through small shrubs such as *Ambrosia dumosa. Felger 98-85 & Evans; Felger 98-12 et al.*

***Sonchus asper** (L.) Hill subsp. **asper**. Spiny sowthistle; *chinita.* Winter-spring annuals; flowers pale yellow. Occasional and widely scattered in natural areas such as small arroyos and depression on sand flats, dune swales, lower dunes, and rarely on higher dunes. *Felger 98-62 & Evans, 98-95.*

Stephanomeria schottii (A. Gray) A. Gray. Schott's wire-lettuce. **Fig. 7.** Late spring annuals; flowers white tinged with violet. Seasonally abundant and widespread on dunes at all elevations and also low stabilized dunes of the nearby San Cristobal Valley. *Burgess 5067; Felger 98-16 et al.; Felger 98-63 & Evans; Reichenbacher 596; Turner 95-14.* San Cristobal Valley dunes, *Anderson 98-40, 98-54* (ASU).

Endemic to dunes and sand flats in the Gran Desierto in northwestern Sonora and southwestern Arizona in Yuma County (Felger 2000, Lehto 1979). This species has a Global Heritage Status Rank of G2 (imperiled globally).

Stylocline micropoides A. Gray. Desert neststraw. Small, spring annuals. Locally and seasonally common in swales and depressions among dunes, and sometimes on surrounding sand flats. *Felger 98-83 & Evans.*

BORAGINACEAE Borage Family

Amsinckia tessellata A. Gray. Checker fiddleneck. Cool-season annuals; flowers yellow. Common on dunes and sand flats. *Turner 95-13.*

Cryptantha angustifolia (Torr.) Greene. Narrowleaf cryptantha, desert cryptantha. Cool-season annuals; corollas white with a yellow throat. Widespread across the dunes and sand flats; one of the most common and ubiquitous spring annuals in the region. *Turner 95-12.*

Cryptantha ganderi I.M. Johnst. Cool-season annual, sometimes locally common; flowers minute, white; fruits with 2 smooth nutlets.

FIG. 7. *Stephanomeria schottii*, dunes, early morning, May 8, 1999. Photo by Charles Hedgcock.

Lower dunes and steep dune slopes; often beneath shrubs such as *Ephedra*. *Felger 98-64 & Evans*.

Dunes and sand flats of the Gran Desierto in northwestern Sonora, and extending into adjacent southwestern Arizona on the Pinta Sands in Cabeza Prieta National Wildlife Refuge, and disjunct on the Mohawk Dunes, and similar habitats in southeastern California and Baja California. First confirmed for Arizona in 1993 (Felger 2000; Felger et al. 1993). This species has a Global Heritage Status Rank of G2 (imperiled globally).

Cryptantha maritima (Greene) Greene [includes var. *maritima* and var. *pilosa* I.M. Johnst.]. White-haired cryptantha. Cool-season annuals; corollas white. Widely scattered on sand flats. *Felger 98-99 & Evans*.

Cryptantha micrantha (Torr.) I.M. Johnst. subsp. **micrantha**. Dwarf cryptantha. Cool-season annuals; flowers minute, white. Widespread on dunes at all elevations. *Felger 96-164 & Turner*.

Heliotropium convolvulaceum (Nutt.) A. Gray var. **californicum** (Greene) I.M. Johnst. Morning-glory heliotrope. Non-seasonal annuals, mostly germinating and growing during warm weather with sufficient soil moisture; flowers white and showy. Seasonally scattered on dunes. *Van Devender 92-644*.

Heliotropium curassavicum L. [The plants are var. *oculatum* (A. Heller) I.M. Johnst. ex Tidestr., but the variety is probably not worthy of recognition, see Felger 2000]. Alkali heliotrope; *hierba del sapo*. Semi-succulent perennial herbs or facultative annuals; herbage frost-sensitive; corollas white, the center yellow and turning purplish with age. Widespread across the playa, sometimes locally abundant. *Felger 96-152 & Turner; Reina-G. 96-211 & Van Devender; Turner 94-1*.

Pectocarya heterocarpa (I.M. Johnst.) I.M. Johnst. Mixednut comb-bur. Cool-season annuals; corollas white with a yellow center. Widespread and common, dunes and sand flats. *Felger 98-65 & Evans*.

Pectocarya platycarpa (Munz & I.M. Johnst.) Munz & I.M. Johnst. Broadwing comb-bur. Cool-season annuals; flowers white. Dunes and sand flats. *Felger 98-90A & Evans*.

Tiquilia plicata (Torr.) A.T. Richardson. Fanleaf crinklemat. Perennial herbs from deep, thick and black roots; flowering spring and summer; corollas lavender. Mostly on moving dunes, occasional on low sand hills on sand flats. *Felger 97-70 et al.; Felger 96-136 & Turner; Reichenbacher 599*.

BRASSICACEAE (CRUCIFERAE) - Mustard Family

***Brassica tournefortii** Gouan. Sahara mustard, wild turnip; *mostaza*. Cool-season annuals; plants highly variable in size; flowers pale yellow and apparently selfing (Felger 2000). Widespread and especially abundant on dunes during years of high winter spring rains; sand flats and dunes including highest dunes. Larger plants with basal rosette leaves each to 72 cm long, these leaves spreading close to ground and often covering other spring annuals. The leaves are bitter tasting except those of very small, young plants. *Felger 98 2 et al.; Turner 95-10*.

Caulanthus lasiophyllus (Hook. & Arn.) Payson. Cool-season annuals; flowers minute, white to pinkish. Mostly in swales and on north-facing dune slopes, locally common; also sand flats in washes and swales, mostly at the base of shrubs. *Felger 98-67 & Evans*.

Dimorphocarpa pinnatifida Rollins [*Dithyrea wislizenii* Engelm., in part]. Dune spectaclepod. **Fig. 8.** Cool-season annuals, sometimes more than 1 m across; flowers white and fragrant. Dunes, especially the higher dune crests. Endemic to dunes and sand flats in Yuma County and the Gran Desierto in northwestern Sonora. *Felger 98-6 et al.; Salywon et al. 985; Turner 95-7*. San Cristobal Valley dunes, *Anderson 98-37* (ASU).

Dithyrea californica Harv. Spectaclepod. Cool-season annuals; flowers cream-colored, highly fragrant. Widespread across the dunes, especially lower dunes and slopes. *Felger 98-5 et al.; Salywon et al. 984* (ASU).

Lepidium lasiocarpum Nutt. ex Torr. & A. Gray. Sand peppergrass. Cool-season annuals; herbage peppery-tasting; flowers minute, white. Widespread, mostly on lower dunes and swales, and expected on sand flats. *Felger 98 3 et al.*

FIG. 8. *Dimorphotheca pinnatifida*, dunes, April 1998. Photo by Charles Hedgcock.

Physaria tenella (A.Nels.) O'Kane & Al-Shehbaz [*Lesquerella tenella* A. Nels.]. Desert bladderpod. Cool-season annuals; flowers bright yellow. Sand flats, often growing through bursage (*Ambrosia* spp.). *Felger 98-17 et al.; Felger 98-98 & Evans.*

Streptanthella longirostris (S. Watson) Rydb. Longbeak twistflower. Cool-season annuals; herbage often glaucous and sometimes semisucculent; flowers minute, pale yellowish-white. Widely scattered across dunes, especially swales and north facing slopes, and less common on higher dunes; also sand flats, especially at the base of shrubs. *Felger 98-66 & Evans; Felger 98-7 et al.; Salywon et al. 983* (ASU).

CACTACEAE - Cactus Family

Carnegiea gigantea (Engelm.) Britton & Rose. Saguaro. Columnar cactus; one individual ca. 6 m tall with two large branches. Early summer. Sand flat on east side of dunes.

Cylindropuntia echinocarpa (Engelm. & J.M. Bigelow) F.M. Knuth [*Opuntia echinocarpa* Engelm. & J.M. Bigelow; *O. wigginsii* L.D. Benson]. Silver cholla. Small chollas to 1+ m tall; April; flowers silvery white with green filaments. Mostly lower dunes and swales, especially with harder soils, and sand flats, widely scattered, mostly in small colonies. *Felger & Turner*, 24 Sep 1996, observation.

Echinocactus polycephalus Engelm. & J.M. Bigelow var. **polycephalus**. Many-headed barrel cactus. Multiple-headed, mound-forming barrel cactus; July; flowers yellow. One mature plant (14 living stems) on creosotebush flat near west side of dunes. *Turner*, 27 Jul 1995, photo.

Ferocactus wislizeni (Engelm.) Britton & Rose. Barrel cactus; *biznaga*. Unbranched barrel cactus to ca. 1.5 m tall; flowers orange to red-orange, at least August and September; fruits yellow and fleshy, ripe in late summer and early fall. Occasional and widely scattered on sand flats, especially west side of dunes, and rare on dunes. *Felger 97-52 et al.; Felger 96-165 & Turner, 96-171.*

Grusonia kunzei (Rose) Pinkava [*Opuntia kunzei* Rose. *O. stanleyi* Engelm. ex B.D. Jackson var. *kunzei* (Rose) L.D. Benson]. Desert club cholla. Large club cholla; flowers yellow, summer. One colony, mostly senescent, on low sand hummock on sand flat near southeast margin of dune field. *Felger & Turner*, 25 Sep 1996, observation.

CARYOPHYLLACEAE Pink Family

Achyronychia cooperi Torr. & A. Gray. Sandmat, frostmat. Cool-season annuals; flowers papery white like the stipules. Dunes, especially lower dunes and also on highest dunes and sand flats. *Felger 98-68 & Evans; Salywon et al. 991* (ASU).

CONVOLVULACEAE – Morning-Glory Family

Cuscuta umbellata Kunth. Desert dodder. Warm-season annuals, stems twining; flowers white; parasitic on *Boerhavia* spp. Occasional; dunes and sand flats. *Felger 97-59 et al.*

EPHEDRACEAE - Ephedra Family

Ephedra trifurca Torr. ex S. Watson. Longleaf jointfir, Mormon tea; *canutillo, tepopote*. Robust, spreading shrubs to ca. 1.5 m tall, the trunks and major limbs thick and heavy. Twigs with 3 elongated scale leaves at each node. Dunes and sand flats. Pollen cones mature in March; seeds later in spring. *Felger 98-52 & Evans; Reina-G. 96-208 & Van Devender; Salywon et al. 986* (ASU).

EUPHORBIACEAE - Spurge Family

Ditaxis serrata (Torr.) A. Heller var. **serrata** [*Argythamnia serrata* (Torr.) Müll. Arg.]. Non-seasonal annuals; flowers inconspicuous, green and white. Dunes and sand flats. *Felger 97-51 et al., 98-21b; Felger 96-135 & Turner.*

Euphorbia abramsiana L.C. Wheeler [*Chamaesyce abramsiana* (L.C. Wheeler) Koutnik]. *Golondrina*. Hot-weather annuals; petal like appendages absent or minute. Sand flats and dunes. *Felger et al. 97-57, 97-78 et al.; Felger 96-128 & Turner.*

Euphorbia polycarpa Benth. [*Chamaesyce polycarpa* (Benth.) Millsp.; *E. polycarpa* var. *hirtella* Boiss.]. Desert spurge; *golondrina*. Non-seasonal annuals, but most common during spring; petal-like appendages white, sometimes reduced or absent. Sand flats and

dunes. *Felger 97 53 et al., 97-69; Felger 96 130 & Turner, 96-144.*

FABACEAE (**LEGUMINOSAE**) - Legume Family

Astragalus insularis Kellogg var. **harwoodii** Munz & McBurney ex Munz. Sand locoweed. Cool-season annuals; flowers rose-lavender and white. Dunes, especially lower dunes, and sand flats. *Felger 98-70 & Evans; Turner 95-24.*

Astragalus nuttallianus DC. var. **imperfectus** (Rydb.) Barneby. Smallflowered milkvetch. Cool-season annuals; flowers blue and white. Widely scattered; dunes, mostly swales and lower dunes, and sand flats. *Felger 98-74 & Evans; Felger 98-1 et al.*

Dalea mollis Benth. Silky dalea. Non-seasonal annuals. Dunes, especially lower dunes and dune slopes, and sand flats. *Felger 98-80 & Evans; Reichenbacher 437; Turner 95-27.*

Hoffmannseggia glauca (Ortega) Eifert [*Caesalpinia glauca* (Ortega) Kuntze]. Hog potato; *camote de ratón*. **Fig. 9.** Perennial herbs from deep-seated tuberous roots; flowering non-seasonally with warm weather and sufficient soil moisture; flowers yellow. Common across the playa. *Felger 98-50 & Evans; Reina-G. 96-212 & Van Devender; Turner 95-23.*

Lupinus arizonicus (S. Watson) S. Watson [*L. arizonicus* subsp. *sonorensis* J.A. Christian & D.B. Dunn] Arizona lupine; *lupino*. Cool-season annuals, flowers lavender-pink. Widespread and common, lower to higher dunes, slopes, and dune swales, and sand flats. Plants often ravaged by caterpillars of the painted lady butterfly (*Vanessa cardui*) and the white-lined sphinx moth (*Hyles lineata*; **Fig. 10**). *Felger 98-79 & Evans; Salywon et al. 993* (ASU); *Turner 95-3.*

Marina parryi (Torr.& A.Gray ex A.Gray) Barneby [*Dalea parryi* Torr. & A. Gray ex A. Gray]. Non-seasonal annuals (sometimes short-lived herbaceous perennials elsewhere); flowers dark blue. Dunes and expected on sand flats. *Reichenbacher*, 7 Mar 1980, observation.

Olneya tesota A.Gray. Ironwood; *palo fiero*. Trees ca. 6+ m tall; late April and May; flowers lavender-pink. Washes in sand flats near the northeast and southeast parts of dune field. *Felger & Turner*, 25 Sep 1996, observation.

Parkinsonia florida (Benth. ex A. Gray) S. Watson [*Cercidium floridum* Benth. ex A. Gray]. Blue palo verde; *palo verde*. Trees, ca. 5+ m tall; April, flowers bright yellow. Large wash in sand flats near north end of dune field. *Turner s.n., 12 Nov 2001.*

Parkinsonia microphylla Torr. [*Cercidium microphyllum* (Torr.) Rose & I.M. Johnst.]. Littleleaf palo verde; *palo verde*. Small trees; April and May; flowers pale yellow with a white banner. Scattered along washes in sand flats ca. 1-2 km from northeast and southwest margins of the dune field. *Felger & Turner*, 24 Sep 1996, observation.

Prosopis glandulosa Torr. var. **torreyana** (L.D. Benson) M.C. Johnst. Western honey-mesquite; *mezquite*. Large shrubs to small trees; flowering April and often sporadically through the summer and fall; flowers yellow. Playa margins and washes in sand flats in the surrounding desert, and rarely on dunes including dune swales and crests. Mesquites in the region are intermediate with *P. velutina* Wooton; most leaves have one pair of pinnae, as in *P. glandulosa*, although occasional leaves have two pairs as in *P. velutina*, and the herbage is often moderately pubescent as in *P. velutina* (see Felger 2000). *Felger 96-165 & Turner; Reina-G. 96-207 & Van Devender.*

Psorothamnus emoryi (A. Gray) Rydb. var. **emoryi** [*Dalea emoryi* A. Gray]. Emory indigobush. Shrubs to ca. 1 m tall; flowering after rains, spring and summer; flowers purple and white. Very common on dunes at all elevations and to margins of sand flats. *Felger 96 141 & Turner, 96-163; Felger 97-65 et al.; Reina-G. 96-209 & Van Devender.*

FOUQUIERIACEAE - Ocotillo Family

Fouquieria splendens Engelm. subsp. **splendens**. Ocotillo. Shrubs; spring; flowers red-orange. Common on sand flats at northeast margin of dune field. *Felger & Turner*, 24 Sep 1996, observation.

GERANIACEAE - Geranium Family

Erodium texanum A. Gray. False filaree, desert stork-bill. Cool-season annuals; flowers pink-purple. Sand flats. *Felger 98-18 et al.*

Fig. 9. *Hoffmannseggia glauca*, on the playa, June 1994. Photo by Charles Hedgcock.

HYDROPHYLLACEAE - Waterleaf Family

Nama hispidum A. Gray. Bristly nama. **Fig. 11.** Cool-season annuals; flowers lavender. Dunes and swales, playa margins, and sand flats. *Felger 98-71 & Evans; Turner 95-16.*

Phacelia ambigua M.E. Jones [*P. crenulata* Torr. ex S. Watson; *P. crenulata* var. *ambigua* (M.E. Jones) J.F. Macbr.]. Desert heliotrope. Cool-season annuals; flowers lavender-purple. Sand flats. *Felger 98-89 & Evans; Turner 95-9.*

KRAMERIACEAE Ratany Family

Krameria erecta Willd. ex Schult. [*K. parvifolia* Benth.]. Range ratany. Dwarf shrubs; flowering at least spring and late summer; flowers bright magenta-purple. Widespread on sand flats. *Felger 96-148 & Turner, 96-172.*

Krameria grayi Rose & Painter. White ratany; *cósahui*. Shrubs; flowering various seasons; flowers magenta-purple. Sand flats; apparently rare or at least uncommon in the Mohawk Dune region although common in nearby areas. *Felger 96-147 & Turner.*

LILIACEAE (sensu lato) - Lily Family

Hesperocallis undulata A. Gray. Ajo lily, desert lily; *ajo silvestre*. **Fig. 12.** Perennials from a large, single bulb; flowering stalks sometimes reaching 1.5 m in height; February-April (early May); flowers white, 6-8 cm wide when fully open, opening late afternoon, closing with daytime heat of the next morning. Widespread, dunes and sand flats; best developed on dunes including highest dunes. *Felger 98-72 & Evans.*

LOASACEAE - Stick Leaf Family

Mentzelia albicaulis Douglas ex Hook. White-stem blazingstar. Cool-season annuals; flowers small with uniformly bright-yellow petals. Dunes and especially in swales. *Felger 98 82 & Evans.*

FIG. 10. *Hyles lineata* eating *Lupinus arizonicus*, April 1998. Photo by Charles Hedgcock.

Fig. 11. *Nama hispidum* with *Schismus* above and *Pectocarya heterocarpa* below, April 1998. Photo by Charles Hedgcock.

Mentzelia multiflora (Nutt.) A.Gray. Blazingstar. Robust, cool-season annuals; flowers moderately large, yellow. Dunes and sometimes on sand flats. *Salywon & Shohet 558* (ASU); *Turner 92-2, 95-5.*

MALVACEAE Mallow Family

Malvella sagittifolia (A.Gray) Fryxell [*Sida lepidota* A.Gray var. *sagittifolia* A.Gray]. Narrowleaf mallow. Perennial herbs from deeply seated roots, spreading by rhizomes; growing and flowering with sufficient soil moisture any time of year except the coldest months. Open area of playa. *Reina-G. 96 210 & Van Devender; Salywon et al. 999* (ASU); *Turner 95-18.*

Sphaeralcea ambigua A.Gray subsp. **ambigua**. Desert globemallow. Perennial subshrubs; flowering various seasons, especially spring; flowers orange. Seasonally abundant at playa margins, and occasional on sand flats at northeast side of dunes. *Felger 98-21 et al.; Turner s.n, 19 Apr 1998.*

Sphaeralcea coulteri (S. Watson) A. Gray var. **coulteri**. Annual globemallow; *mal de ojo*. Non-seasonal annuals, generally growing with winter-spring rains, highly variable in size, several cm to 1.5 m tall; flowers orange. Seasonally abundant, lower dunes including swales, and sand flats. *Felger 98-75 & Evans; Turner 95-17.*

FIG. 12. *Hesperocallis undulata*, flowers ca. 6–7 cm long, April 1998; note the lower leaves in a basal rosette close to the sand. Photo by Charles Hedgcock.

MARTYNIACEAE - Devil's Claw Family

Proboscidea altheaefolia (Benth.) Decne. Devil's claw; *gato, uña de gato, torito*. **Fig. 13.** Perennial herbs from a single tuberous root, growing and flowering during warmer months; flowers showy, bright yellow with white and orange markings. Widely scattered; dunes, sand flats, and playa. *Felger 97-63 et al.; Felger 96-146 & Turner.*

MOLLUGINACEAE - Carpetweed Family

***Mollugo cerviana** (L.) Sér. Thread-stem carpetweed; Indian chickweed. Small, hot-weather annuals; flowers minute, green and whitish. Seasonally common on dunes. *Felger 97-62 et al., 97-81.*

NYCTAGINACEAE - Four-O'clock Family

Abronia villosa S. Watson var. **villosa**. Sand verbena. Cool-season annuals; flowers lavender-pink and fragrant. Widespread and often seasonally abundant on dunes and sand hummocks across the Mohawk Valley, often producing spectacular floral displays in spring. *Salywon et al. 996* (ASU); *Turner 95-15.*

Allionia incarnata L. Trailing windmills, trailing four o'clock. Non-seasonal annuals, mostly growing during warmer months, with trailing stems (elsewhere short lived perennials); violet-rose or magenta. Dunes and sand flats. *Felger 97-54 et al.; Felger 96-132 & Turner.*

Boerhavia erecta L. var. **intermedia** (M.E. Jones) Kearney & Peebles [*B. intermedia* M.E. Jones; *B. triqueta* S. Watson]. Spiderling. Hot-weather annuals; flowers white to pale pink. Sand flats. *Felger 97-75 et al.*

Boerhavia spicata Choisy [*B. spicata* var. *palmeri* S. Watson; *B. coulteri* (Hook. f.) S. Watson]. Hot-weather annuals; flowers white to pale pink. Sand flats and dunes; sometimes very common. The plants are often ravaged by white-lined sphinx moth caterpillars (*Hyles lineata*). *Felger 97-55 et al.; Felger 96 166 & Turner.*

Boerhavia wrightii A. Gray. Largebract spiderling. Hot-weather annuals; flowers pinkish white to pink. Sand flats, often localized in small depressions. *Felger 97-76 et al.*

ONAGRACEAE - Evening Primrose Family

Camissonia boothii (Douglas) P.H. Raven subsp. **condensata** (Munz) P.H. Raven. Woody bottle-washer. Cool-season annuals; flowers white. Skeletons may persistent for one year or more. Mostly in localized colonies on sand flats and occasionally at the playa edge. *Felger 98-92 & Evans; Felger 96-157 & Turner.*

Camissonia californica (Torr. & A. Gray) P.H. Raven. Cool-season annuals; flowers yellow, changing to orange and drying pink. Localized in dune swales and sometimes on sand flats, especially along small washes. *Felger 98-87 & Evans.*

Camissonia chamaenerioides (A. Gray) P.H. Raven. Longcapsule evening-primrose. Cool-season annuals; flowers pink. Sand flats, generally along small washes or in shallow depressions. This is the smallest-flowered evening primrose in the Sonoran Desert; the floral structure and modifications are characteristic of self-pollinated flowers. *Felger 98-100 & Evans.*

Camissonia claviformis (Torr. & Frém.) P.H. Raven subsp. **peeblesii** (Munz) P.H. Raven. Cool-season annuals. Corollas white to pink with maroon-brown inside the tube. Sand flats, lower dunes, dune swales and slopes. *Felger 98-14 et al.; Felger 98-94 & Evans; Turner 95-31.*

Camissonia claviformis subsp. **yumae** (P.H. Raven) P.H. Raven. Cool-season annuals. Corollas yellow with maroon-brown inside the tube. Sand flats near the dune field. *Felger 98-94 & Evans.* Although two subspecies occur in the area, they apparently do not occur intermixed and plants with intermediate features have not been found.

Oenothera deltoides Torr. & Frém. subsp. **deltoides**. Dune evening-primrose, white evening-primrose, devils' lantern. Cool-season annuals; flowers large and white. The dry skeletons persist for one or more years. Sand flats and dunes. Often common and showy. *Turner 95-8.*

Oenothera primiveris A. Gray subsp. **primiveris**. Yellow desert evening-primrose. Cool-season annuals; flowers large and yellow. The dry skeletons may persist for several years. Mostly lower dunes, also swales

Fig. 13. *Proboscidea altheaefolia*, dunes, August 1996. Photo by Charles Hedgcock.

and sand flats. *Felger 98-84 & Evans; Felger 96-158 & Turner.*

OROBANCHACEAE - Broomrape Family

Orobanche cooperi (A. Gray) A. Heller. Desert broomrape; *flor de tierra*. Cool-season annuals parasitic on *Ambrosia* spp.; stems thick and succulent; flowers purple and white, the throat often marked with yellow. Although the plants may appear perennial because of their robust habit, they are apparently annuals (George Yatskievych, pers. comm.). Sand flats. *Goldberg 77-91; Turner s.n., 2 May 1998.*

PAPAVERACEAE - Poppy Family

Argemone gracilenta Greene. Sonoran pricklypoppy, fried-egg poppy; *cardo*. Short-lived perennials to 80+ cm tall, or probably often facultative annuals in the flora region; flowering late spring and in nearby areas sometimes sporadically through the summer; flowers large, with white petals and numerous yellow stamens. Lower dunes and dune swales, scattered and seldom common. *Felger 98-77 & Evans.*

Eschscholzia glyptosperma Greene. Gold poppy. Cool-season annuals. Locally common during years of exceptional winter-spring rain; flowers yellow-orange. Sand flats, especially near the northern and eastern part of the dune field. *Felger 98-88 & Evans; Salywon et al. 982* (ASU); *Turner 95-23.*

Eschscholzia minutiflora S. Watson. Little gold-poppy. Cool-season annuals; flowers yellow-orange. Dunes and locally on sand flats. *Turner 95-33.*

PLANTAGINACEAE - Plantain Family

Plantago ovata Forssk. [*P. insularis* Eastw., not *P. insularis* (Grenier & Godron) Nyman; *P. fastigiata* E. Morris; *P. insularis* var. *fastigiata* (E. Morris) Jeps.]. Woolly plantain, Indian-wheat; *pastora*. Winter-spring ephemerals, highly variable in size depending on soil moisture; flowers straw-colored. Widespread across dunes and sand flats, but especially lower dunes and swales, and sometimes on the playa. *Felger 98-1 et al.*; *Goldberg 11 88*; *Salywon et al. 998* (ASU); *Turner 95-19*.

POACEAE (GRAMINEAE) Grass Family

Aristida adscensionis L. Sixweeks threeawn; *zacate tres barbas*. Non-seasonal annuals. Sand flats. *Felger 96-145 & Turner*.

Aristida californica Thurb. var. **californica**. California threeawn; *tres barbas de california*. Tufted perennials, also flowering in first season during summer. Widespread, sand flats and especially common on dunes. *Felger 98-10 et al.*; *Felger 96-142 & Turner, 96-167, 96-170*.

Bouteloua aristidoides (Kunth) Griseb. Sixweeks needle grama; *aceitilla, navajita*. Summer annuals. Sand flats and dunes; widespread and common. *Felger 97 80 et al., 97 67*; *Felger 96 140 & Turner*.

Bouteloua barbata Lag. Six weeks grama; *navajita, zacate liebrero*. Summer annuals. Sand flats and dunes. *Felger 97-68 et al.*; *Felger 96 131 & Turner, 96-131*.

Festuca octoflora Walter [*Vulpia octoflora* (Walter) Rydb.; *F. octoflora* var. *hirtella* Piper]. Sixweeks fescue, eight-flowered fescue. Cool season annuals; diminutive grass. Sand flats, mostly beneath shrubs and in small depressions at the northeast side of the dune field. *Felger 98-97 & Evans*.

Muhlenbergia microsperma (DC.) Trin Littleseed muhly; *liendrilla chica*. Non-seasonal annuals. Generally beneath shrubs in small washes or depressions in sand flats. *Felger 98-18 et al.*

Panicum alatum Zuloaga & Morrone var. **minus** (Andersson) Zuloaga & Morrone. Summer annuals. Shallow depression in sand flats at edge of playa. *Felger 98-8 et al.* This species is indistinguishable from the common and widespread *P. hirticaule* except for consistent spikelet characters. In western Sonora and southwestern Arizona *P. alatum* has a limited and localized distribution, characteristically in playas and similar habitats with temporary standing water and clayish soils, while *P. hirticaule* is widespread and common in many habitats throughout the region (Felger 2000). They do not seem to occur together.

Pleuraphis rigida Thurb. [*Hilaria rigida* (Thurb.) Benth. ex Scribn.]. Big galleta; *galleta grande, toboso*. Large, tufted or bushy perennials. Widespread and abundant, dunes and sand flats. *Felger 96 137 & Turner*.

***Schismus arabicus** Nees. Arabian schismus. Cool-season annuals. Widespread and seasonally abundant on sand flats and dunes, and especially common on dune slopes and swales. The plants at first grow close to the ground, apparently preventing the growth of native ephemerals (see Felger 2000). *Turner 95-11*.

POLEMONIACEAE - Phlox Family

Eriastrum diffusum (A. Gray) H. Mason. Cool-season annuals; flowers pale blue. Dunes and sand flats. *Felger 98-55 & Evans*.

Eriastrum eremicum (Jeps.) H. Mason. Cool-season annuals; flowers dark blue. Sand flats. This is the southwestern record for this species, and the only plant in the Mohawk flora not in the Gran Desierto or near the Pinta Sands or Yuma Dunes. *Burgess 5059*; *Turner 95-32*.

Linanthus bigelovii (A. Gray) Greene [*Gilia bigelovii* A. Gray, 1870; *Gilia jonesii* A. Gray, 1886; *Linanthus bigelovii* var. *jonesii* (A. Gray) Brand; *L. jonesii* (A. Gray) Greene]. Cool-season annuals. Flowers white, nocturnal, opening at or near dusk and powerfully sweet-fragrant, sometime nauseously sweet, and closing before sunrise. Dunes including swales and sand flats. *Bowers 2993*; *Felger 98 54 & Evans*; *Reichenbacher 273*.

Linanthus jonesii is distinguished by glandular-stipitate calyces (sometimes quite densely so) and seeds constricted near the middle (appearing "pinched off"), whereas *L. bigelovii* sensu stricto is distinguished by glabrous

calyces and a bladdery, ellipsoid seed. However, in southwestern Arizona the variation seems continuous, the characters do not seem correlated with each other, there appears to be no discernable correlation with habitat or geography, and they do not seem to be distinct taxa.

Loeseliastrum schottii (Torr.) Timbrook [*Langloisia schottii* (Torr.) Greene]. Winter-spring annuals. Scattered, mostly in swales and sand flats, sometimes extending to higher dunes, seldom common. *Felger 98-53 & Evans; Goldberg 77-83; Turner 95-34.*

POLYGONACEAE Buckwheat Family

Chorizanthe brevicornu Torr. subsp. **brevicornu**. Brittle spineflower, short-horn spineflower. Cool-season annuals; flowers white and minute. Dunes, especially swales, dune slopes, and lower dunes; also on sand flats. *Felger 98-81 & Evans.*

Chorizanthe rigida (Torr.) Torr. & A. Gray. Rigid spineflower. Cool-season annuals; the dry skeletons persistent for several years; flowers white, minute and cryptic. Common and widespread on sand flats. *Felger 98-9 et al.; Felger 98-89 & Evans; Reichenbacher 271.*

Eriogonum trichopes Torr. var. **trichopes**. Little trumpet. Cool-season annuals, occasionally surviving the summer; flowers yellow. Dunes and sand flats. *Felger 98-57 & Evans; Salywon et al. 989* (ASU).

Nemacaulis denudata Nutt. var. **gracilis** Goodman & L.D. Benson. Woolly heads. Cool season annuals; Flowers minute, yellow, surrounded by yellow-green to white and pink woolly bracts. Mostly in dune swales, also lower to higher dunes. *Felger 98 13 & Evans; Salywon et al. 990* (ASU).

RESEDACEAE - Mignonette Family

Oligomeris linifolia (Vahl) J.F. Macbr. Desert cambess, slenderleaf cambess. Non-seasonal annuals; flowers inconspicuous, white and green. Playa, sand flats, and lower dunes. *Turner 95-20.*

SALICACEAE - Willow Family

Populus fremontii S. Watson subsp. **fremontii**. Cottonwood; *alamo*. Several saplings along the southern edge of the playa. Apparently they grew during the El Niño year of 1992-1993, and were still living by end of April 1994, having reached 2-2.5 m tall, but perished by the end of 1994. *Felger 96-153 & Turner; Phil Rosen,* 24 Apr 1994, photo.

SIMAROUBACEAE - Quassia Family

Castela emoryi (A. Gray) Moran & Felger [*Holacantha emoryi* A. Gray]. Crucifixion thorn; *corona de cristo*. Shrubs 2-3 m tall; May-July; flowers cream-yellow to pink; fruits densely clustered and persistent. Scattered on sand flats, and also lowermost dunes surrounding the playa. *Felger 96-162 & Turner; Reina-G. 96-216 & Van Devender.*

SOLANACEAE - Nightshade Family

Datura discolor Bernh. Poisonous nightshade, desert thorn-apple; *toloache*. Non-seasonal annuals, the plants frost-sensitive; flowers 8-17 cm long, corollas white with a purple flush in the throat, nocturnal and fragrant. Sand flats and probably on dunes. This is the largest-flowered plant in the region. *Felger & Turner*, 25 Sep 1996, observation.

Lycium parishii A. Gray var. **parishii**. Parish wolfberry; *salicieso*. Shrubs; reproductive at various seasons, especially late winter and early spring; corollas lavender. Washes in sand flats near north end of dunes. *Felger 98-20 et al.*

Physalis lobata Torr. [*Quincula lobata* (Torr.) Raf.]. Annual or perennial herbs with a deep tap root; flowers lavender, after sufficient rains at various seasons. Locally at the playa margins. *Felger 98-51 & Evans; Turner 95-29.*

TAMARICACEAE - Tamarisk Family

***Tamarix ramosissima** Ledeb. [*T. chinensis* of American authors, not Lour.?]. Saltcedar, tamarisk; *salado, pino salado*. One shrub at the southwest edge of the playa, first seen May 1995, and by June 1996 it had perished from drought. *Felger & Turner*, 25 Sep 1996, observation.

VISCACEAE - Mistletoe Family

Phoradendron californicum Nutt. Desert

mistletoe; *tóji*. Epiphytic perennial parasites; flowers small, green or yellow, at various seasons, especially January and February; highly fragrant and attracting honeybees and other insects; fruiting in same season. On widely scattered mesquite trees on sand flats. *Felger & Turner*, 24 Sep 1996, observation.

ZYGOPHYLLACEAE Caltrop Family

Kallstroemia californica (S. Watson) Vail. California caltrop; *mal de ojo*. Hot-weather annuals; flowers yellow to yellow-orange. Sand flats and dunes. *Felger 97-58 et al.; Felger 96 129 & Turner, 96-133, 96 160.*

Larrea divaricata Cav. subsp. **tridentata** (Sessé & Moç. ex DC.) Felger & C.H. Lowe [*L. tridentata* (Sessé & Moc. ex DC.) Cov.]. Creosotebush; *hediondilla, gobernadora*. Long-lived shrubs ca. 1–2 m tall with very hard wood; flowers yellow, various seasons. Dominant shrub or "canopy" across most of the sand flats and valley floor surrounding the dunes, and extending onto lower dunes and dune swales.

ACKNOWLEDGMENTS

For financial support we thank the Wallace Research Foundation, and the 56th Range Management Office of Luke Air Force Base for funding this work under Contract FO260497MS130 and under the Department of Defense Legacy Resource Management Program (Project 95-1009). We thank Bill Broyles, Luke Evans, Julia Fonseca, Scotty Johnson, Cecil Schwalbe, Gerald Turner, Louise Turner, and Peter Warren for generous assistance and Charles Hedgcock (www.charleshedgcock.com) and Thomas R. Jones for supplying photos. James Henrickson, Wendy Hodgson, and John Anderson provided significant reviews. Phil Jenkins and Michael Chamberland of the University of Arizona herbarium greatly facilitated our work, and Andrew Salywon and Tom Van Devender shared significant information.

ABSTRACT

Big Branch Marsh National Wildlife Refuge is a U.S. Department of the Interior Fish and Wildlife Service complex comprising approximately 5,870 ha (14,500 acres). A floristic survey was conducted to provide refuge staff with a checklist of vascular plant species, along with species abundance and habitat preference when one existed. Collecting trips made to the refuge from August 1999 through April 2002 yielded 563 infraspecific taxa of vascular plants representing 117 families and 309 gen era. The four largest families are Poaceae, Cyperaceae, Asteraceae, and Fabaceae. Descriptions of salient plant communities are provided.

RESUMEN

El Refugio Nacional de Vida Salvaje de Big Branch Marsh es un complejo del Servicio del Departamento de Pesca Interior y Vida Salvaje de los Estados Unidos que tiene aproximadamente 5,870 ha (14,500 acres). Se realizó un estudio florístico para ofrecer al personal del Refugio un listado de las especies de plantas vasculares, junto con abundancia de especies y preferencia de hábitat cuando existía. Los viajes de recolección al refugio de agosto de 1999 a abril de 2002 dieron 563 taxa infraespecíficos de plantas vasculares pertenecientes a 117 familias y 309 géneros. Las cuatro familias más grandes son Poaceae, Cyperaceae, Asteraceae, y Fabaceae. Se ofrecen descripciones de las comunidades vegetales más importantes.

INTRODUCTION

The National Wildlife Refuge System is administered by the U.S. Department of the Interior, Fish and Wildlife Service. The mission of the Refuge System is to administer a national network of lands and waters for the conservation, management, and where appropriate, restoration of the fish, wildlife, and plant resources and their habitats within the United States for the benefit of present and future generations of Americans. Big Branch Marsh National Wildlife Refuge (BBMNWR), which was established in 1994, is one of over 530 refuges throughout the country and one of 22 refuges in Louisiana. At the onset of this survey, BBMNWR was the last large undeveloped area on the rapidly develop-

SIDA 20(3): 1189–1216. 2003

ing north shore of Lake Pontchartrain. The management objectives of BBMNWR are to provide (1) habitat for a natural diversity of wildlife associated with Big Branch Marsh, (2) wintering habitat for migratory waterfowl, (3) nesting habitat for wood ducks, (4) habitat for non-game migratory birds, and (5) opportunities for public outdoor recreation.

The forested areas of BBMNWR are primarily managed for the federally listed endangered red-cockaded woodpecker (*Picoides borealis*). About 12 clusters of these birds are currently active on the refuge. Red-cockaded woodpeckers build their nests in live pine trees and require an open understory necessitating prescribed burns by refuge personnel every 3—4 years. Refuge marshes are also burned every 2—3 years to improve habitat for wading birds and migratory waterfowl. The understanding and management of any animal community demands (1) defining the plant communities in which they live, (2) defining the surrounding plant communities in which they move in and out of, and (3) identifying the plant species utilized for food, cover, and nesting. As is the case with most National Wildlife Refuges, no detailed floristic study had been conducted on BBMNWR. Therefore, a floristic survey was conducted to provide refuge staff with a checklist of vascular plant species and information on species abundance and habitat preference.

Study Area

BBMNWR is located between 30° 15' 35" and 30° 19' 54"N latitude and 89° 54' 37" and 90° 00' 53"W longitude in St. Tammany Parish, Louisiana (Fig. 1). The refuge lies within the Coastal Plain Province of the Atlantic Plain Division (Fenneman 1928). The refuge headquarters and visitor center are located W of Hwy. 434 at about 30° 19' 17"N, 89° 56' 14"W in the town of Lacombe. Several minor tributaries border and traverse the refuge holdings. The refuge is bounded to the W by Cane Bayou, bisected by Bayou Lacombe and its tributaries, and traversed by Bayou Liberty, Bayou Bonfouca, Cypress Bayou, Bayou due Chien, their tributaries, and other small unnamed tributaries. The most notable refuge boundary is Lake Pontchartrain, a shallow, flat-bottomed fresh to brackish water body with an average depth of approximately 3-m (Steinmayer 1939). The refuge lies entirely within its floodplain between the 0 and 5 foot contour lines. Lake salinity normally ranges from 1 to 10 $^{0}/_{00}$. In recent drought years, however, salinity has reached 20 $^{0}/_{00}$ (pers. obs.). The climate in St. Tammany Parish is temperate with an average winter temperature of 12° C, and a daily minimum average of 5° C. Average summer temperature is 27° C, and the average daily high is 33° C (Trahan et al. 1990). Total annual precipitation is 155 cm, average relative humidity during the day is 60% and is 90% at dawn (Trahan et al. 1990).

The approximately 5870 ha (14,500 acre) refuge is described by refuge staff as predominately a mixture of intermediate and fresh marsh, pine flatwoods,

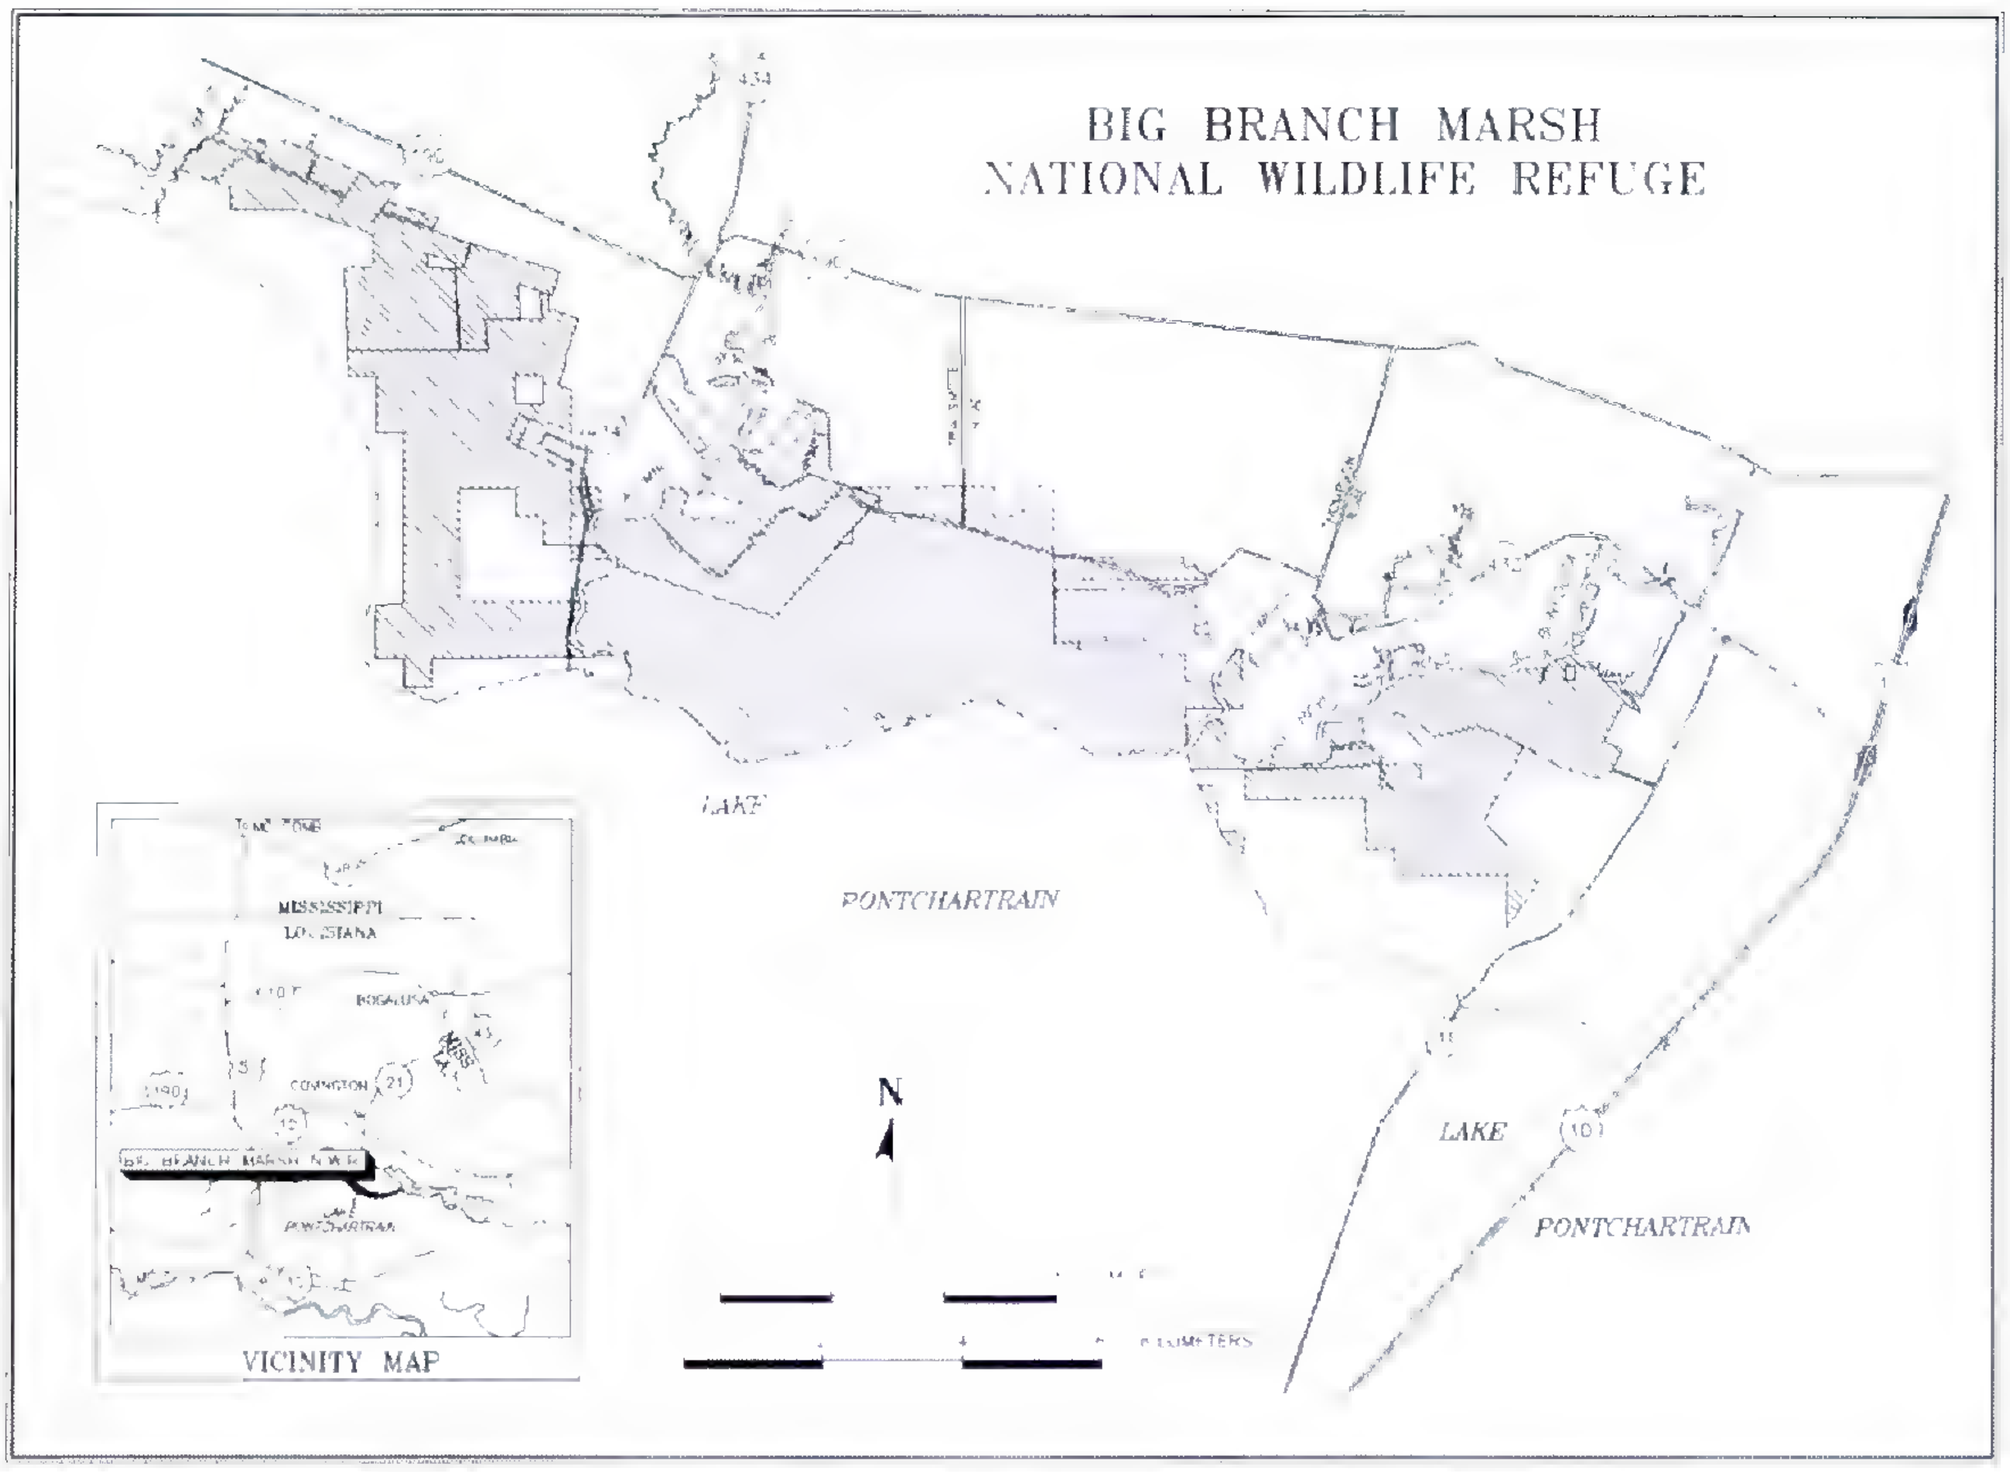

FIG. 1. Map showing location and boundaries of Big Branch Marsh NWR during survey.

pine islands, pine ridges, and hardwood hammocks. The forests in the area were almost completely clear cut early in the 20th century (Ellis 1981). Most of the evergreen forests in the region were dominated by longleaf pine (*Pinus palustris* Mill.) prior to modern silviculture operations and fire suppression. Currently, either slash pine (*P. elliottii* Engelm. var. *elliottii*), loblolly pine (*P. taeda* L.), or longleaf pine are dominant or co-dominant in refuge evergreen forests.

The most notable physiognomic feature of the refuge is a distinct line of demarcation where marsh meets pine flatwoods. The prairie terrace is comprised of consolidated sediments formed during the Pleistocene resulting from rising and falling sea levels and changes in the course of the Mississippi River (Fisk & McFarlan 1955; Saucier 1963). The forested areas of the refuge overlay the terrace. The entire refuge area is subsiding, but the effect is most noticeable in the existing marshes. In some locations, the marsh-forest edge is lined with dead stands of pine trees that have been inundated with brackish lake water.

METHODS

Topographical maps and color infrared aerial photos were examined and interpreted to locate different habitats and plan fieldwork. Collecting trips were made to the refuge from August 1999 through April 2002. The objectives of each trip

were the collection of voucher specimens, careful notation of apparent habitat preference, and estimates of abundance of each species. Voucher specimens are housed at the Tulane University Herbarium (NO). Duplicate specimens, when available, were provided to the staff of BBMNWR. Identifications were made using regional manuals including Allen (1992), Correll and Johnston (1970), Cronquist (1980), Gandhi and Thomas (1989), Godfrey (1988), Godfrey and Wooten (1979, 1981), Gould (1975), Isely (1990), and Radford et al. (1968).

RESULTS

Floristics

Collecting trips yielded 563 infraspecific taxa of vascular plants representing 117 families and 309 genera (Table 1). The four families containing the most infraspecific taxa (in parenthesis) are Poaceae (94 spp.), Cyperaceae (64 spp.), Asteraceae (61 spp.), and Fabaceae (25 spp.). One species, *Imperata brasiliensis* (L.) Beauv., is listed by the U.S. Department of Agriculture as a noxious weed. Non native species accounted for 12.8 % of the total species. No Federally-listed threatened or endangered plant species were found.

Plant Communities

The distribution and composition of plant communities on the refuge appear most influenced by the salinity and tidal activity of Lake Pontchartrain and larger tributaries. Other major influences are topography, geology, soil type, weather, historic and ongoing disturbances, and management regimes. Plant communities were described to indicate diversity and uniqueness and to aid in future management practices. The following plant communities were defined by comparing field observations of dominant woody and herbaceous species and hydrological regimes to The Nature Conservancy's *International Classification of Ecological Communities: Terrestrial Vegetation of the Southeastern United States* (ICEC) (Weakly et al. 1998). Plant community names of the ICEC hierarchy are used. Following the ICEC alliance plant community name, the name used by refuge staff is listed in parenthesis. Communities at the alliance and association levels are reported. These are the two lowest communities in the hierarchy of classification listed in the ICEC and are based on floristics. Associations within alliances are discussed under the alliances. Conservation ranks of G3 or lower are reported (G1–critically imperiled globally; G2–imperiled globally; G3–rare or uncommon globally). A myriad of disturbed sites such as borrow pits, ditches, roads, spoil areas, logging ruts, and mowed rights-of-way may occur in each alliance or association, typically supporting a variety of ruderal, wetland, and aquatic species.

Forest Alliances

***Fagus grandifolia–Magnolia grandiflora* Forest Alliance (Beech-Magnolia Woods).** A single representative association of this alliance was found on BBMNWR,

TABLE 1. Statistical taxonomic summary of the vascular flora of Big Branch Marsh NWR.

				Infraspecific Taxa	
Class	**Families**	**Genera**	**Native**	**Introduced**	**Total**
Lycopodiopsida	1	1	1	_	1
Isoëtopsida	1	1	1	_	1
Polypodiopsida	9	9	8	2	10
Pinopsida	2	2	6	_	6
Liliopsida	24	85	194	21	215
Magnoliopsida	80	211	281	49	330
Totals	117	309	491	72	563

the *Fagus grandifolia* Ehrh. (American beech)–*Magnolia grandiflora* L. (southern magnolia)–*Quercus nigra* L. (water oak)–*Pinus glabra* Walt. (spruce pine)/*Viburnum dentatum* L. (southern arrow-wood) Association. This association occurs on uplands fringed by the marshes adjacent to Cane Bayou. Common trees in the subcanopy include *Carpinus caroliniana* Walt. (coastal ironwood), *Carya glabra* (Mill.) Sweet. (pignut hickory), and *Quercus falcata* Michx. var. *falcata* (southern red oak). Common shrubs are *Aesculus pavia* L. (red buckeye), *Callicarpa americana* L. (beauty berry), *Erythrina herbacea* L. (coralbean), *Halesia diptera* Ellis. (two-wing silverbell), *Symplocos tinctoria* (L.) L'Her. (sweetleaf), and *Vaccinium arboreum* Marsh. (farkleberry). Southern arrow-wood is apparently absent in this association at BBMNWR. Common herbaceous species include *Chasmanthium laxum* (L.) Yates var. *laxum* (slender spikegrass), *Carex* spp. (caric-sedges), and *Panicum* spp. (panic-grasses). This association is easily viewed at the Cane Bayou access area.

***Nyssa aquatica*–(*Taxodium distichum*) Semipermanently Flooded Forest Alliance (Floodplain Swamps).** A single representative association of this alliance was found on BBMNWR, the *Nyssa aquatica* L. (swamp tupelo)–*Nyssa biflora* Walt. (swamp blackgum) Forest Association. This association occurs along a small, meandering, unnamed tributary SE of Bremermann Road near the W boundary of the refuge (Fig. 2A). Common trees in the subcanopy include *Acer rubrum* L. var. *drummondii* (Hook. & Arn. ex Nutt.) Sarg. (swamp red maple) and *Fraxinus caroliniana* Mill. (water ash). Common shrubs are *Cephalanthus occidentalis* L. (buttonbush), *Cornus foemina* Mill. (gray dogwood), *Itea virginica* L. (Virginia-willow), and *Planera aquatica* (Walt.) J.F. Gmel. (planertree). Common herbaceous species occurring in soils saturated for long duration include *Echinodorus cordifolius* (L.) Griseb. (heart-leaf burhead), *Iris virginica* L. (southern blue flag), *Panicum gymnocarpon* Ell. (swamp panicgrass), *Polygonum densiflorum* Meisn. (denseflower knotweed), and *Saururus cernuus* L. (lizard's tail). Woody and herbaceous species occuring on small hum-

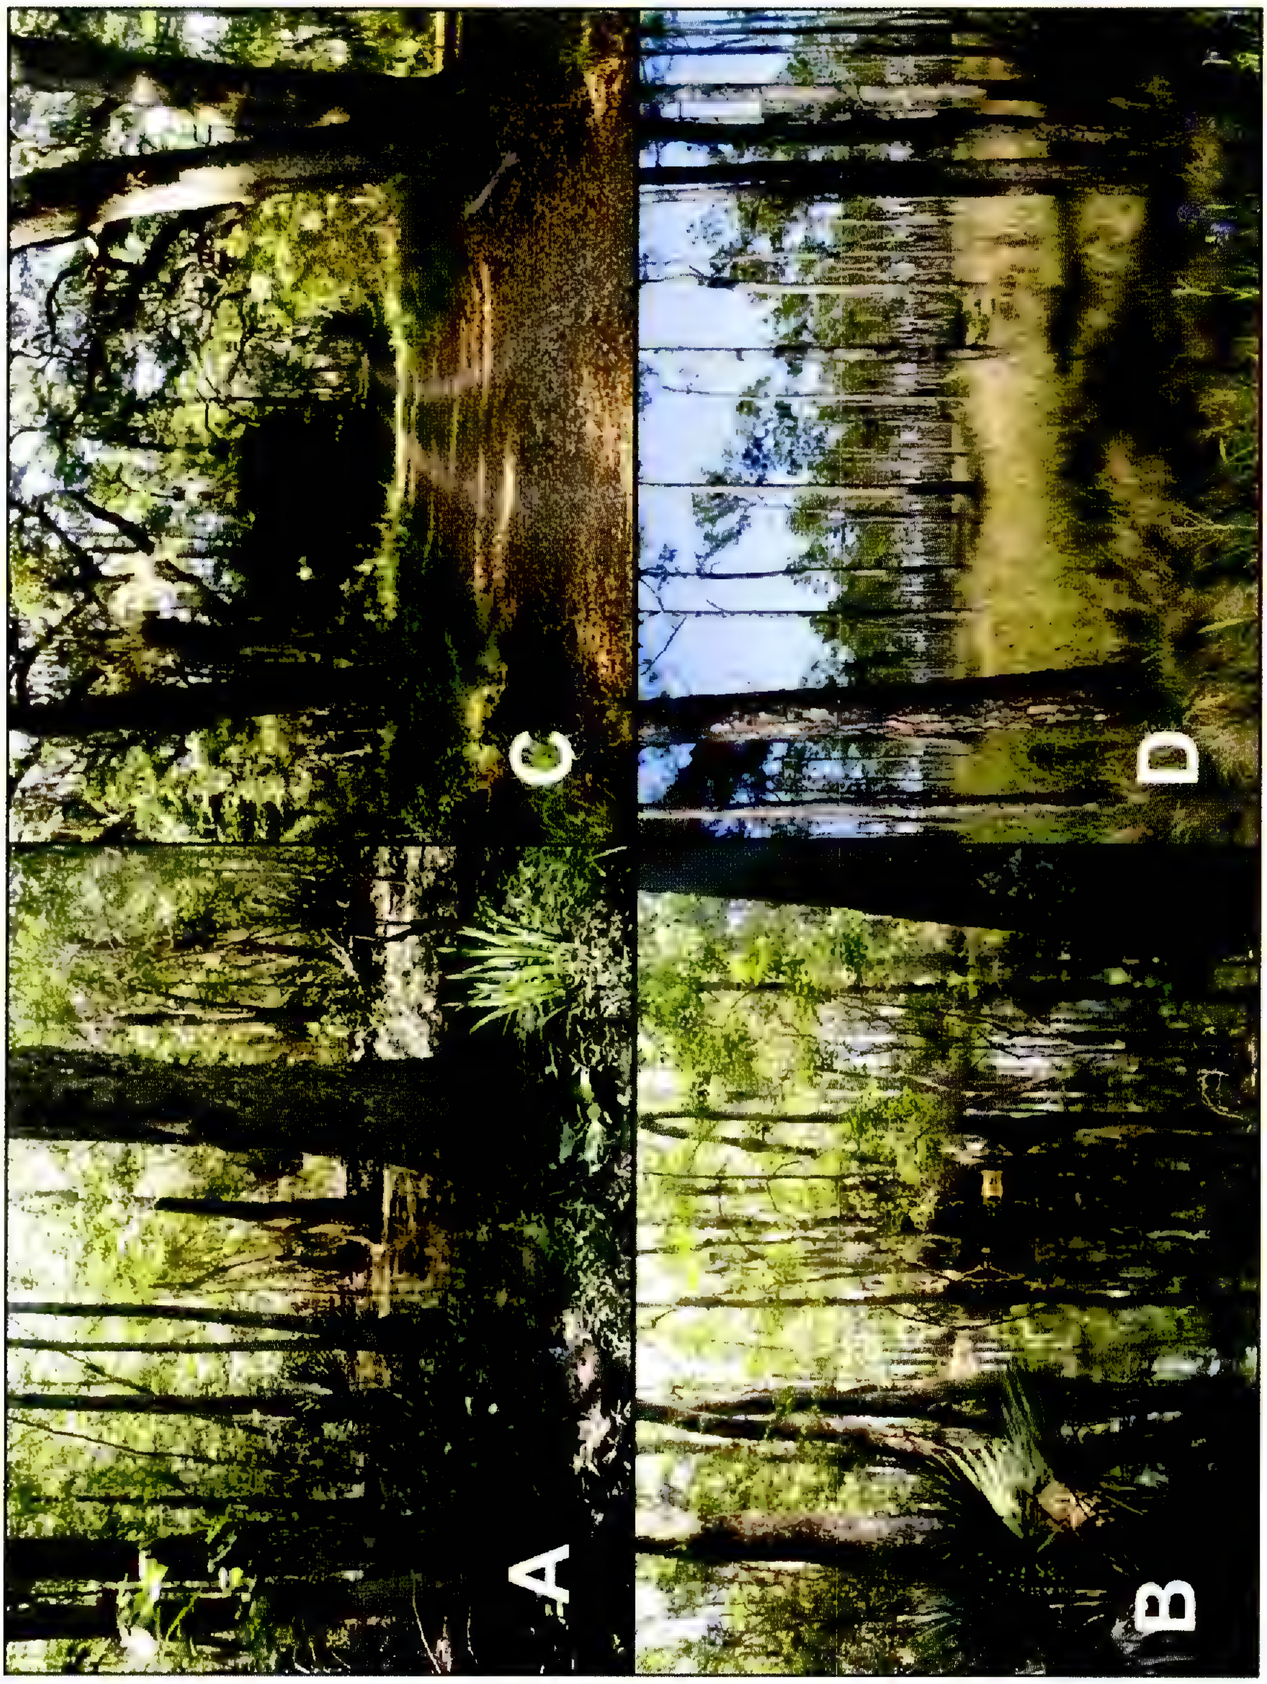

Fig. 2. Plant communities of Big Branch Marsh NWR. **A.** Floodplain swamp along unnamed tributary; trees are *Nyssa aquatica* and *N. biflora*. **B.** *Nyssa biflora* swamp along Boy Scout Road also dominated by *Sabal minor*, *Crataegus opaca*, and *Sapium sebeferum*. **C.** Example of hardwood hammock along Boy Scout Road; trees are *Quercus virginiana*. **D.** Pine flatwoods showing overstory of *Pinus elliottii* var. *elliottii* and lush undergrowth of *Spartina patens* and *Panicum virgatum*.

mocks, tree bases, and other higher places within this forest association include *Carex debilis* Michx. var. *debilis*. (weak caric-sedge), *C. lonchocarpa* Willd. (spear-fruit caric-sedge), *C. louisianica* L.H. Bailey. (Louisiana caric-sedge), *C. reniformis* (L.H. Bailey) Small (kidney-fruit caric-sedge), *C. tribuloides* Wahl. var. *sangamonensis* Clokey. (sangamon blunt broom caric-sedge), *Hypoxis curtissii* Rose (Curtiss' yellow stargrass), *Ilex verticillata* (L.) Gray (winterberry), and *Rhododendron viscosum* (L.) Torr. (swamp azalea).

***Nyssa biflora* Pond Seasonally Flooded Forest Alliance (Gum Swamps).** A single unnamed forest association was found within the swamp blackgum Pond Seasonally Flooded Forest Alliance. This unnamed association would be called a swamp blackgum/*Crataegus opaca* Hook. & Arn. (mayhaw) Pond Seasonally Flooded Forest Association. The canopy of this association is dominated by swamp blackgum with the mid-story dominated by mayhaw, and is rare at BBMNWR. This association is a ponded wetland within an upland forest and should have a conservation rank of G3. Another woody species present is *Sapium sebiferum* (L.) Roxb. (Chinese tallow-tree). *Lemna minor* L. (lesser duckweed) commonly forms a dense mat on the water's surface. Characteristic herbaceous species on pond margins can include *Carex gigantea* Rudge. (giant caric-sedge), *C. glaucescens* Ell. (southern waxy sedge), *C. joorii* L. H. Bailey (cypress swamp sedge), southern blue flag, *Sabal minor* (Jacq.) Pers. (dwarf palmetto), *Spiranthes odorata* (Nutt.) Lindl. (fragrant ladies'-tresses), and *Woodwardia areolata* (L.) Moore. (netted chainfern). During times of drought or low water, exposed soils are quickly colonized with species such as *Eragrostis hypnoides* (Lam.) B.S.P. (creeping lovegrass), *Heliotropium indicum* L. (Indian heliotrope), and *Lindernia dubia* (L.) Penn. (false pimpernel). An example of this alliance can be viewed S of Boy Scout Road, near its terminus at Bayou Lacombe (Fig. 2B).

***Pinus taeda* Planted Forest Alliance (Pine Savanna)**. A *Pinus taeda* L. (loblolly pine) Planted Forest Association borders the refuge boundaries N of Bayou Paquet Road, just E of its intersection with Transmitter Road. Clearcut portions of this association have developed into herbaceous bogs that overlap into clearings and fire-brakes on refuge boundaries.

***Pinus taeda* Forest Alliance (Mixed Woods)**. This alliance serves as a placeholder for refuge successional forests dominated by loblolly pine. We did not assign an association name due to the great floristic variation in this alliance. However, quanitative analysis would surely yield numerous associations. Other canopy dominates include *Liquidambar styraciflua* L. (sweetgum), *Nyssa sylvatica* Marsh. (blackgum), *Quercus similis* Ashe. (swamp post oak), *Q. falcata* Michx. var. *pagodifolia* Ell. (cherrybark oak), and southern red oak. Shrub and herbaceous strata are well developed and species composition varies with microtopography and hydrologic regime. See the annotated checklist for other species found in this alliance.

***Quercus laurifolia*–*Nyssa biflora* Saturated Forest Alliance (Forest Swales).** This alliance best describes associations encountered in forest swales and drainages within mixed woods. The swamp blackgum–*Quercus laurifolia* (diamondleaf oak)–*Quercus phellos* (willow oak) / dwarf palmetto Forest Association (G3) is common in the refuge. Other common woody species include swamp red maple, mayhaw, and water oak. Herbaceous vegetation is often sparse or absent under dense canopies. However, in clearings and forest openings herbaceous species include Louisiana caric-sedge, southern blue flag, *Leersia lenticularis* Michx. (catchfly grass), *Rhynchospora corniculata* (Lam.) Gray. (shortbristle horned beaksedge), lizard's tail, and netted chainfern.

***Quercus* (*michauxii*, *falcata* var. *pagodifolia*, *shumardii*)–*Liquidambar styraciflua* Temporarily Flooded Forest Alliance (Oak-Hickory Ridge).** This alliance best describes unnamed associations that occupy the forested portions of BBMNWR dominated by *Quercus michauxii* Nutt. (swamp chestnut oak) and sweetgum. *Quercus shumardii* Buckl. (shumard oak) is absent on BBMNWR. A community dominated by swamp chestnut oak, sweetgum, pignut hickory, and swamp post oak exists on a broad ridge that spans NW of a small day-use parking area at the intersection of Bertha Lane and Lucille Road. This association also occurs as a transition or fringe allied with other forest associations.

***Quercus virginiana* Temporarily Flooded Forest Alliance (Hardwood Hammocks).** A single association was placed under this alliance, a *Quercus virginiana* Mill. (live oak) / (dwarf palmetto, *Serenoa repens* (Bartram) J. K. Small [saw palmetto]) Forest Association. At the terminus of Boy Scout Road, a live oak forest occurs on old archeological features, and grades into low lying areas that are temporarily flooded during storm events (Fig. 2C). The shrub stratum is poorly developed with a few scattered dwarf palmetto. Herbaceous cover is sparse with slender spikegrass, and *Elephantopus* spp. (elephant's-foot). Saw palmetto is absent at BBMNWR.

Woodland Alliances

***Pinus elliottii* Saturated Temperate Woodland Alliance (Pine Flatwoods).** This alliance is represented by the *Pinus elliottii* Engelm. var. *elliottii* (slash pine)/ *Spartina patens* (Ait.) Muhl. (saltmeadow cordgrass)–*Juncus roemerianus* Scheele. (black needlerush)–(*Panicum virgatum* L. [switchgrass]) Woodland Association (G3). These flat, low-lying wetlands adjacent to the refuge marshes have an open to sometimes dense canopy of slash pine. Subcanopy and shrub layers are usually absent, though species such as *Morella cerifera* (L.) Small (wax myrtle), *Iva frutescens* L. (maritime marsh-elder), dwarf palmetto, *Baccharis halimifolia* L. (groundsel-tree), *B. angustifolia* Michx. (saltwater false-willow), and Chinese tallow tree may be present, particularly in areas not subjected to fire. The herbaceous stratum is dense and is dominated by saltmeadow

cordgrass, switchgrass, *Solidago sempervirens* L. (seaside goldenrod), and *Euthamia leptocephala* (Torr. & Gray) Greene. (bushy fragrant-goldenrod). Other conspicuous though less common herbs include *Symphyotrichum* spp., *Eryngium yuccifolium* Michx. (rattlesnake master), *Oxypolis filiformis* (Walt.) Britt. (leafless cowbane), and *Asclepias lanceolata* Walt. (lance-leaf milkweed). This association is not inundated by normal daily tides, but receives inundation during storm events. Water tables are high due to landscape position and soil texture. Within this association are a few scattered stands of *Cladium mariscus* (L.) Pohl subsp. *jamaicense* (Crantz) Kükenth. (sawgrass). The best place to observe this association is along Boy Scout Road (Fig. 2D).

***Pinus palustris–Pinus* (*echinata*, *taeda*) Woodland Alliance (Longleaf Pine Savanna).** A *Pinus palustris* Mill. (longleaf pine)–*Pinus* (*echinata* [shortleaf pine], loblolly pine) / *Schizachyrium scoparium* (Michx.) Nash. (little bluestem) Woodland Association represents this alliance at BBMNWR. Subcanopy species include saplings of the nominal species and swamp post oak. Dominant shrubs are *Ilex vomitoria* Ait. (yaupon) and wax myrtle. Herbaceous cover is dense and is dominated by little bluestem, *Andropogon* spp., and *Aristida longespica* Poir. var. *geniculata* (Raf.) Fern. (plains threeawn). This forest occurs on mesic flats near Lake Pontchartrain that are periodically inundated by storm events. This community is somewhat inaccessible and located several miles from paved roads in the Salmen Tract in the city of Slidell. Near the end of the study, a prescribed burn management regime was initiated in this woodland alliance. This will undoubtedly alter the community composition.

Herbaceous Alliances

***Nymphaea odorata* Permanently Flooded Temperate Herbaceous Alliance (Sloughs).** This alliance is represented by a single association, the *Nymphea odorata* Ait. var. *odorata* (white water lily) Herbaceous Vegetation Association. This association occurs as semipermanently flooded sloughs, ditches, borrow ponds, and marsh ponds, usually within other communities. The best place to observe this association is from an interpretive station along Boy Scout Road near the parking area (Fig. 3A).

***Sagittaria lancifolia* Semipermanently Flooded Herbaceous Alliance (Fresh Marsh).** Two associations represent this alliance. The first is a *Sagittaria lancifolia* L. (lanceleaf arrowhead) Herbaceous Vegetation Association (G3). This shallow freshwater marsh is dominated by a monoculture of lanceleaf arrowhead and is best observed along Boy Scout Road (Fig. 3B). The second is an unnamed association that forms dense marsh fringes along Cane Bayou (Fig. 3C). This association, based on field observations, would be called a lanceleaf arrowhead–*Schoenoplectus tabernaemontani* (K.C. Gmel.) Palla (softstem bullrush)–*Schoenoplectus americanus* (Pers.) Volk. (olney threesquare) Herba-

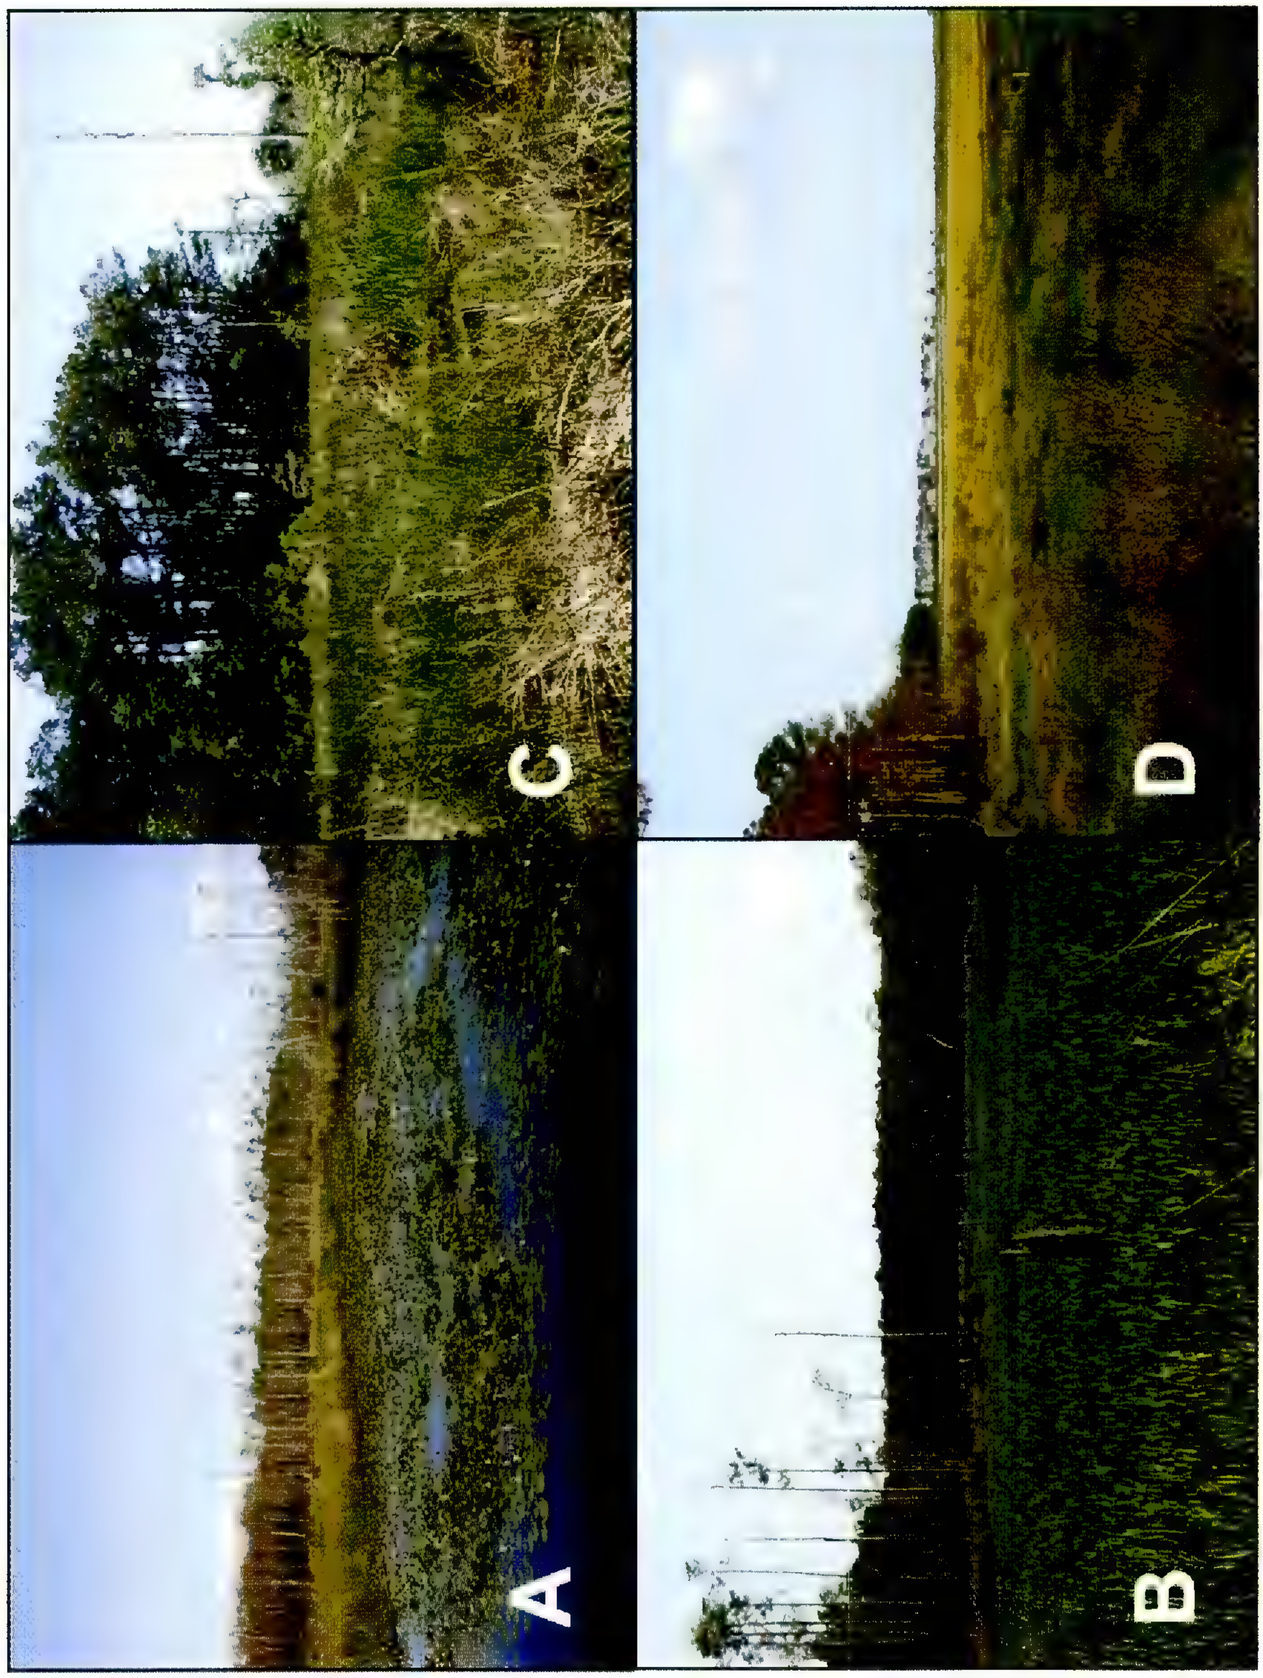

Fig. 3. Plant communities of Big Branch Marsh NWR. **A.** Slough along Boy Scout Road with *Nymphea odorata* var. *odorata* rimmed with dead pines that have succumbed to subsidence. **B.** Fresh marsh along Boy Scout Road dominated by *Sagittaria lancifolia* and adjacent pine flatwoods. **C.** Fresh marsh of *Schoenoplectus tabernaemontani*, *S. americanus*, and *Eleocharis palustris* adjacent to Bayou Cane. **D.** Sharp transition from intermediate marsh community to flatwoods.

ceous Vegetation Association with a proposed conservation rank of G3. Other common herbaceous species include *Eleocharis palustris* (L.) R. & S. (great plains spikerush), *Ptilimnium capillaceum* (Michx.) Raf. (thread-leaf mock bishop's-weed), and *Alternanthera philoxeroides* (Mart.) Griseb. (alligator weed). A few widely scattered *Taxodium ascendens* Brongn. (pond cypress) are present in this association.

***Spartina alterniflora* Tidal Herbaceous Alliance (Smooth Cordgrass Marsh).** The *Spartina alterniflora* Lois. (saltmarsh cordgrass) Louisianian Zone Herbaceous Vegetation Association occurs as monotypic bands of saltmarsh cordgrass along tidal streams, canals, and littoral zones on the shore of Lake Pontchartrain.

***Spartina patens*–(*Distichlis spicata*) Tidal Herbaceous Alliance (Intermediate Marsh).** The saltmeadow cordgrass–*Schoenoplectus* (olney threesquare, *pungens* [Vahl] Palla [common threesquare])–(*Distichlis spicata* (L.) Greene [saltgrass]) Herbaceous Vegetation Association (G3) inhabits the refuge marshes inundated by spring tides. *Bolboschoenus robustus* (Pursh) Soják (Alkali Bulrush) replaces olney threesquare and common threesquare as found elsewhere in marshy sites at BBMNWR. Other common herbaceous species include switch grass, *Eleocharis cellulosa* Torr. (Gulf Coast spikerush) and black needlerush. A band of shrubs including groundsel-tree and maritime marsh-elder can occur as a transition zone between this association and dryer communities or in small scattered thickets. The best place to observe this community is from the observation platform on Boy Scout Road (Fig. 3D).

***Vallisneria americana* Permanently Flooded–Tidal Herbaceous Alliance (Grass Beds).** A *Vallisneria americana* Michx. (American eelgrass) Estuarine Bayou Herbaceous Vegetation Association (G3) occurs along the shores of Bayou Bonfuca, several tidal canals, sloughs, and marsh ponds. Other aquatic plants common in this association include *Myriophyllum sibiricum* Kom. (siberian water-milfoil), *Ruppia maritima* L. (wigeongrass), and *Zannichellia palustris* L. (horned pondweed).

EXOTIC SPECIES OF CONCERN

The following non-native species are, or have the potential to become, serious and difficult to control weeds and may threaten the diversity of plant communities of BBMNWR. **Woody Species:** Chinese tallow-tree, a native of China and Japan, and a tenacious weed of the SE United States, was encountered in most of the refuge forests and woodlands. This species is not well established in these habitats, but should be monitored closely. *Ligustrum sinense* Lour. (common privet), a native of Europe, is well established and frequent in mixed woods and oak hickory forests. *Poncirus trifoliata* (L.) Raf. (trifoliate orange) is native to Asia. This species has escaped from cultivation near an old homesite at the ter-

minus of Boyscout Road and has become well established in hardwood hammocks. Armed with stout spines, this shrub forms inpenetrable thickets. Another native to Asia, *Rosa bracteata* J. Wendl. (Macartney rose), is occasional in mixed woods. **Woody and Herbaceous Vines:** *Lonicera japonica* Thunb. (Japanese honeysuckle) is a climbing vine that was occasionally encountered in oak hickory forests. A more troublesome herbaceous vine was *Lygodium japonicum* (Thunb.) Sw. (Japanese climbing fern), a native of Asia and the Austral Tropics. This vine was well established in mixed and beech magnolia woods. **Herbaceous Species:** *Alternanthera philoxeroides* (Mart.) Griseb. (alligator weed), native to Australia, was frequent in fresh marsh and ditches. *Colocasia esculenta* (L.) Schott (wild taro), a native to Asia, was restricted to roadside ditches SE of Bremermann Road near the W boundary of the refuge. *Imperata brasiliensis* (L.) Beauv. (Imperata) is Native to Tropical America and becoming well established along Boyscout Road and other nearby locations. Other grasses occasional to frequently abundant in disturbed areas with the potential to become a problem include *Paspalum dilatatum* Poir. (dallis-grass) and *Paspalum urvillei* Steud. (Vasey-grass), both native to South America, *Paspalum notatum* Flüggé. (bahia-grass) native to Latin America, and *Sorghum halepense* (L.) Pers. (Johnson-grass), native to the Mediterranean.

ANNOTATED CHECKLIST OF SPECIES

Plant names are arranged by class, and then listed alphabetically within class by family, genus, species, and infraspecific rank using the classification systems found in Cronquist (1981), Kartesz (1994), Jones et al. (1997), or more recent classifications found in monographs. Applicable synonymy for select species is provided when considered useful. Each taxon is followed by a brief description of its habitat type(s). Next is a subjective estimate of relative abundance using the following scheme: very rare–known from only a single locale with few individuals; rare–known from more than one locale, generally with small populations or one locale with numerous individuals; infrequent–not always in the stated community type(s), usually in small numbers; occasional–often in the community type(s), but rarely in large numbers; frequent–usually encountered in the community type(s), but not always in large numbers; and abundant–expected in the type, usually in large numbers. Collectors and collection numbers are David J. Rosen (DJR), James M. Joyner (JMJ), and Gary M. Couret (GMC). Non-native taxa are based on Thomas and Allen (1993, 1996, 1998) and indicated by an asterisk (*).

LYCOPODIOPSIDA

LYCOPODIACEAE

Lycopodiella alopecuroides (L.) R.Cranfill [*Lycopodium alopecuroides* L.], bogs, frequent, *DJR 1654.*

ISOËTOPSIDA

SELAGINELLACEAE

Selaginella apoda (L.) Spring, oak hickory ridge, occasional, *DJR 969.*

POLYPODIOPSIDA

ASPLENIACEAE

Asplenium platyneuron (L.) Oakes.ex D.C. Eat., oak hickory ridge, occasional, *JMJ 1308.*

BLECHNACEAE

Woodwardia areolata (L.) Moore, forest swales, occasional, *DJR 1384.*

Woodwardia virginica (L.) Sm., mixed woods, occasional, *DJR 1059.*

DENNSTAEDTIACEAE

Pteridium aquilinum (L.) Kuhn, oak hickory ridge, occasional, *DJR 1397.*

DRYOPTERIDACEAE

Onoclea sensibilis L., forest swales, infrequent, *DJR 1388.*

OSMUNDACEAE

Osmunda regalis L, forest swales, occasional, *DJR 1066.*

PARKERIACEAE

**Ceratopteris thalichtroides* (L.) Brongn., gum swamps, very rare, *DJR 1746.*

POLYPODIACEAE

Pleopeltis polypodioides (L.) Andrews & Windham var. *michauxiana* (Weath.) Andrews & Windham, epiphyte on live oaks, frequent, *JMJ 1343.*

LYGODIACEAE

**Lygodium japonicum* (Thunb.) Sw., mixed woods, beech magnolia woods, occasional, *JMJ 1328.*

THELYPTERIDACEAE

Thelypteris kunthii (Desv.) Morton., roadsides, mixed woods, frequent, *DJR 1060.*

PINOPSIDA

PINACEAE

Pinus elliottii Engelm. var. *elliottii*, pine flatwoods, mixed woods, abundant, *DJR 1953.*

Pinus taeda L., pine flatwoods, mixed woods, longleaf pine savanna, abundant, *DJR 984.*

Pinus glabra Walt, beech magnolia woods, ridges, occasional, *DJR 1221.*

Pinus palustris Mill., longleaf pine savanna, frequent, *DJR 1682.*

TAXODIACEAE

Taxodium ascendens Brongn., fresh marsh, infrequent, *JMJ 1303.*

Taxodium distichum L., bayou edge, fresh marsh, occasional, *JMJ 1291.*

LILIOPSIDA

ALISMATACEAE

Echinodorus cordifolius (L.) Griseb., floodplain swamps, frequent, *DJR 1740.*

Sagittaria graminea Michx., borrow ditches, forest swales, frequent, *JMJ 1315.*

Sagittaria lancifolia L., fresh marsh, borrow ditches, abundant, *DJR 1356.*

ALLIACEAE

Allium canadense L., disturbed places, frequent, *DJR 1038.*

AMARYLLIDACEAE

Crinum americanum L., canal W of Lake Road, occasional, *DJR 1241.*

Hymenocallis lirosome (Raf.) Shinners, forest swales, occasional, *DJR 999.*

ARACEAE

Arisaema triphylla (L.) Schott. subsp. *quinatum* (Nutt.) Hutt., oak hickory ridge, infrequent, *JMJ 1273.*

**Colocasia esculenta* (L.) Schott, borrow ditches, rare, *DJR 1225.*

Peltandra virginica (L.) Schott, bayou edge, infrequent, *DJR 1051.*

ARECACEAE

Sabal minor (Jacq.) Pers., mixed woods, forest swales, gum swamps, frequent, *JMJ 1314.*

BROMELIACEAE

Tillandsia usneoides L., mixed woods, frequent, *JMJ 1290.*

COMMELINACEAE

Commelina diffusa Burm., forest swales, frequent, *DJR 1020.*

Commelina virginica L., forest swales, occasiona , *DJR 1265.*

Tradescantia hirsutiflora Bush, roadsides, mixed woods, occasional, *DJR 1392.*

Tradescantia virginiana L., oak hickory ridge, occasional, *JMJ 1272.*

CYPERACEAE

Bolboschoenus robustus (Pursh) Soják [*Scirpus robustus* Pursh], intermediate marsh, frequent, *DJR 1230.*

Carex abscondita Mack., beech magnolia woods, occasional, *DJR 1366.*

Carex albicans Willd. ex Spreng. var. *australis* (Bailey) J. Rettig, oak hickory ridge, frequent, *DJR 968.*

Carex albolutescens Schwein., beech magnolia woods, infrequent, *DJR 1374.*

Carex complanata Torr. & Hook., oak hickory ridge, mixed woods, frequent, *DJR 1027.*

Carex crebriflora Wieg., floodplain swamps, infrequent, *DJR 1990.*

Carex debilis Michx. var. *debilis*, floodplain swamps, infrequent, *DJR 1437.*

Carex digitalis Schkuhr ex Willd. var. *floridana* (Bailey) R. Naczi & C. Bryson, beech magnolia woods, occasional, *DJR 1370.*

Carex flaccosperma Dew., oak hickory ridge, frequent, *DJR 1025.*

Carex frankii Kunth, forest swales, infrequent, *DJR 1110.*

Carex gigantea Rudge, gum swamps, rare, *DJR 1103.*

Carex glaucescens Ell., pine flatwoods, occasional, *DJR 950.*

Carex joorii L. H. Bailey, gum swamps, occasional, *DJR 1744.*

Carex lonchocarpa Willd., floodplain swamps, in frequent, *DJR 1436.*

Carex longii Mack., oak hickory ridge, mixed woods, frequent, *DJR 1028.*

Carex louisianica L. H. Bailey, forest swales, flood plain swamps, infrequent, *DJR 1432.*

Carx lurida Wahl., borrow ditcnes, infrequent *DJR 2003.*

Carex nigromarginata Schwein. var. *floridana* (Schwein.) Kükenth, beech magnolia woods, occasional, *DJR 1974.*

Carex reniformis (L. H. Bailey) Small, floodplain swamps, occasional, *DJR 1435.*

Carex striatula Michx., beech magnolia woods, occasional, *DJR 1369.*

Carex texensis (Torr.) L.H. Bailey, disturbed places, infrequent, *DJR 1041.*

Carex triangularis Bock., beech magnolia woods, occasional, *DJR 1365.*

Carex tribuloides Wahl. var. *sangamonensis* Clokey, beech magnolia woods, floodplain swamps, occasional, *DJR 1368.*

Cladium mariscus (L.) Pohl subsp. *jamaicense* (Crantz) Kükenth., fresh marsh, pine flatwoods, frequent, *DJR 1207.*

Cyperus croceus Vahl., disturbed places, frequent, *DJR 1200.*

Cyperus haspan L., forest swales, frequent, *JMJ 1243.*

Cyperus odoratus L. var. *odoratus*, Intermediate marsh, occasional, *DJR 1672.*

Cyperus polystachyos Rottb., fresh marsh, occasional, *DJR 1259.*

Cyperus pseudovegetus Steud. var. *pseudovegetus*, disturbed places, frequent, *DJR 1085.*

Cyperus retrorsus Chapm., disturbed places, frequent, *DJR 952.*

Cyperus thyrsiflorus Jung., disturbed places, frequent, *DJR 1084.*

Cyperus virens Michx. var. *virens*, disturbed places, Forest swales, frequent, *DJR 1083.*

Eleocharis cellulosa Torr., intermediate marsh, pine flatwoods, frequent, *DJR 896.*

Eleocharis microcarpa Torr. var. *microcarpa*, pine flatwoods, frequent, *DJR 901.*

Eleocharis montevidensis Kunth, palustrine areas, frequent, *DJR 1000.*

Eleocharis obtusa (Willd.) Schult., forest swales, infrequent, *DJR 1026.*

Eleocharis olivacea Torr, fresh marsh mud flats, infrequent, *DJR 1260.*

Eleocharis palustris (L.) R. & S., fresh marsh, abundant, *DJR 1984.*

Eleocharis parvula (R. & S.) Link var. *anachaeta* (Torr.) Svens., fresh and intermediate marsh mud flats, frequent, *DJR 843.*

Eleocharis quadrangulata (Michx.) R. & S., borrow ditches, rare, *DJR 1094.*

Eleocharis tuberculosa (Michx.) R. & S., pine flatwoods, frequent, *DJR 897.*

Fimbristylis caroliniana (Lam.) Fern., pine flatwoods, frequent, *DJR 1249*.

Fimbristylis castanea (Michx.) Vahl., intermediate marsh, frequent, *DJR 922*.

Fimbristylis dichotoma (L.) Vahl., disturbed places, occasional, *DJR 1219*.

**Fimbristylis miliacea* (L.) M. H. Vahl, disturbed places, occasional, *DJR 1706*.

Furiena breviseta (Cov.) Cov., pine flatwoods, occasional, *DJR 898*.

Isolepis carinata Hook. & Arn. ex Torr. [*Scirpus koilolepis* (Steud.) Gl.], wet, sandy forest roads, frequent, *DJR 1349*.

Kylingia brevifolia Rottb., disturbed places, infrequent, *DJR 1049*.

Rhynchospora caduca Ell., mixed woods, frequent, *DJR 1073*.

Rhynchospora cephalantha A. Gray, wet clearcuts, frequent, *DJR 1234*.

Rhynchospora colorata (L.) H. Pfeiffer [*Dichromena colorata* (L.) Hitchc.], pine flatwoods, occasional, *DJR 912*.

Rhynchospora corniculata (Lam.) A. Gray, pine flatwoods, forest swales, frequent, *JMJ 1321*.

Rhynchospora debilis Gale, bogs, frequent, *DJR 1655*.

Rhynchospora elliottii D. Dietr., wet clearcuts, frequent, *DJR 1233*.

Rhynchospora fascicularis (Michx.) Vahl, pine flatwoods, frequent, *DJR 888*.

Rhynchospora gracilenta A. Gray, wet clearcuts, frequent, *DJR 1235*.

Rhynchospora inexpansa (Michx.) Vahl, pine flatwoods, frequent, *DJR 890*.

Rhynchospora perplexa Britt., wet clearcuts, frequent, *DJR 1116*.

Rhynchospora rariflora (Michx.) Ell., wet clearcuts, occasional, *DJR 1120*.

Schoenoplectus americanus (Pers.) Volk. [*Scirpus americanus* Pers.], fresh marsh, frequent, *DJR 1082*.

Schoenoplectus tabernaemontani (K. C. Gmel.) Palla [*Scirpus validus* Vahl], fresh marsh, frequent, *DJR 1081*.

Scleria oligantha Michx., oak hickory ridge, infrequent, *DJR 1029*.

Scleria pauciflora Muhl. ex Willd. var. *pauciflora*, pine savanna, occasional, DJR 1955.

Scleria triglomerata Michx., wet clearcuts, frequent, *DJR 951*.

Scleria verticillata Muhl. ex Willd., longleaf pine savanna, infrequent, *DJR 1697*.

ERIOCAULACEAE

Eriocaulon decangulare L., bogs, occasional, *JMJ 1320*.

HYDROCHARITACEAE

Vallisneria americana Michx., bayous, roadside canals, occasional, *DJR 2005*.

HYPOXIDACEAE

Hypoxis curtissii Rose, floodplain swamps, infrequent, *DJR 1997*.

Hypoxis hirsuta (L.) Cov., roadsides, infrequent, *DJR 990*.

IRIDACEAE

Iris hexagona Walt., borrow ditches, frequent, *DJR 1015*.

Iris virginica L., gum swamps, forest swales, bayou edges, frequent, *JMJ 1297*.

Sisyrinchium atlanticum Bickn., roadsides, frequent, *DJR 1009*.

**Sisyrinchium exile* Bickn., disturbed places, frequent, *DJR 1012*.

JUNCACEAE

Juncus brachycarpus Engelm., pine flatwoods, occasional, *DJR 2007*.

Juncus bufonius L., spoil levees, occasional, *DJR 1408*.

Juncus coriaceus Mack., forest swales, occasional, *DJR 1732*.

Juncus diffusissimus Buckl., borrow ditches, occasional, *DJR 1088*.

Juncus effusus L., borrow ditches, frequent, *DJR 1016*.

Juncus elliottii Chapm., wet clearcuts, frequent, *DJR 1010*.

Juncus marginatus Rostk., disturbed places, occasional, *DJR 1047*.

Juncus polycephalus Michx., borrow ditches, frequent, *DJR 1093*.

Juncus repens Michx., forest swales, occasional, *DJR 1197*.

Juncus roemerianus Scheele, intermediate marsh, abundant, *DJR 986*.

Juncus tenuis willd. var. *dichotomus* (Ell.) Wood, forest swales, occasional, DJR 1982.

Juncus tenuis Willd. var. *tenuis*, forest swales, frequent, *DJR 1994*.

LEMNACEAE

Lemna minor L., gum swamps, frequent, *DJR 1063.*

NAJADACEAE

Najas guadalupensis (Spreng.) Magnus, Cane Bayou canoe launch, frequent, *DJR 1203.*

ORCHIDACEAE

Spiranthes odorata (Nutt.) Lindl., gum swamps, infrequent, *DJR 1745.*

Spiranthes praecox (Walt.) S. Wats., beech magnolia woods, occasional, *JMJ 1312.*

POACEAE

Agrostis hyemalis (Walt.) B.S.P., roadsides, occasional, *DJR 1068.*

Andropogon glomeratus (Walt.) B.S.P. var. *glaucopsis* (Ell.) Mohr, longleaf pine savanna, frequent, *DJR 1664.*

Andropogon glomeratus (Walt.) B.S.P. var. *pumilus* Vasey, longleaf pine savanna, frequent, *DJR 1685*

Andropogon gyrans Ashe var. *stenophyllus* (Hack.) C. Campb., longleaf pine savanna, frequent, *DJR 1676.*

Andropogon virginicus L. var. *virginicus*, mixed woods, clearcuts, abundant, *DJR 1684.*

Anthaenantia rufa (Ell.) Schult., bogs, infrequent, *DJR 948.*

Aristida longespica Poir. var. *geniculata* (Raf.) Fern., longleaf pine savanna, occasional, *DJR 893.*

Arundinaria gigantea (Walt.) Muhl. subsp. *gigantea*, mixed woods, occasional, *DJR 1423.*

Axonopus fissifolius (Raddi) Kuhlm., pine flatwoods, occasional, *DJR 899.*

**Briza minor* L., roadsides, frequent, *DJR 1014.*

**Bromus catharticus* Vahl, disturbed places, frequent, *DJR 1039.*

Chasmanthium laxum (L.) Yates var. *laxum*, mixed woods, beech magnolia woods, abundant, *DJR 1206.*

Chasmanthium laxum (L.) H. Yates var. *sessiliflorum* (Poir.) Wipff & S. D. Jones, mixed woods, infrequent, *DJR 1731.*

Ctenium aromaticum (Walt.) Wood, bogs, infrequent, *DJR 947.*

**Cynodon dactylon* (L.) Pers., disturbed places, frequent, *DJR 1031.*

Digitaria ciliaris (Retz.) Koel, roadsides, frequent, *DJR 1220.*

Distichlis spicata (L.) Greene, intermediate marsh, frequent, *JMJ 1334.*

**Echinochloa crus-galli* (L.) Beauv. var. *crus-galli*, fresh marsh, occasional *DJR 1268.*

Elymus virginicus L. var. *virginicus*, roadsides, occasional, *DJR 1108.*

Eragrostis elliottii S. Wats., pine flatwoods, occasional, *DJR 895.*

Eragrostis hypnoides (Lam.) B.S.P., gum swamps, frequent, *DJR 1271.*

Eragrostis spectabilis (F. Pursh) E. von Steudel, longleaf pine savanna, infrequent, *DJR 1666.*

**Eremochloa ophiuroides* (Munro) Hack., disturbed places, frequent, *JMJ 1340.*

Hordeum pusilum Nutt., roadsides, frequent, *DJR 1001.*

Imperata brasiliensis* (L.) Beauv., roadsides, occasional, *DJR 1034.* **Federal noxious weed

Leersia hexandra Sw., borrow ditches, occasional, *JMJ 1332.*

Leersia lenticularis Michx., forest swales, occasional, *DJR 1718.*

Leersia oryzoides (L.) Sw., borrow ditches, infrequent, *DJR 1741.*

Leersia virginica Willd., mixed woods, occasional, *DJR 1742.*

Leptochloa fusca (L.) Kunth subsp. *fascicularis* (Lam.) N. Snow., intermediate and fresh marsh, frequent, *DJR 1673.*

**Lolium arundinaceum* (Schreb.) S. J. Darbyshire [*Festuca arundinacea* Schreb.], roadsides, occasional, *DJR 1087.*

**Lolium perenne* L., disturbed places, frequent, *DJR 1091.*

Melica mutica Walt., disturbed roadside, occasional, *DJR 1419.*

Muhlenbergia expansa (Poir.) Trin., pine savanna, infrequent, *DJR 946.*

Oplismenus hirtellus (L.) Beauv., oak hickory ridge, frequent, *DJR 931.*

Panicum aciculare Desv. *ex* J. Poiret var. *angustifolium* (Ell.) Wipff & S. D. Jones., mixed woods, frequent, *DJR 1414.*

Panicum acuminatum Sw. var. *acuminatum*, oak hickory ridge, infrequent, *DJR 1023.*

Panicum acuminatum SW. var. *fasciculatum* (Torr.) Lelong., mixed woods, frequent, *DJR 1345.*

Panicum anceps Michx., wet clearcuts, infrequent, *DJR 954.*

Panicum boscii J. Poiret, beech magnolia woods, frequent, *DJR 1976*.
Panicum commutatum Schult. var. *joorii* (Vasey) Fern., mixed woods, frequent, *DJR 1378*.
Panicum consanguineum Kunth, mixed woods, frequent, *DJR 1343*.
Panicum dichotomiflorum Michx. subsp. *dichotomiflorum*, disturbed sites, infrequent, *DJR 1659*.
Panicum dichotomum C. Linnaeus var. *lucidum* (Ashe) Lelong, beech magnolia woods, frequent, *DJR 1373*.
Panicum dichotomum L. var. *ramulosum* (Torr.) Lelong, oak hickory ridge, infrequent, *DJR 1396*.
Panicum dichotomum L. var. *roanokense* (Ashe) Lelong, mixed woods, frequent, *DJR 1346*.
Panicum gymnocarpon Ell., floodplain swamps, occasional, *DJR 1737*.
Panicum hians Ell., roadsides, occasional, *DJR 1069*.
Panicum laxiflorum Lam., oak hickory ridge, occasional, *DJR 1375*.
Panicum portoricense Desv. ex Hamilt. var. *nashianum* (Scribn.) Lelong, mixed woods, frequent, *DJR 1347*.
Panicum repens L., wet clearcuts, borrow ditches, abundant, *DJR 1236*.
Panicum rigidulum Nees. var. *rigidulum*, pine flatwoods, occasional, *DJR 1747*.
Panicum rigidulum Nees var. *pubescens* (Vasey) Lelong, longleaf pine savanna, infrequent, *DJR 1691*.
Panicum scoparium Lam., mixed Forests, frequent, *DJR 1193*.
Panicum sphaerocarpon Ell., disturbed sites, frequent, *DJR 1411*.
Panicum verrucosum Muhl., pine flatwoods, wet clearcuts, frequent, *DJR 905*.
Panicum virgatum L., intermediate marsh, pine flatwoods, frequent, *DJR 1239*.
**Parapholis incurva* (L.) C. Hubbard, spoil levees, frequent, *DJR 1416*.
Paspalum conjugatum Berg., disturbed places, frequent, *DJR 1269*.
**Paspalum dilatatum* Poir., disturbed places, frequent, *DJR 1114*.
Paspalum dissectum (L.) L., gum swamps, frequent, *DJR 1210*.
Paspalum floridanum Michx. var. *floridanum*, pine flatwoods, occasional, *DJR 891*.
Paspalum floridanum Michx. var. *glabratum* Engelm. ex Vasey, roadsides, frequent, *DJR 1237*.
Paspalum laeve Michx., pine flatwoods, occasional, *DJR 892*.
Paspalum lividum Trin., borrow ditches, frequent, *DJR 1248*.
**Paspalum notatum* Flüggé, disturbed places, occasional, *JMJ 1326*.
Paspalum plicatulum Michx. var. *plicatulum*, pine flatwoods, occasional, *DJR 1097*.
Paspalum praecox Walt., wet clearcuts, occasional, *DJR 949*.
Paspalum setaceum Michx., longleaf pine savanna, frequent, *DJR 1678*.
**Paspalum urvillei* Steud., disturbed places, occasional, *DJR 900*.
Paspalum vaginatum Sw., spoil levees, frequent, *DJR 1716*.
Phalaris angusta Nees ex Trin., disturbed roadsides, infrequent, *DJR 1402*.
Phalaris caroliniana Walt., disturbed areas, infrequent, *DJR 1412*.
Phragmites communis Trin., along canals, occasional, *DJR 1749*.
**Poa annua* L., roadsides, frequent, *DJR 981*.
**Polypogon monspeliensis* (L.) Desf., disturbed areas, frequent, *DJR 1090*.
Saccharum baldwinii Spreng. [*Erianthus strictus* Baldw.], mixed woods, frequent, *DJR 936*.
Saccharum giganteum (Walt.) Pers. [*Erianthus giganteus* (Walt.) Muhl.], mixed woods, frequent, *DJR 1656*.
Schizachyrium scoparium (Michx.) Nash. var. *scoparium*, pine flatwoods, mixed woods, frequent, *DJR 1662*.
Setaria parviflora (Poir.) Kerguélen, roadsides, frequent, *DJR 1112*.
**Sorghum halepense* (L.) Pers., disturbed places, occasional, *DJR 1205*.
Spartina alterniflora Lois., Intermediate marsh, occasional, *DJR 956*.
Spartina cynosuroides (L.) Roth, intermediate marsh, infrequent, *DJR 1231*.
Spartina patens (Ait.) Muhl., pine flatwoods, intermediate marsh, abundant, *DJR 923*.
Sphenopholus obtusata (Michx.) Scribn., roadsides, frequent, *DJR 979*.

Sporobolus indicus (L.) R. Br., roadsides, frequent, *DJR 1005*.

Sporobolus virginicus (L.) Kunth, spoil levees, frequent, *DJR 1713*.

**Stenotaphrum secundatum* (Walt.) O. Ktze., disturbed places, frequent, *JMJ 1341*.

Tridens ambiguus (Ell.) Schult., pine flatwoods, occasional, *DJR 902*.

Tridens flavus (L.) Hitchc. var. *flavus*, disturbed roadsides, infrequent, *DJR 1750*.

Tridens strictus (Nutt.) Nash, pine flatwoods, occasional, *DJR 903*.

Tripsacum dactyloides (L.) L. var. *dactyloides*, disturbed roadsides, infrequent, *DJR 1201*.

Vulpia octoflora (Walt.) Rydb. var. *octoflora*, disturbed areas, occasional, *DJR 1409*.

Zizaniopsis miliacea (Michx.) Doell & Asch., borrow ditches, fresh marsh, frequent, *DJR 1052*.

PONTEDERIACEAE

Pontederia cordata L., borrow ditches, frequent, *DJR 1070*.

POTAMOGETONACEAE

Potamogeton diversifolius Raf, small lake at Boy Scout Road, infrequent, *DJR 1428*.

RUPPIACEAE

Ruppia maritima L., Bayou Lacombe, marsh ponds, frequent, *JMJ 1292*.

SMILACACEAE

Smilax bona-nox L., mixed woods, infrequent, *DJR 1011*.

Smilax glauca Walt., mixed woods, occasional, *DJR 1352*.

Smilax laurifolia L., bogs, occasional, *DJR 1951*.

Smilax pumila Walt., mixed woods, occasional, *DJR 1385*.

Smilax rotundifolia L., floodplain swamps, mixed woods, frequent, *DJR 970*.

Smilax smallii Morong, mixed woods, frequent, *DJR 1351*.

Smilax tamnoides L., mixed woods, occasional, *DJR 1954*.

Smilax walteri Pursh, beech magnolia woods, occasional, *DJR 1363*.

TYPHACEAE

Typha latifolia L., fresh marsh, borrow ditches, frequent, *DJR 1222*.

XYRIDACEAE

Xyris ambigua Beyr. ex Kunth, pine savanna, occasional, *JMJ 1247*.

Xyris laxifolia Mart. var. *iridifolia* (Chapm.) Kral, pine savanna, occasional, *DJR 1710*.

Xyris stricta Chapm., pine savanna, frequent, *DJR 1198*.

ZANNICHELLIACEAE

Zannichellia palustris L., Bayou Lacombe, marsh ponds, frequent, *JMJ 1293*.

MAGNOLIOPSIDA

ACANTHACEAE

Ruellia humilis Nutt., disturbed places, occasional, *DJR 1053*.

ACERACEAE

Acer rubrum L. var. *drummondii* (Hook. & Arn. ex Nutt.) Sarg., floodplain swamps, forest swales, frequent, *JMJ 1259*.

Acer rubrum L. var. *rubrum*, beech magnolia woods, occasional, *DJR 1359*.

Acer rubrum L. var. *trilobum* Torr. & A. Gray ex K. Koch., forest swales, occasional, *DJR* sight record.

AMARANTHACEAE

**Alternanthera philoxeroides* (Mart.) Griseb., borrow ditches, fresh marsh, frequent, *DJR 915*.

**Amaranthus* cf. *cannabinus* (L.) Sauer, fresh marsh, abundant, *DJR 1264*.

ANACARDIACEAE

Rhus copallinum L., mixed woods, frequent, *DJR 1255*.

Toxicodendron radicans (L.) Kuntze, throughout, abundant, *DJR 2006*.

APIACEAE

**Centella erecta* (L. f.) Fern., pine flatwoods, wet clearcuts, frequent, *JMJ 1220*.

Chaerophyllum tainturieri Hook., disturbed roadsides, occasional, *DJR 1381*.

**Cyclospermum leptophyllum* (Pers.) Sprag. ex Britt. & P. Wils., roadsides, frequent, *DJR 980*.

Eryngium yuccifolium Michx., pine flatwoods, frequent, *DJR 1199*.

Hydrocotyle verticillata Thunb., palustrine areas, frequent, *DJR 1042*.

Oxypolis filiformis (Walt.) Britt., pine flatwoods, occasional, *DJR 1258*.

Ptilimnium capillaceum (Michx.) Raf., floodplain swamps, fresh marsh, frequent, *DJR 2000.*
Sanicula canadensis L., mixed woods, frequent, *DJR 1046.*

APOCYNACEAE

Trachelospermum difforme (Walt.) A.Gray., mixed woods, frequent, *DJR 1337.*

AQUIFOLIACEAE

Ilex cassine L., wet woods, very rare, *DJR 909.*
Ilex decidua T. Walter, wet woods, rare, *DJR 1987.*
Ilex glabra (L.) A. Gray, mixed woods, occasional, *DJR 1348.*
Ilex myrtifolia Walt., mixed woods, frequent, *DJR 1652.*
Ilex opaca Ait., mixed woods, occasional, *DJR 994.*
Ilex verticillata (L.) A. Gray, floodplain swamps, infrequent, *DJR 1989.*
Ilex vomitoria Ait., mixed woods, frequent, *DJR 993.*

ARALIACEAE

Aralia spinosa L., oak hickory ridge, frequent, *JMJ 1344.*

ARISTOLOCHIACEAE

Aristolochia serpentaria L., beech magnolia woods, infrequent, *DJR 1978.*

ASCLEPIADACEAE

Asclepias lanceolata Walt., pine flatwoods, frequent, *JMJ 1304.*
Asclepias longifolia Michx., bogs, infrequent, *DJR 1957.*
Cynanchum angustifolium Pers., pine flatwoods, intermediate marsh, frequent, *DJR 1109.*
Matelea gonocarpos (Walt.) Shinners, beech magnolia woods, infrequent, *JMJ 1301.*

ASTERACEAE

Acmella oppositifolia (Lam.) R. Jansen var. *repens* (Walt.) R. Jansen, disturbed roadsides, occasional, *DJR 1738.*
Ambrosia artemisifolia L., disturbed roadsides, frequent, *JMJ 1345.*
Baccharis angustifolia Michx, pine flatwoods, occasional, *DJR 928.*
Baccharis halimifolia L., disturbed roadsides, pine flatwoods, frequent, *DJR 925.*
Baldunia uniflora Nutt., bogs, infrequent, *DJR 944.*
Bidens aristosa (Michx.) N. Britton, forest swales, occasional, *DJR 1708.*
Bidens mitis (Michx.) Sherff, wet clearcuts, infrequent, *DJR 942.*
Bigelowia nudata (Michx.) DC., pine flatwoods, frequent, *DJR 906.*
Boltonia asteroides (L.) L'Her., pine flatwoods, occasional, *DJR 926.*
Boltonia diffusa Ell., pine flatwoods, occasional, *DJR 1668.*
Carphephorus odoratissimus (J. F. Gmel.) Cass., wet clearcuts, infrequent, *JMJ 1242.*
Carphephorus pseudoliatris Cass., wet clearcuts, occasional, *DJR 945.*
Cirsium horridulum Michx., roadsides, abundant, *JMJ 1262.*
Conoclinum coelestinum (L.) DC. [*Eupatorium coelestinum* L.], roadsides, frequent, *DJR 927.*
**Conyza bonariensis* (L.) Cronq., disturbed roadsides, occasional, *DJR 1277.*
Conyza canadensis (L.) Cronq., spoil levees, infrequent, *DJR 1715.*
Eclipta prostrata (L.) L., borrow ditches, frequent, *DJR 916.*
Elephantopus carolinianus Raeusch., mixed woods, frequent, *DJR 1687.*
Elephantopus elatus Bert., mixed woods, occasional, *DJR 1696.*
Elephantopus nudatus A. Gray, mixed woods, occasional, *DJR 1688.*
Erigeron philadelphicus L., roadsides, occasional, *JMJ 1257.*
Erigeron vernus (L.) Torr. & A. Gray, pine savanna, occasional, *DJR 1956.*
Eupatorium capillifolium (Lam.) Small, disturbed roadsides, waste places, frequent, *JMJ 1227.*
Eupatorium leucolepis (DC.) Torr. & A. Gray, pine savanna, occasional, *JMJ 1225.*
Eupatorium perfoliatum L., mixed woods, occasional, *DJR s.n.*
Eupatorium rotundifolium L., pine flatwoods, occasional, *DJR 1273.*
Eupatorium serotinum Michx., mixed woods, occasional, *DJR* sight record.
Euthamia gymnospermoides Greene, mixed woods, occasional, *DJR 1675.*
Euthamia leptocephala (Torr. & A. Gray) Greene, pine flatwoods, frequent, *DJR 934.*
Gamochaeta purpurea (L.) Cabrera [*Gnaphalium purpureum* L.], waste places, frequent, *DJR 1040.*

Helenium amarum (Raf.) Rock, disturbed road sides, frequent, *JMJ 1226.*

Helenium flexuosum Raf., roadsides, pine flatwoods, frequent, *DJR 1067.*

Helianthus angustifolius L., pine savanna, frequent, *DJR 941.*

Helianthus heterophyllus Nutt., pine savanna, occasional, *DJR 943.*

*Hypochaeris microcephala (Sch. Bip.) Cabrera var. albiflora (O. Ktze.) Cabrera, roadsides, occasional, DJR 2002.

Iva annua L., disturbed roadsides, frequent, *DJR 1262.*

Iva frutescens L., intermediate marsh, roadsides, abundant, *DJR 1242.*

Krigia caespitosa (Raf.) Chambers, roadsides, frequent, *DJR 1003.*

Mikania scandens (L.) Willd., pine flatwoods, occasional, *JMJ 1231.*

Packera glabella (J. Poiret) C. Jeffrey [*Senecio glabellus* J. Poiret], disturbed areas, infrequent, *DJR 1406.*

Pityopsis graminifolia (Michx.) Nutt., hummocks on marsh edge, occasional, *DJR 1698.*

Pluchea rosea Godfrey, roadsides, frequent, *DJR 1245.*

Pyrrhopappus pauciflorus (D. Don) DC., roadsides, occasional, *DJR 1078.*

Solidago arguta Ait., pine flatwoods, occasional, *JMJ 1223*

Solidago canadensis L. var. *scabra* (Muhl. ex Willd.) Torr. & A. Gray, disturbed places, occasional, *DJR 1722.*

Solidago rugosa Mill., oak hickory ridge, frequent, *JMJ 1237.*

Solidago sempervirens L., intermediate marsh, pine flatwoods, occasional, *JMJ 1305.*

**Soliva sessilis* R. & P., disturbed places, frequent, *DJR 1963.*

**Sonchus asper* (L.) Hill, rodsides, frequent, *DJR 976.*

Stokesia laevis (Hill) Greene, pine savanna, infrequent, *JMJ 1249.*

Symphyotrichum divaricatum (Nutt.) Nesom [*Aster divaricatus* (Nutt.) Torr. & A. Gray], mixed woods, frequent, *DJR 1669.*

Symphyotrichum dumosum (L.) Nesom [*Aster dumosus* L.], pine flatwoods, occasional, *DJR 933.*

Symphyotrichum lateriflorum (L.) Löve & Löve [*Aster lateriflorus* (L.) Britt.], mixed woods, occasional, *DJR s.n.*

Symphyotrichum patens (Ait.) Nesom [*Aster patens* Ait.], mixed woods, frequent, *DJR 1699.*

Symphyotrichum praealtum (Poir.) Nesom [*Aster praealtus* Poir.], mixed woods, frequent, *DJR 1667.*

Symphyotrichum subulatum (Michx.) Nesom [*Aster subulatus* Michx.], pine flatwoods, frequent, *DJR 924.*

Symphyotrichum tenuifolium (L.) Nesom [*Aster tenuifolius* L.], intermediate Marsh, frequent, *DJR 957.*

**Taraxacum officinale* G.H. Weber ex Wiggers, roadsides, common, *JMJ 1255.*

Verbesina virginica L., roadsides, frequent, *DJR* sight record.

Xanthium strumarium L., roadsides, infrequent, *DJR 1711.*

**Youngia japonica* (L.) DC., roadsides, frequent, *DJR 973.*

BETULACEAE

Carpinus caroliniana Walt., mixed woods, beech magnolia woods, frequent, *DJR 1079.*

BIGNONIACEAE

Bignonia capreolata L., mixed woods, frequent, *DJR 997.*

Campsis radicans (L.) Seem. ex Bur., mixed woods, frequent, *JMJ 1325.*

BORAGINACEAE

**Heliotropium indicum* L., gum swamps, frequent, *DJR 1209.*

Myosotis macrosperma Engelm., mixed woods, frequent, *DJR 1050.*

BRASSICACEAE

Lepidium virginicum L., disturbed places, occasional, *DJR 1048.*

Rorippa palustris (L.) Bess. subsp. *fernaldiana* (Butt. & E. Abbe) B.E. Jonsell, roadsides, occasional, DJR 2001.

BUDDLEJACEAE

Polypremum procumbens L., pine flatwoods, roadsides, occasional, *DJR 1251.*

CALLITRICHACEAE

Callitriche heterophylla Pursh., borrow ditches, occasional, *DJR 1389.*

CAMPANULACEAE

Lobelia brevifloia Nutt. ex A. DC., longleaf pine savanna, occasional, *DJR 1681.*

Lobelia puberula Michx., oak hickory ridge, pine flatwoods, occasional, *JMJ 1234.*

Lobelia spicata Lam., beech magnolia woods, occasional, *DJR 1730.*

Triodanus perfoliata (L.) Nieuw., roadsides, frequent, *DJR 1043.*

CAPRIFOLIACEAE

**Lonicera japonica* Thunb., oak hickory ridge, occasional, *JMJ 1276.*

Sambucus canadensis L., disturbed roadsides, occasional, *DJR 1105.*

Viburnum dentatum L., oak hickory ridge, mixed woods, frequent, *DJR 1107.*

CARYOPHYLLACEAE

**Cerastium glomeratum* Thuill., disturbed roadsides, occasional, *JMJ 1285.*

Spergularia marina (L.) Griseb., spoil levees, frequent, *DJR 1410.*

CERATOPHYLLACEAE

Ceratophyllum demersum L., Cane Bayou canoe launch, frequent, *DJR 1202.*

CISTACEAE

Lechea tenuifolia Michx., frquent, marsh edge, *DJR 1671.*

CLUSIACEAE

Hypericum brachyphyllum (Spach) Steud, pine flatwoods, frequent, *DJR 1247.*

Hypericum cistifolium Lam., pine flatwoods, occasional, *JMJ 1221.*

Hypericum denticulatum Walt., pine flatwoods, occasional, *DJR 1250.*

Hypericum gymnanthum Engelm. & A. Gray, forest swale, occasional, *DJR 1194.*

Hypericum hypericoides (L.) Crantz, oak hickory ridge, frequent, *JMJ 1238.*

CONVOLVULACEAE

Calystegia sepium (L.) R.Br., roadsides, occasional, *JMJ 1313.*

Dichondra carolinensis Michx., waste places, frequent, *DJR 1044.*

Ipomoea sagitata Poir., intermediate marsh, frequent, *DJR 1229.*

CORNACEAE

Cornus foemina Mill, floodplain swamps, frequent, *DJR 1438.*

CUCURBITACEAE

Melothria pendula L., disturbed Forest, occasional, *DJR 1422.*

CUSCUTACEAE

Cuscuta indecora Choisy, intermediate marsh, abundant, *JMJ 1335.*

DROSERACEAE

Drosera capillaris Poir. var. *capillaries*, bogs, frequent, *DJR 1959.*

EBENACEAE

Diospyros vriginiana L., mixed woods, frequent, *DJR 1035.*

ERICACEAE

Rhododendron viscosum (L.) Torr., floodplain swamps, infrequent, *DJR 1988.*

Vaccinium arboreum Marsh., oak hickory ridge, occasional, *JMJ 1266.*

Vaccinium corymbosum L., mixed woods, occasional, *DJR 1341.*

Vaccinium stamineum L., mixed woods, occasional, *DJR 1338.*

EUPHORBIACEAE

Croton capitatus Michx. var. *lindheimeri* (Engelm. & A. Gray) J. Muell.-Arg., roadsides, frequent, *DJR 1274.*

Euphorbia humistrata Engelm., roadsides, disturbed places, frequent, *DJR 1243.*

Euphorbia maculata L., roadsides, disturbed places, frequent, *DJR 917.*

Euphorbia prostrata Ait., roadsides, disturbed places, frequent, *JMJ 1229.*

Phyllanthus caroliniensis Walt., gum swamps, frequent, *DJR 1211.*

**Phyllanthus urinaria* L., roadsides, disturbed places, occasional, *DJR 1218.*

**Sapium sebiferum* (L.) Roxb., mixed woods, gum swamps, pine flatwoods, occasional, *DJR 1106.*

FABACEAE

**Albizia julibrissin* I. Durazz., roadsides, infrequent, *DJR 1213.*

Amorpha fruticosa L., floodplains, occasional, *DJR 1075.*

Baptisia alba (L.) Vent. var. *macrophylla* (Larisey) Isely [*Baptisia lactea* (Raf.) Thieret], mixed woods, occasional, *DJR 1076*.

Centrosema virginiatum (L.) Benth., roadsides, frequent, *DJR 1253*.

Chamaecrista fasciculata (Michx.) E. Greene, mixed woods, frequent, *DJR 1689*.

Desmanthus illinoensis (Michx.) MacM., roadsides, frequent, *DJR 1232*.

Desmodium paucíflorum (Nutt.) DC., mixed woods, oak hickory ridge, frequent, *DJR 1058*.

Desmodium sessilifolium Torr. & A. Gray, mixed woods, frequent, *DJR 1694*.

Erythrina herbacea L., mixed woods, oak hickory ridge, frequent, *JMJ 1300*.

Gleditsia triacanthos L., floodplains, frequent, *DJR 1037*.

Lespedeza capitata Michx., mixed woods, frequent, *DJR 1695*.

**Medicago arabica* (L.) Huds., roadsides, frequent, *JMJ 1261*.

**Medicago lupulina* L., roadsides, occasional, *DJR 1981*.

**Melilotus indicus* (L.) All., roadsides, infrequent, *JMJ 1263*.

Neptunia lutea (Leavenw.) Benth., roadsides, frequent, *DJR 1228*.

Sesbania drummondii (Rydb.) Cory, Intermediate marsh, frequent, *DJR 1227*.

**Sesbania punicea* (Cav.) Benth. Floodplains, occasional, *JMJ 1283*.

Tephrosia spicata (Walt.) Torr. & A. Gray, mixed woods, occasional, *DJR 1702*.

**Trifolium campestre* Schreb.var. *campestre*, disturbed places, occasional, *DJR 1983*.

**Trifolium dubium* Sibth, disturbed places, frequent, *DJR 1045*.

**Trifolium repens* L., disturbed places, frequent, *JMJ 1280*.

**Vicia sativa* L., disturbed areas, frequent, *DJR 1413*.

**Vicia tetrasperma* (L.) Schreb., disturbed roadsides, occasional, *JMJ 1282*.

**Vicia villosa* Roth, disturbed roadsides, common, *DJR 1404*.

Vigna luteola (Jacq.) Benth, intermediate marsh, occasional, *JMJ 1299*.

Wisteria frutescens (L.) Poir, mixed woods, occasional, *DJR 1353*.

FAGACEAE

Fagus grandifolia Ehrh., beech magnolia woods, frequent, *DJR 1266*.

Quercus alba L., mixed woods, infrequent, *DJR 1434*.

Quercus falcata Michx. var. *falcata*, mixed woods, beech magnolia woods, frequent, *JMJ 1331*.

Quercus falcata Michx. var. *pagodifolia* Ell., mixed woods, frequent, *DJR 1095*.

Quercus laurifolia Michx., mixed woods, forest swales, frequent, *DJR 995*.

Quercus marilandica Muenchh., hummocks on marsh edge, rare, *DJR 1700*.

Quercus michauxii Nutt., oak hickory ridge, mixed woods, frequent, *DJR 930*.

Quercus nigra L., mixed woods, forest swales, occasional, *DJR 988*.

Quercus phellos L., forest swales, occasional, *DJR 991*.

Quercus similis Ashe, oak hickory ridge, mixed woods, occasional, *DJR 1342*.

Quercus sinuata Walt. var. *sinuata*, forested swales, rare, *DJR 1113*.

Quercus virginiana Mill., mixed woods, occasional, *DJR 989*.

GENTIANACEAE

Centaurium pulchellum (Sw.) Druce, waste places, infrequent, *JMJ 1307*.

Eustoma exaltatum (L.) Salib. ex G. Don., roadsides, occasional, *JMJ 1338*.

Sabatia calycina (Lam.) Heller, roadsides, occasional, *DJR 1071*.

Sabatia dodecandra (L.) B.S.P., roadsides, infrequent, *JMJ 1339*.

GERANIACEAE

Geranium carolinianum L., roadsides, frequent, *DJR 1006*.

GROSSULARIACEAE

Itea virginica L., floodplain swamps, occasional, *DJR 1995*.

HALORAGACEAE

**Myriophyllum* cf. *aquaticum* (Vell.) Verdc., gum swamps, infrequent, *DJR 1430*.

Myriophyllum pinnatum (Walt.) B.S.P., forest swales, frequent, *DJR 985*.

**Myriophyllum sibiricum* Kom., canals, marsh ponds, abundant, *DJR 1748*.

Proserpinaca pectinata Lam., pine savanna, occasional, *DJR 1117*.

HAMAMELIDACEAE

Hamamelis virginiana L., oak hickory ridge, rare, *JMJ 1265*.

Liquidambar styraciflua L., mixed woods, frequent, *DJR 987*.

HIPPOCASTANACEAE

Aesculus pavia L., beech magnolia woods, occasional, *DJR 1357*.

HYDROPHYLLACEAE

Hydrolea ovata Nutt. ex Choisy, palustirne, frequent, *DJR 1254*

JUGLANDACEAE

Carya glabra (Mill.) Sweet, mixed woods, oak hickory ridge, frequent, *DJR 1280*.

Carya illinoiensis (F. von Wangenheim) K. Koch, abandoned homesite, very rare, *JMJ 1281*.

LAMIACEAE

Hyptis alata (Raf.) Shinners, mixed woods, occasional, *DJR* sight record.

Lycopus rubellus C. Moench, forest swales, occasional, *DJR 1709*.

**Micromeria brownei* (Sw.) G. Bentham, roadsides, infrequent, *JMJ 1286*.

**Perilla frutescens* (L.) Britt., mixed woods margins, occasional, *DJR 1064*.

Salvia lyrata L., roadsides, frequent, *JMJ 1258*.

Scutellaria integrifolia L., mixed woods, frequent, *DJR 1056*.

Scutellaria ovata Hill, mixed woods, frequent, *DJR 1096*.

Stachys crenata Raf., roadsides, frequent, *JMJ 1287*.

Stachys floridana Shuttlw. ex Benth., disturbed areas, infrequent, *DJR 1426*.

Teucrium canadense L., mixed woods, infrequent, *JMJ 1346*.

Trichostema dichotomum L., pine savanna, occasional, *DJR 1690*.

LAURACEAE

Persea palustris (C. Rafinesque-Schmaltz Raf.) Sarg., mixed woods, infrequent, *DJR 1405*.

LENTIBULARIACEAE

Utricularia foliosa L., borrow ponds and ditches, occasional, *DJR 1724*.

Utricularia gibba L., borrow ponds and ditches, occasional, *DJR 1665*.

Utricularia purpurea Walt., pine flatwood ponds, borrow ditches, rare, *DJR 850*.

Utricularia radiata Small, borrow ponds and ditches, occasional, *DJR 977*.

Utricularia subulata L., bogs, frequent, *DJR 1960*.

LINACEAE

Linum medium (Planch.) Britt., pine flatwoods, frequent, *JMJ 1310*.

LOGANIACEAE

Gelsemium sempervirens St.-Hil., oak hickory ridge, frequent, *DJR 966*.

Mitreola petiolata (Walt.) Torr. & A. Gray, roadsides, frequent, *DJR 1275*.

LYTHRACEAE

Cuphea carthagenensis (Jacq.) Macbr., roadsides, frequent, *DJR 913*.

Lythrum lineare L., intermediate marsh, frequent, *DJR 1240*.

MAGNOLIACEAE

Magnolia grandiflora L., beech magnolia woods, frequent, *DJR 1204*.

Magnolia virginiana L., pine savanna, occasional, *JMJ 1319*.

MALVACEAE

Hibiscus aculeatus Walt., mixed woods, occasional, *DJR 1256*.

Hibiscus moscheutos L. subsp. *lasiocarpos* (A. Cavanilles) O. Blanchard, fresh marsh, floodplains, frequent, *DJR 1214*.

Kosteletzkya virginica (L.) K. Presl ex A. Gray, intermediate marsh, occasional *JMJ 1228*.

Modiola caroliniana (L.) G. Don, roadsides, occasional, *DJR 1065*.

Sida rhombifolia L., oak hickory ridge, waste places, abundant, *JMJ 1236*.

MELASTOMATACEAE

Rhexia mariana L., pine savanna margins, frequent, *JMJ 1317*.

MORACEAE

Morus rubra L., floodplains, occasional *DJR 1036*.

MYRICACEAE

Morella caroliniensis (Mill.) Small [*Myrica heterophylla* Raf.], mixed woods, occasional, *DJR 1350*.

Morella cerifera (L.) Small [*Myrica cerifera* (L.) Small], mixed woods, pine flatwoods, frequent, *DJR 974*.

NYMPHACEAE

Nuphar advena (Ait.) Ait. [*N. lutea* (L.) J. E. Sm.], borrow ditches, frequent, *DJR 1263.*

Nymphea odorata Ait. var. *odorata*, borrow ponds and ditches, marsh ponds and sloughs, abundant, *DJR 907.*

NYSSACEAE

Nyssa aquatica L., floodplain swamps, frequent, *DJR 1979.*

Nyssa biflora Walt., tupelo gum swamps, Frequent, *JMJ 1311.*

Nyssa sylvatica Marsh., mixed woods, frequent, *DJR 992.*

OLEACEAE

Fraxinus caroliniana Mill., floodplain swamps, occasional, *DJR 1080.*

**Ligustrum sinense* Lour., oak hickory ridge, mixed woods, frequent, *JMJ 1274.*

ONAGRACEAE

Gaura parviflora Dougl. ex Lehm., roadsides, infrequent, *JMJ 1302.*

Ludwigia alterniflora L., pine flatwoods, occasional, *DJR 1272.*

Ludwigia decurrens Walt., forest swales, occasional, *DJR 1707.*

Ludwigia linearis Walt., pine flatwoods, infrequent, *DJR 1257.*

Ludwigia octovalvis (Jacq.) Raven, borrow ditches, frequent, *DJR 1246.*

Ludwigia palustris (L.) Ell., forest swale, infrequent, *DJR 1340.*

Ludwigia pilosa Walt., mixed woods, frequent, *DJR 1653.*

Oenothera laciniata Hill., disturbed roadsides, occasional, *DJR 1403.*

Oenothera speciosa Nutt., disturbed places, occasional, *JMJ 1296.*

OXALIDACEAE

**Oxalis debilis* Kunth, oak hickory ridge, frequent, *DJR 1022.*

Oxalis dillenii Jacq., disturbed roadsides, occasional, *DJR 1382.*

Oxalis stricta L., roadsides, frequent, *JMJ 1254.*

PASSIFLORACEAE

Passiflora lutea L., beech magnolia woods, infrequent, *DJR 1361.*

PHYTOLACCACEAE

Phytolaca americana L., roadsides, waste places, occasional, *JMJ 1330.*

PLANTAGINACEAE

**Plantago lanceolata* L., disturbed areas, infrequent, *DJR 1427.*

**Plantago major* L., roadsides, frequent, *DJR 958.*

Plantago virginica L., roadsides, frequent, *DJR 1077.*

POLYGALACEAE

Polygala cruciata L., bogs, frequent, *GMC s.n.*

Polygala incarnata L., pine savanna, frequent, *JMJ 1324.*

Polygala leptocaulis Torr. & A. Gray, pine savanna, infrequent, *DJR 1115.*

Polygala lutea L., pine savanna, occasional, *JMJ 1219.*

Polygala ramosa Ell., pine savanna, infrequent, *DJR 1118.*

POLYGONACEAE

Brunnichia ovata (Walt.) Shinners, mixed woodls, frequent, *DJR 1362.*

Polygonum caespitosum Bl., swales in oak hickory ridge, frequent, *DJR 929.*

Polygonum densiflorum Meisn., floodplain swamps, frequent, *DJR 1739.*

Polygonum hydropiperoides Michx., mesic swales in oak hickory ridge, occasional, *DJR 1111.*

Polygonum punctatum Ell., fresh marsh, borrow ditches frequent, *DJR 908.*

ACKNOWLEDGMENTS

We are grateful to James Harris, Charlotte Parker, Elizabeth Souheaver, and other staff members with the Southeast Louisiana Refuge Complex for their assistance, enthusiasm, and financial support. Special thanks to James Joyner who made many collections and assisted with fieldwork during the early months of this project, and Gary Couret and Todd Miller for their companionship afield. It is a pleasure to thank Anne Bradburn and Steve Darwin at Tulane University for their assistance. The following botanists provided determinations for various specimens; Joseph Wipff (Poaceae), Billie Turner (Asteraceae and Fabaceae), Guy Nesom (Asteraceae), Roland Roberts (Euphorbiaceae and Asteraceae), Kevin Nixon (*Quercus*), James Phipps (*Crataegus*), Bill Reese (*Lycopodium*), and Robert F. C. Naczi (*Carex*). The review and comments of Barney Lipscomb, Charles Allen, and an anonymous reviewer were very helpful in preparing the final manuscript presented here. Our thanks to Ms. Anna Edwards (USFWS) for preparing figure one.

ABSTRACT

A floristic inventory of the 3,755-ha Thurmond Ranch and immediate vicinity, located in southern Roger Mills County, Oklahoma, was conducted in 2001. Because of its unusual geologic and topographic setting, which has given rise to a heterogeneous environment and long history of human habitation, the site has been the subject of intense archeological and paleoclimatological research since the early 1980s. The inventory documented 85 families, 286 genera, and 470 species of vascular plants in the study area. The five most species-rich families, Asteraceae, Poaceae, Fabaceae, Euphorbiaceae, and Cyperaceae, collectively account for 51% of the species. Non-native species constitute 10% of the total flora. Four North American species probably were introduced by Euro-Americans, and Native Americans may have introduced three species. Populations of four species tracked by the Oklahoma Natural Heritage Inventory were discovered, and *Epilobium leptophyllum* is reported for the first time in Oklahoma. Collection data show a marked floristic difference between the Tertiary Ogallala Formation and the Permian redbeds along the ecotone. Nineteen major vegetation alliances were identified based on observational data, including three woodland alliances, seven shrubland alliances, and eight herbaceous alliances. Mixed-grass prairie plant communities dominate the study area landscape.

RESUMEN

Se realizó un inventario florístico de las 3,755-ha del Thurmond Ranch y alrededores, localizado en el sur del condado de Roger Mills, Oklahoma, en 2001. Debido a las inusuales características geológicas y topográficas, que dieron lugar a un ambiente heterogéneo y larga historia de ocupación humana, el lugar ha sido objeto de intensa investigación arqueológica y paleoclimatológica desde principio de los 1980. El inventario documentó 85 familias, 286 géneros, y 470 especies de plantas vasculares en el área de estudio. Las cinco familias más ricas, Asteraceae, Poaceae, Fabaceae, Euphorbiaceae, y Cyperaceae, tienen conjuntamente el 51% de las especies. Las especies no nativas comprenden el 10% de la flora total. Cuatro especies norteamericanas fueron introducidas probablemente por Euro-Americanos, y los nativos americanos puede que hayan introducido tres especies. Se descubrieron

SIDA 20(3): 1217–1245. 2003

poblaciones de cuatro especies seguidas por el Oklahoma Natural Heritage Inventory, y *Epilobium leptophyllum* se cita por primera vez en Oklahoma. Los datos de colección muestran una clara diferencia florística entre la formación terciaria de Ogallala y las capas sedimentarias rojizas del pérmico a lo largo del ecotono. Se identificaron diecinueve alianzas de vegetación basadas en datos de observación, que incluyen tres alianzas arbóreas, siete arbustivas, y ocho herbáceas. Las comunidades mixtas de pradera dominan el paisaje del área de estudio.

INTRODUCTION

The name "Dempsey Divide" was coined by Thurmond (1990) to refer to the uplands between the Washita and North Fork of the Red Rivers in western Oklahoma. Unusual geologic and topographic conditions in the area have given rise to a heterogeneous environment, an ecology and biota that are distinctive in the southern Great Plains, and a long history of human habitation. Consequently, the Dempsey Divide has been the subject of intense archeological and paleoclimatological research since the early 1980s (Bement 2000; Bement & Buehler 1994, 1998; Buehler 1997; Thurmond 1990, 1991a, 1991b, 1991c, 1997; Thurmond & Picarella 1999; Thurmond et al. 1998; Thurmond & Wyckoff 1998, 1999, 2001). To complement that work, a floristic investigation of the Dempsey Divide was conducted in 2001. The primary objective was to document all native and naturalized vascular plants growing in the area. A secondary objective was to gather baseline data about the plant communities present. This paper summarizes the results of that work.

Study Area

Most of the research described here was conducted on the Thurmond Ranch, a 3,755-ha, contiguous block in southern Roger Mills County, Oklahoma (Fig. 1). The ranch is southwest of Cheyenne, the county seat, and is situated at the southeast edge of the High Plains physiographic province (Bruner 1931). It is on the north side of the Dempsey Divide and extends from the crest of the divide northward to the edge of the Washita River valley.

Brokenleg, Plum, and Sergeant Major Creeks, three short, north-flowing, steep-gradient tributaries of the Washita River, drain the western, northern, and central parts of the ranch, respectively. Killough Creek and Higgins Creek, tributaries of Sergeant Major Creek, traverse the eastern part. These streams have incised a dense, dendritic drainage network on the north side of the divide, creating a canyon system characterized by arroyo cut-and-fill cycles (Schumm & Hadley 1957) operating on centennial and millennial time scales. The most recent incision cycle began around the turn of the 20th Century, triggered by the intense land use of the early post-1892 white settlement period. Maximum elevation on the ranch is 732 m above sea level in the southwest corner. Miminum elevation is 601 m in the northeast corner along Sergeant Major Creek.

The climate of west-central Oklahoma is continental and typified by marked seasonal variation (Curry 1970). Annual annual precipitation at Elk City, roughly 25 km southeast of the ranch, is 57 cm (Oklahoma Climatological

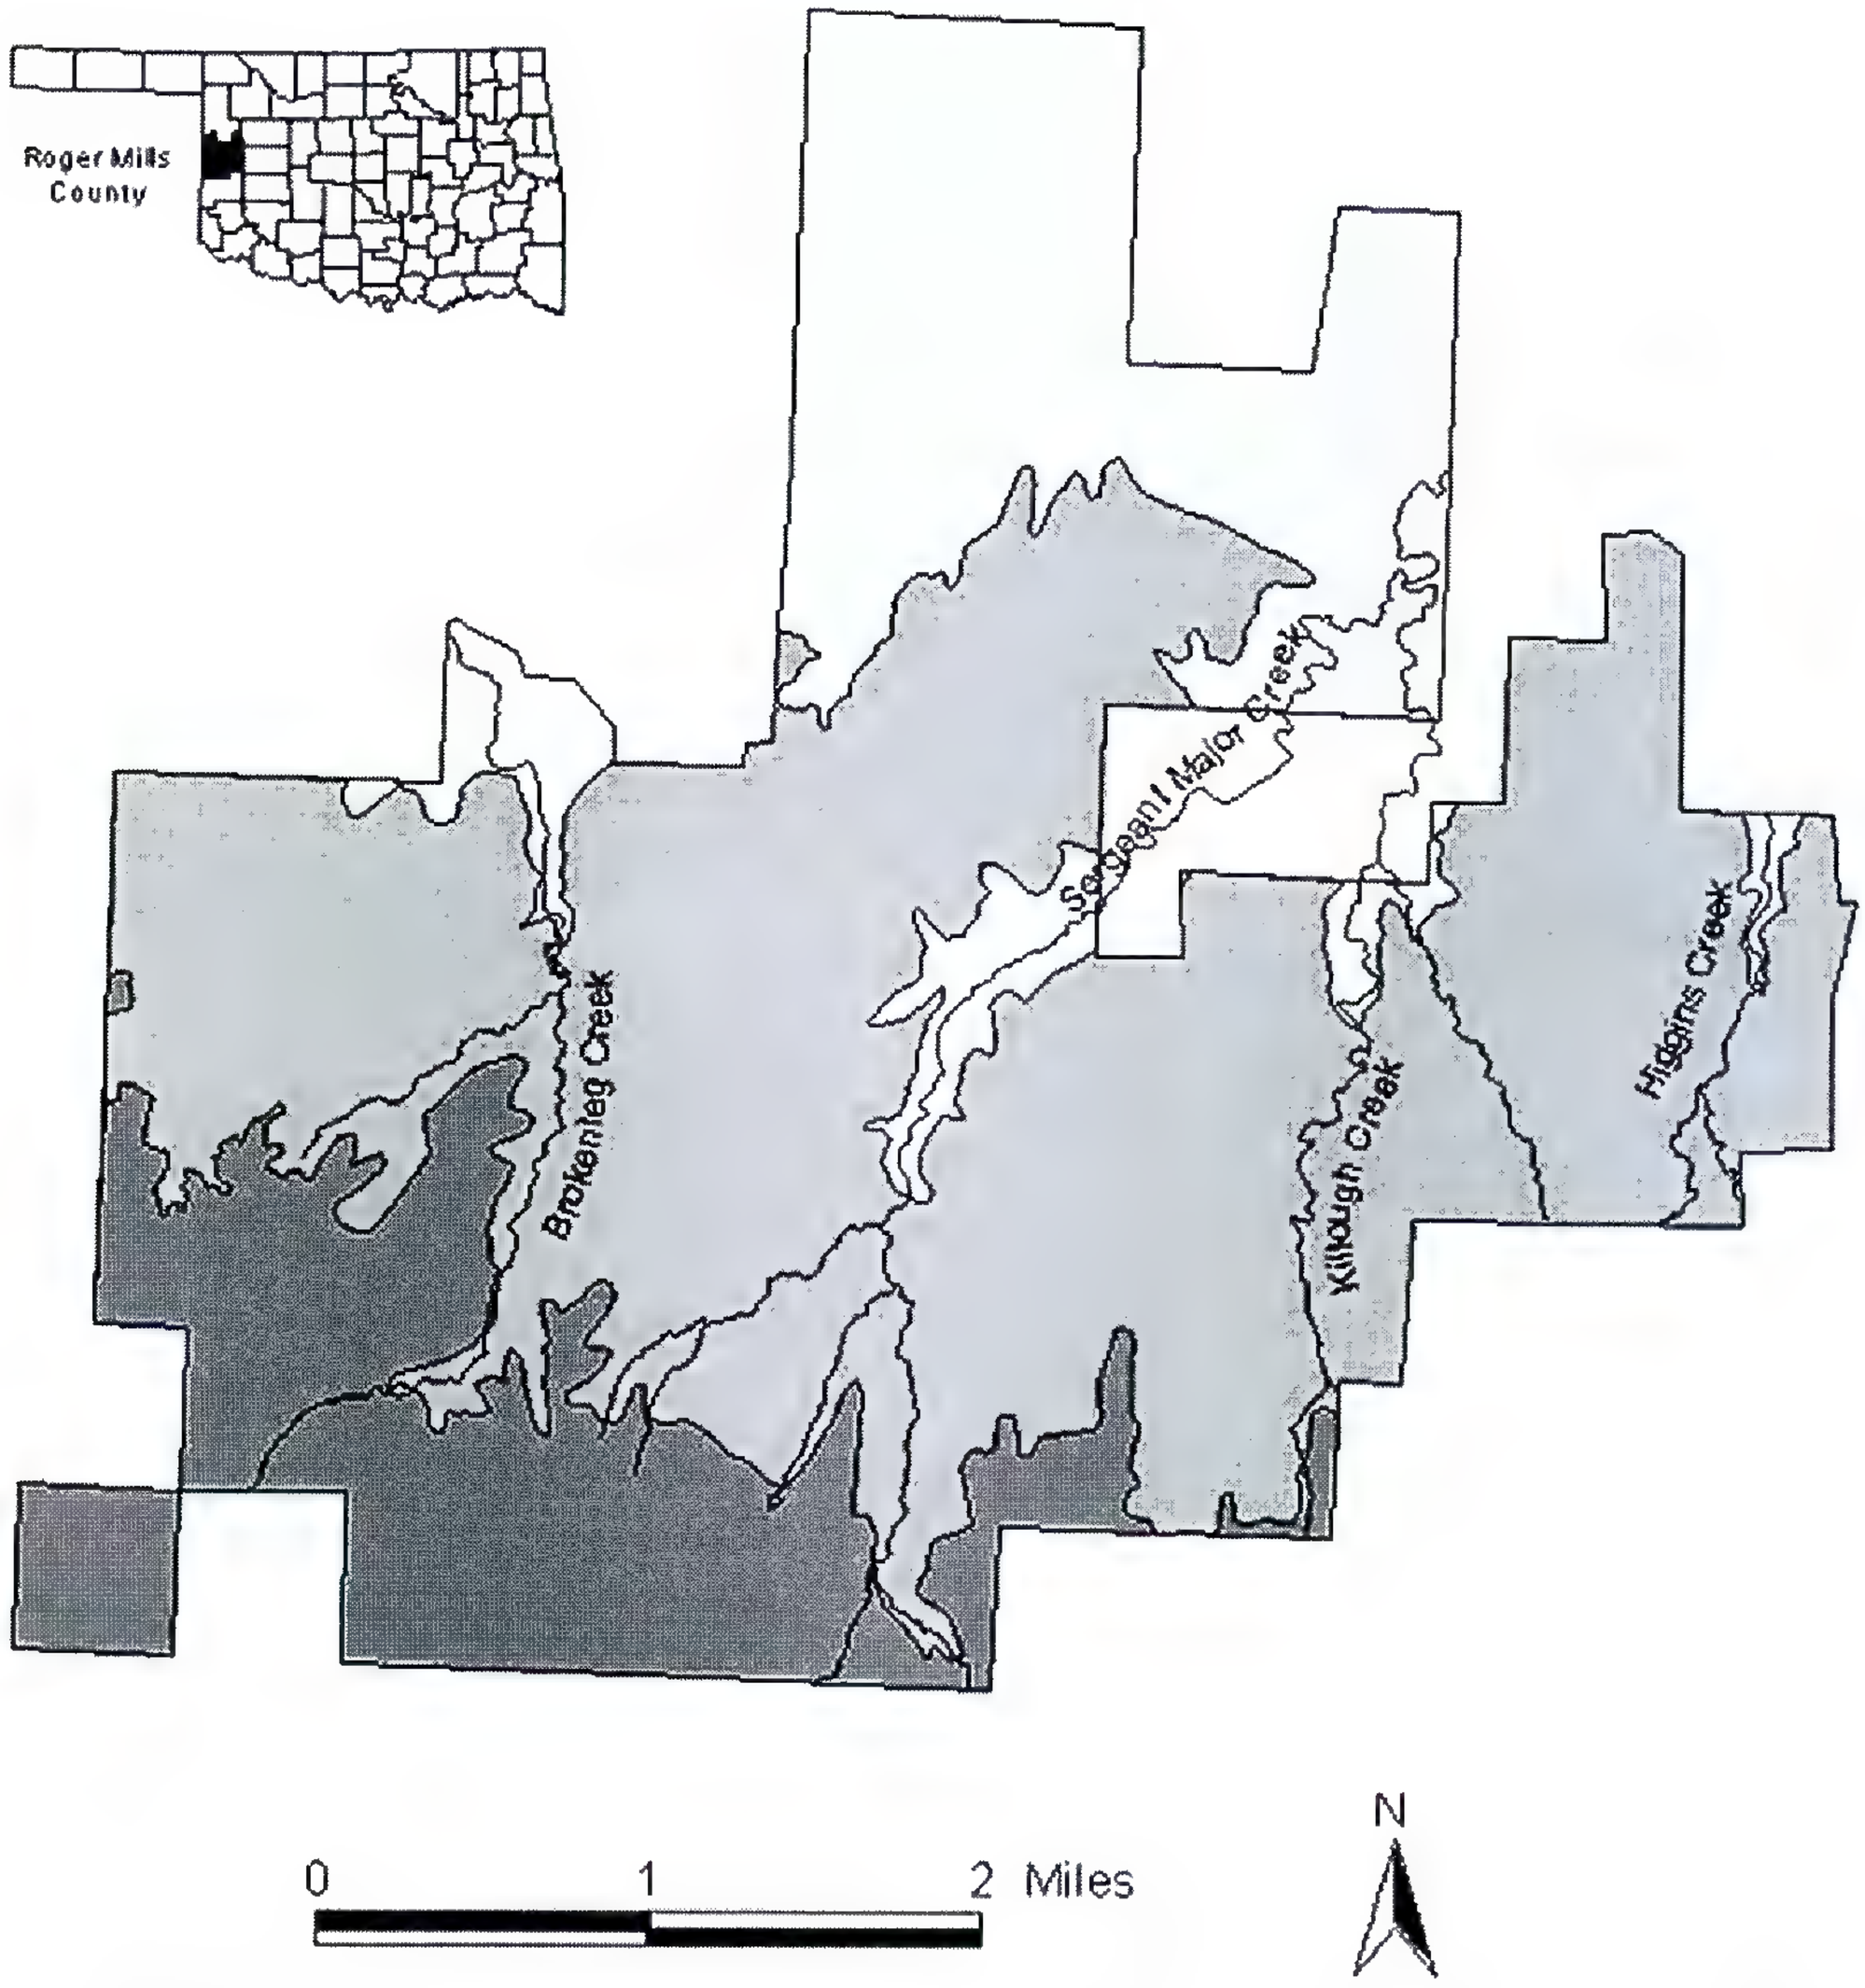

FIG. 1. The Thurmond Ranch, Roger Mills County, Oklahoma. **Dark gray** = Ogallala Formation, **gray** = Doxey Shale Formation, **light gray** = Cloud Chief Formation.

Survey 2002). More than 75% of the annual precipitation occurs from April through October, and precipitation is most abundant in May (12 cm) and least abundant in January (2 cm). Average annual temperature at Elk City is 15.8° C. Average January temperature is 2.3° C and average July temperature is 27.7° C. The average frost-free growing season is approximately 208 days (Curry 1970).

The ranch straddles a major geological and ecological boundary—the eastern outcrop edge of the Ogallala Formation, referred to here as the Ogallala ecotone. Three major geological formations occur on the Dempsey Divide on the ranch: the Tertiary period Ogallala Formation, and the Permian period Doxey Shale and Cloud Chief formations (Fig. 1). Thurmond et al. (2002) discuss the

geomorphology of each formation, but because differences among them have profoundly affected the local topography, vegetation, and history of human use, a brief summary follows.

The Ogallala Formation comprises late Miocene- and Pliocene-age, alluvial outwash from the Rocky Mountains. Its coarse sediments were deposited across the western Great Plains by braided streams, many of which arose in the Rocky Mountains where they were fed by episodically intense rainfall (Frye & Leonard 1957; Gustavson & Finley 1985; Gutentag et al. 1984; Reeves & Reeves 1996; Ryder 1996; Seni 1980). Much of the lower Ogallala is extremely sandy. It forms a gently rolling landscape atop the Dempsey Divide and was significantly reworked by wind into dunes and deflation basins in the late Pleistocene (Thurmond & Wyckoff 1998).

The Doxey Shale comprises discontinuous claystone and sandy siltstone beds deposited during the Permian period on a tropical coastal floodplain. It generally is dense, fine textured, and resists downward percolation of groundwater. Consequently, many streams leading off the Ogallala Formation are spring fed at the Ogallala-Doxey Shale contact. Seeps and small springs do occur in the Doxey Shale outcrop, but only in particularly wet years. The Doxey Shale is fairly resistant to erosion, and its outcrop is typified by deep canyonlands.

Beneath the Doxey Shale is the Permian Cloud Chief Formation (Carr & Bergman 1976), which comprises soft, finely laminated sandstone with thin layers of interbedded gypsum. The Cloud Chief erodes more evenly and readily than does the Doxey Shale, yielding a more gently rolling topography. Upon transition from the Doxey Shale to the Cloud Chief, slope gradients decrease dramatically and stream valleys broaden.

Geologically, the Ogallala ecotone is an unstable and dynamic landscape. Deposition of the Ogallala Formation ended in the Late Pliocene, and the eastern edge of the formation has been eroding episodically westward since. The outcrop edge on the ranch is estimated to have retreated more than 1.5 km since the end of the last glaciation, 15,000–10,000 years B.P. (Thurmond & Wyckoff 2001).

The complex geology and intensely dissected terrain on the north side of the Dempsey Divide have yielded a patchwork of soils. Deep, calcareous, coarse-textured mollisols dominate on the Ogallala and have a much higher effective precipitation than do soils on the Permian outcrops. Extensive exposures of weathering bedrock characterize the Doxey Shale, except where gully fills have facilitated the development of isolated alfisols, inceptisols, and mollisols. These same soil types achieve greater expression on the more gentle landscape of the Cloud Chief outcrop, but evaporites discourage plant growth in many eroded areas (Thurmond et al. 2002).

The geological and topographical setting of the Dempsey Divide has pro-

vided unusual environmental conditions for the development of the region's biota. Diverse terrestrial, palustrine, and riverine natural communities interdigitate along the Ogallala ecotone, and humans have long taken advantage of the natural resources available in this environment. A remarkable concentration of hunter-gatherer campsites is associated with the ecotone, and it has been inferred that these sites were situated to make most efficient use of the diverse floral and faunal communities along this boundary (Thurmond 1990, 1991b).

Human occupation of the Ogallala ecotone on the Dempsey Divide has not been continuous over time. Prehistoric habitation was most intense during the particularly wet periods of the 10th and 2nd millennia before present (Thurmond & Wyckoff 2001). Settlement by Euro-Americans began in earnest in the late 1800s. Between the 1890s and the early 1900s, homesteaders exploited the landscape for crop and livestock production. Approximately 17% (630 ha) of the ranch was farmed, and cattle and horses intensively grazed the rest. Homesteaders began to leave around 1915, and the Thurmond family purchased most of the land composing the ranch between 1915 and 1950. The last of the cultivated land was reseeded to grass in the early 1960s, and land use has been limited to low-intensity grazing by cattle since that time. Deep drilling for natural gas has caused localized disturbance since the late 1970s. Erosion on the ranch has been controlled by revegetation efforts and the construction of erosion control structures (Thurmond et al. 2002).

METHODS

Four major collecting trips were made during 2001 by two of the authors (CCF and CAM): 24–25 April, 30 May–1 June, 23–26 July, and 2–4 October. Sites with vegetation representative of the major vegetation alliances on each of the three major geologic formations were visited during each trip. For most species, at least one voucher was collected on each formation on which it was encountered. Information was recorded about the abundance of species and the vegetation alliances in which they occurred. Opportunistic collecting by one of the authors (JPT) and by Hillary Loring of the Kansas Biological Survey netted additional specimens. A complete set of vouchers is deposited in the R.L. McGregor Herbarium (KANU), University of Kansas. Duplicate specimens for many collections are deposited in the Robert Bebb Herbarium (OKL), University of Oklahoma.

Presence/absence data were recorded in a species × geological formation matrix. These data were used to compare the floras of the formations using Dice's coefficient for 1) all species and 2) native species only. Coefficients were obtained using SPSS 9.0 (SPSS Inc. 1998).

Major vegetation alliances tentatively were identified using observational data. Dominant species, associated species, and habitat data were used to identify alliances following the hierarchical classification of Hoagland (2000).

RESULTS AND DISCUSSION

General Characteristics of the Flora

More than 1,400 numbers (3,100 specimens including duplicates) were collected in the study area. These represent 85 families, 286 genera, and 470 species of vascular plants (Table 1). Four additional species were documented in the study area (Thurmond et al. 2002), but vouchers for these were not verified at KANU so they are excluded from this list. The five most species-rich families are Asteraceae (81, 5 non-native), Poaceae (77, 20 non-native), Fabaceae (44, 3 non-native), Euphorbiaceae (19), and Cyperaceae (17). These five families collectively account for 51% of the species currently known in the study area.

Non-natives compose 10% of all of the species documented. The vast majority of these are Eurasian species introduced accidentally or intentionally since the time of Euro-American settlement. *Campsis radicans*, *Carya illinoinensis*, *Catalpa speciosa*, and *Maclura pomifera*, although native to Oklahoma, likely were introduced intentionally by homesteaders. Native Americans may have introduced three other species (*Acorus calamus*, *Echinochloa muricata*, and *Juglans nigra*) in the study area; Thurmond et al. (2002) discuss these taxa in detail. Among the five largest families in the study area, introduced species are proportionally highest in the Poaceae (26%). Three families (Acoraceae, Bignoniaceae, and Tamaricaceae) and 32 genera are represented by non-native species only. Non-native species dominate one plant community on the ranch: the aquatic *Nasturtium officinale* herbaceous alliance.

Populations of four species tracked by the Oklahoma Natural Heritage Inventory (Oklahoma Natural Heritage Inventory 2001) were discovered during the inventory: *Echinocereus reichenbachii*, *Eriogonum alatum*, *Monarda pectinata*, and *Zinnia grandiflora*. All grow on rocky, mixed-grass prairies on the ranch, except *Monarda pectinata*, which is confined to sand prairies and sandsage shrublands.

Epilobium leptophyllum is reported for the first time in Oklahoma. This herbaceous perennial grows in fens, marshes, and seeps throughout the northern and central Great Plains (Great Plains Flora Association 1991) southward to Meade County, Kansas (Great Plains Flora Association 1977). A small population on a seepy, open slope near the Ogallala-Doxey Shale contact is 180 km south-southeast of the nearest Kansas population (Freeman et al., in press).

The number of species documented on each of the three formations in the study area is summarized in Figure 2. Nearly 900 occurrences (species × formation combinations) were recorded. Despite the fact that all collections were made during a single growing season, these records provide insights into the general floristic patterns in the study area.

Thirty percent of all species (140) were documented on all three formations, but there is a clear floristic difference on either side of the Ogallala ecotone (the

TABLE 1. Numerical summary of the vascular flora of the Ogallala ecotone on the Dempsey Divide.

Group	Families	Genera	Species		
			Native	Non-native	Total
Pteridophytes	2	2	2	0	2
Gymnosperms	1	1	2	0	2
Angiosperms	82	283	418	48	466
Monocots	13	61	89	21	110
Dicots	69	222	329	27	356
Total	85	286	422	48	470

Tertiary/Permian outcrop boundary). Floristic similarity, as estimated by Dice's coefficient (D) using all species, was greater between the Cloud Chief and Doxey Shale formations (D = 0.764) than between the Cloud Chief and Ogallala formations (D = 0.625) or the Doxey Shale and Ogallala formations (D = 0.577). The same calculation using native species only yielded slightly higher coefficients but congruent results (D = 0.785 for Cloud Chief and Doxey Shale, D = 0.626 for Cloud Chief and Ogallala, D = 0.594 for Doxey Shale and Ogallala). Twenty-five percent of all species (119) were found only on the Ogallala. A large majority of these are psammophytes. Mesophytes and hydrophytes account for roughly 25% of the Ogallala-only species. Non-native species are distributed roughly proportionally to the species richness of each of the formations (Fig. 2).

Vegetation Alliances

Nineteen vegetation alliances are recognized, but accurate identification and characterization of all alliances, as well as finer resolution of association-level patterns, must await further studies. Given the dearth of vegetation studies for western Oklahoma (Hoagland 2000), future work likely will be useful in refining the existing state vegetation classification.

Woodland Alliances.—A woodland is defined as an open stand of trees with crowns not usually touching and canopy coverage of 25–60% (Hoagland 2000). Structural diversity often is less than in a forest, and trees usually are taller than 5 m (Lauver et al. 1999). Three woodland alliances were identified on the ranch: the *Sapindus saponaria* woodland alliance, the *Populus deltoides* woodland alliance, and the *Salix nigra* woodland alliance. All three occur along riparian corridors, especially on the lower Doxey Shale and on the Cloud Chief formations. Woodland alliances are best developed along the mainstems of Brokenleg, Plum, and Sergeant Major Creeks, but they also extend up the larger tributaries and occur near springs and seeps at the Ogallala-Doxey Shale contact.

Celtis reticulata, *Juglans microcarpa*, *Juniperus virginiana*, *Robinia pseudoacacia*, *Sideroxylon lanuginosum*, and *Ulmus americana* are common trees in these alliances. *Cornus drummondii*, *Forestiera pubescens*, *Rhus*

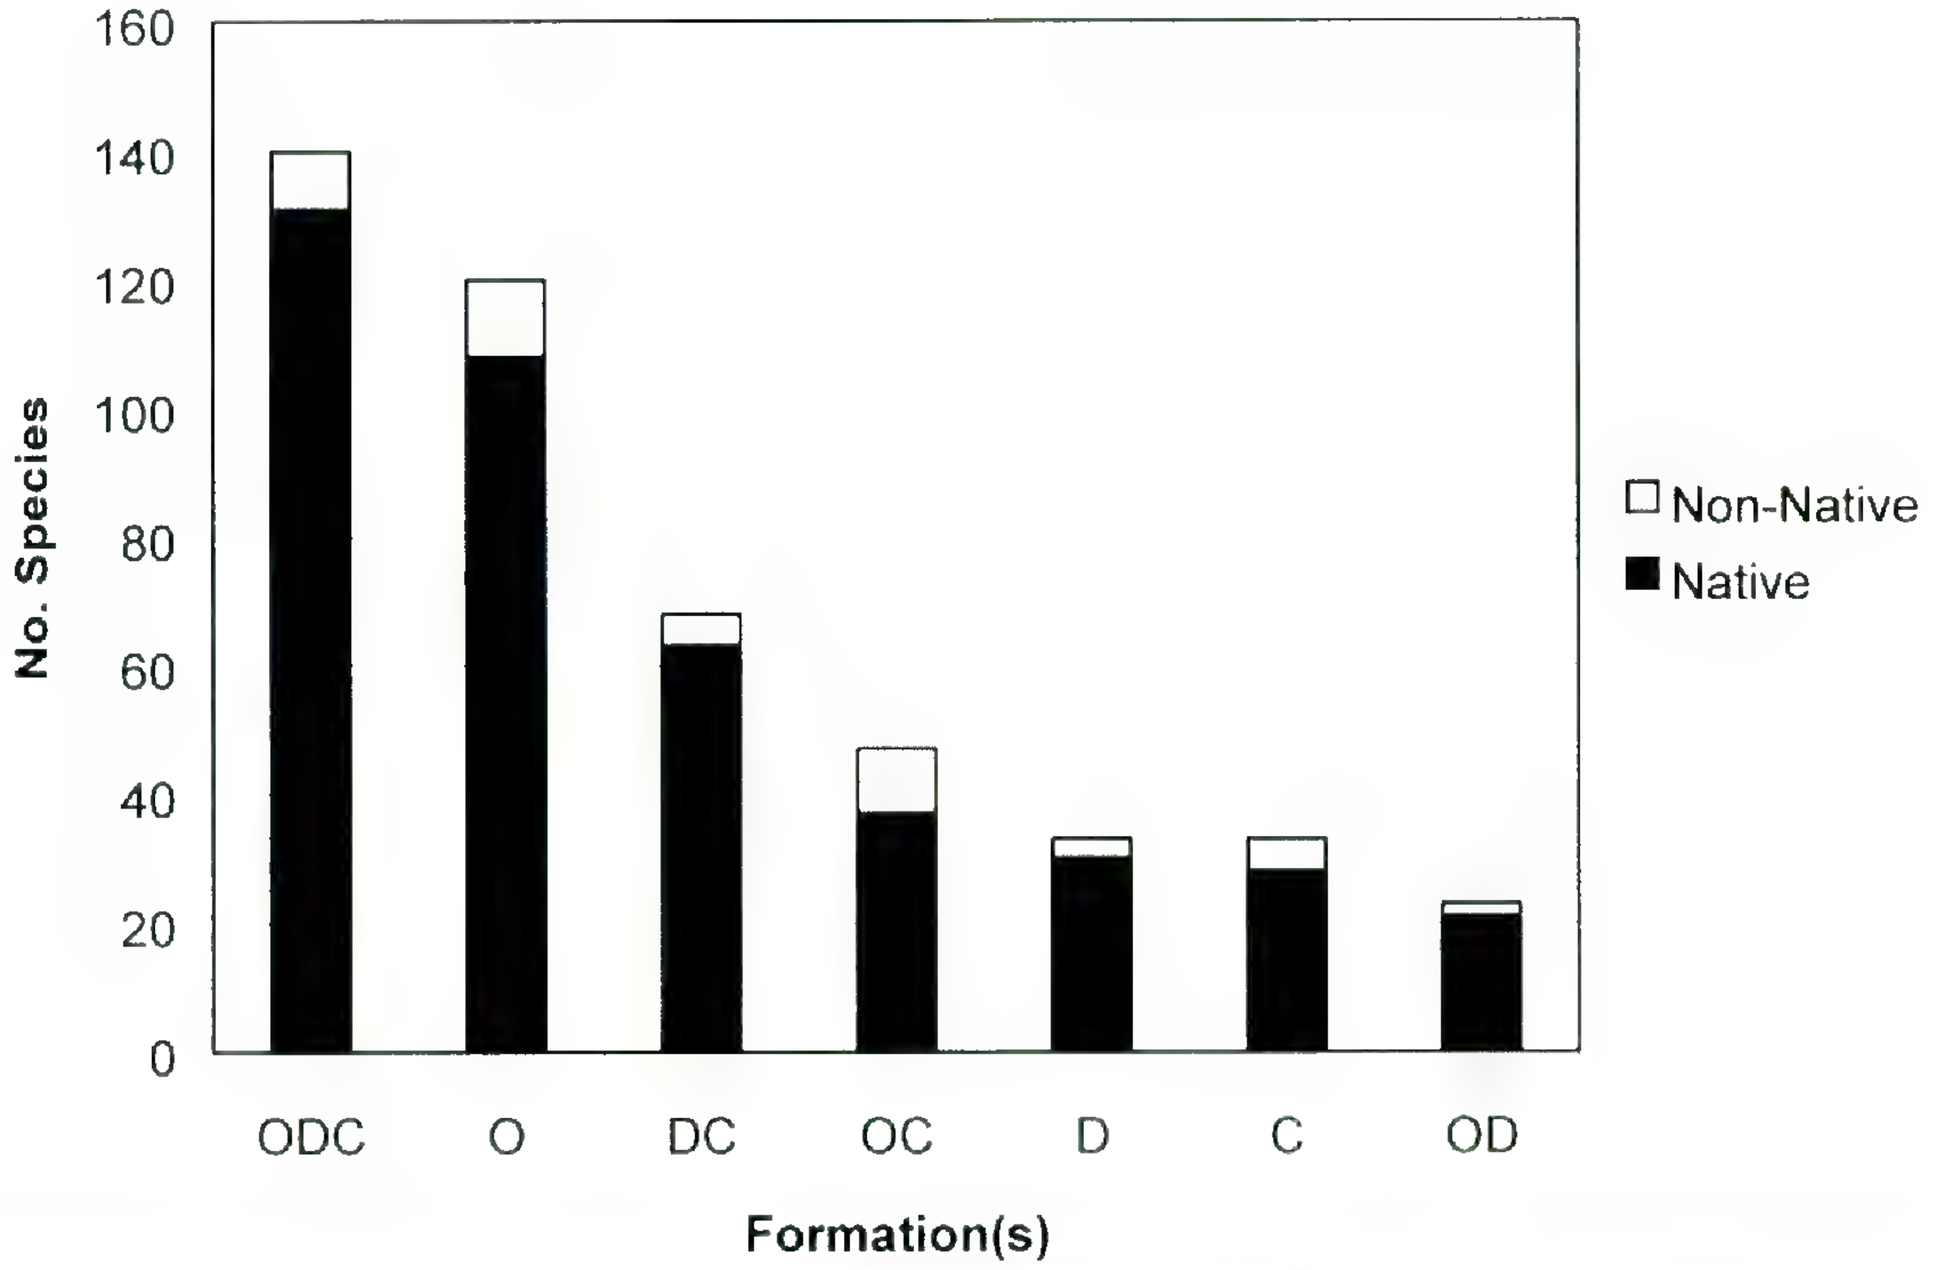

FIG. 2. Species occurrence by formation. **O** = Ogallala; **D** = Doxey Shale; **C** = Cloud Chief.

aromatica, *Rhus glabra*, and *Salix exigua* are typical shrub elements, with *Ampelopsis cordata*, *Parthenocissus quinquefolia*, *P. vitacea*, *Toxicodendron radicans*, and *Vitis acerifolia* the most common woody vines. Representative herbaceous species include *Carex austrina*, *C. bulbostylis*, *C. gravida*, *Chenopodium simplex*, *C. standleyanum*, *Elymus canadensis*, *E. virginicus*, *Galium aparine*, *G. circaezans*, *Geum canadense*, *Phytolacca americana*, and *Sanicula canadensis*. Species restricted to woodland habitats near the Ogallala-Doxey Shale contact are *Bidens bipinnatus*, *Botrychium virginianum*, and *Rubus bushii*.

Shrubland Alliances.—Shrubs or trees 0.5–5 m tall dominate a shrubland, individuals or clumps do not touch or overlap, shrub canopy cover generally is greater than 25%, and tree canopy cover is less than 25% (Hoagland 2000; Lauver et al. 1999). Seven shrubland alliances were identified on the ranch. Some upland sites on the Doxey Shale and Cloud Chief formations support large populations of *Mimosa borealis*, and this likely represents an undescribed, xerophytic, deciduous, shrubland alliance.

The *Quercus havardii* shrubland alliance and the *Artemisia filifolia* shrubland alliance are largely confined to deep dunes and alluvial sands above the Ogallala Formation. *Quercus havardii* and *Artemisia filifolia* are the dominant shrubs, respectively. *Sporobolus cryptandrus* and *Schizachyrium scoparium* are codominant graminoids in both alliances. Characteristic species in both types are *Ambrosia psilostachya*, *Amphiachyris dracunculoides*, *Andropogon hallii*, *Artemisia ludoviciana*, *Bouteloua curtipendula*, *B. hirsuta*, *Calylophus*

serrulatus, *Cenchrus spinifex*, *Chamaesyce glyptosperma*, *Croptilon hookerianum*, *Cyperus lupulinus*, *C. schweinitzii*, *Dalea candida*, *D. enneandra*, *Eriogonum annuum*, *E. longifolium*, *Liatris punctata*, *Machaeranthera pinnatifida*, *Mentzelia nuda*, *Mimosa borealis*, *Paronychia jamesii*, *Plantago patagonica*, *Prionopsis ciliata*, *Rhus aromatica*, *Stenosiphon linifolius*, *Thelesperma megapotamicum*, *Xanthisma texanum*, and *Yucca glauca*.

Two other shrubland alliances, the *Prunus angustifolia* alliance and the *Rhus aromatica* alliance, frequently are found on the Ogallala Formation, but they also occur in sandy, gravelly, or silty sites on Permian substrates. *Schizachyrium scoparium* occurs as a codominant in the former type and is a regular associate in the latter. Other associates include *Andropogon hallii*, *Bouteloua curtipendula*, *Croptilon hookerianum*, *Eriogonum annuum*, *Plantago patagonica*, *Prionopsis ciliata*, *Prunus gracilis*, *Rhus aromatica*, *Toxicodendron radicans*, and *Vitis acerifolia*.

Three shrubland alliances occur along streams and shorelines of ponds and reservoirs: the *Salix exigua* alliance, *Cephalanthus occidentalis* alliance, and *Tamarix chinensis*[= *Tamarix ramosissima*] alliance. Associates in all three types are *Aster subulatus*, *Baccharis salicina*, *Distichlis spicata*, *Panicum virgatum*, *Polygonum lapathifolium*, *Pascopyrum smithii*, *Pluchea odorata*, and *Populus deltoides*.

Herbaceous Alliances.—Herbaceous plants, usually with at least 25% cover, dominate the herbaceous alliances. Trees and shrubs form less that 25% cover (Hoagland 2000; Lauver et al. 1999). Herbaceous alliances, which include grasslands, are the predominant vegetation in the study area. Eight herbaceous alliances were identified on the ranch, five of which are grassland types.

The *Andropogon hallii* herbaceous alliance, called sand prairie, is a tall sod grassland alliance. The best examples occur on deep dune sands atop the Ogallala Formation, with isolated occurrences on well-drained, sandy or gravelly soils on the Permian substrates. *Artemisia filifolia*, *Prunus angustifolia*, *Quercus havardii*, and *Rhus aromatica* are typical shrubs. The sand prairie shares many of the herbaceous associates found in the *Quercus havardii* shrubland alliance and the *Artemisia filifolia* shrubland alliance. Additional associates are *Aristida purpurascens*, *Froelichia floridana*, *F. gracilis*, *Gaura villosa*, *Lechea tenuifolia*, *Oenothera rhombipetala*, *Penstemon buckleyi*, and *Polygonum tenue*.

Medium-tall sod grassland types, called mixed-grass prairies, dominate the northern three-quarters of the ranch on Permian substrates. Three types were identified: the *Bothriochloa laguroides* herbaceous alliance, *Schizachyrium scoparium-Bouteloua curtipendula* herbaceous alliance, and *Bouteloua curtipendula* herbaceous alliance. Additional work is needed to determine the extent and composition of these alliances, which share many species. *Gutierrezia sarothrae* and *Mimosa borealis* are characteristic shrubs. Herbaceous associates include *Allium drummondii*, *Ambrosia psilostachya*,

Ammoselinum popei, *Amphiachyris dracunculoides*, *Aristida purpurea*, *Artemisia ludoviciana*, *Aster ericoides*, *A. falcatus*, *A. fendleri*, *Bothriochloa ischaemum*, *Bouteloua curtipendula*, *B. hirsuta*, *Buchloë dactyloides*, *Callirhoë involucrata*, *Castilleja purpurea*, *Chaetopappa ericoides*, *Chamaesyce fendleri*, *Cirsium ochrocentrum*, *C. undulatum*, *Croton texensis*, *Dalea candida*, *D. enneandra*, *Eriogonum alatum*, *E. longifolium*, *Gaura coccinea*, *Grindelia squarrosa*, *Lesquerella gordonii*, *L. ovalifolia*, *Liatris punctata*, *Linum rigidum*, *Lygodesmia juncea*, *Machaeranthera pinnatifida*, *Penstemon albidus*, *Plantago patagonica*, *Schedonnardus paniculatus*, *Schizachyrium scoparium*, *Sporobolus compositus*, *S. cryptandrus*, *Stenosiphon linifolius*, *Tetraneuris scaposa*, *Thelesperma megapotamicum*, *Vulpia octoflora*, *Xanthisma texanum*, and *Yucca glauca*.

Two other grassland alliances occur along streams, shorelines of ponds and reservoirs, and marshes. Intermittently flooded habitats support the *Pascopyrum smithii* herbaceous alliance. Typical associates include *Aster subulatus*, *Cyperus odoratus*, *Echinochloa crusgalli*, *E. muricata*, *Hordeum jubatum*, *Muhlenbergia asperifolia*, *Phyla lanceolata*, *P. nodiflora*, *Pluchea odorata*, *Polypogon monspeliensis*, and *Schoenoplectus pungens*. Semipermanently flooded areas support the *Scirpus pungens* (misapplied as *Schoenoplectus americanus* in Hoagland [2000] and many earlier floristic works) herbaceous alliance. Associates are *Ammannia coccinea*, *Aster subulatus*, *Distichlis spicata*, *Cyperus odoratus*, *Echinochloa crusgalli*, *E. muricata*, *Eleocharis coloradoensis*, *E. macrostachya*, *E. montevidensis*, *E. rostellata*, *Fuirena simplex*, *Leersia oryzoides*, *Muhlenbergia asperifolia*, *Phalaris caroliniana*, *Poa arida*, *Juncus torreyi*, *Phyla nodiflora*, *Pluchea odorata*, *Potentilla paradoxa*, *Ranunculus cymbalaria*, *R. sceleratus*, *Rumex altissimus*, *Setaria parviflora*, and *Typha domingensis*.

The *Lesquerella* (*gordonii*, *ovalifolia*) herbaceous alliance occurs on rock outcrops and rocky or gravelly slopes on the Doxey Shale and Cloud Chief formations. Generally, perennial forbs contribute greater than 50% of the total herbaceous cover in this alliance. Typical associates include *Artemisia campestris*, *Bouteloua curtipendula*, *B. hirsuta*, *Hedeoma drummondii*, *Hedyotis nigricans*, *Heterotheca stenophylla*, *Krameria lanceolata*, *Oenothera macrocarpa*, *Schizachyrium scoparium*, *Scutellaria resinosa*, and *Tetraneuris scaposa*.

The *Nasturtium officinale* herbaceous alliance is found around springs and along spring runs. It is dominated by hydromorphic, rooted vegetation that grows in permanently flooded environments. Associates are *Eleocharis montevidensis*, *Leersia oryzoides*, *Muhlenbergia asperifolia*, and *Schoenoplectus pungens*. The abundance and persistence of many other species appear to depend on local microhabit conditions.

Disturbed or degraded uplands on Permian formations often are similar to Hoagland's (2000) *Amphiachyris dracunculoides* herbaceous alliance. Char-

acteristic species of this annual grassland alliance are *Ambrosia psilostachya*, *Aristida oligantha*, *A. purpurea*, *Bothriochloa ischaemum*, *B. laguroides*, *Bouteloua curtipendula*, *B. hirsuta*, *Bromus japonicus*, *Chloris verticillata*, *Eragrostis curvula*, *Schizachyrium scoparium*, and *Sporobolus cryptandrus*.

Ruderal Sites.—Natural and semi-natural vegetation alliances typically contain areas in which the native vegetation is disturbed as a result of localized or widespread environmental or biological perturbations. Non-native species often colonize these ruderal sites, and in some cases, aggressive non-natives may spread and severely affect native plant communities. Parts of the ranch were cultivated prior to 1915, but all such areas have since been reseeded to native grasses and forbs. Many non-native species occupy these formerly cultivated sites. Other non-native species are found on the ranch around old farmsteads and newer building sites, along the shoulders of ranch roads, in corrals, and in sites where cattle congregate.

The most frequent non-natives in ruderal sites are *Aegilops cylindrica*, *Bothriochloa ischaemum*, *B. laguroides*, *Bromus catharticus*, *B. japonicus*, *Cynodon dactylon*, *Echinochloa crusgalli*, *Eragrostis curvula*, *Lactuca serriola*, *Medicago minima*, *Melilotus alba*, *M. officinalis*, *Rumex crispus*, *Salsola tragus*, *Setaria viridis*, *Sorghum halepense*, *Taraxacum laevigatum*, and *Tragopogon dubius*.

ANNOTATED CHECKLIST

Family names are arranged alphabetically within three major groups: pteridophytes, gymnosperms, and angiosperms. Genera, species, and infraspecific taxa are arranged alphabetically within each family. Nomenclature for scientific names and common names follows Freeman (2002). Names used in the Atlas of the Flora of the Great Plains (Great Plains Flora Association 1977) and Flora of the Great Plains (Great Plains Flora Association 1991) but synonymized in Freeman (2002) are identified as "A" and "F", respectively. Additional notes clarify nomenclatural issues for some species. An asterisk (*) identifies non-native species as identified by the Great Plains Flora Association (1991) and Freeman (2002).

Relative frequency of each species on the ranch is estimated from the number of populations seen by the authors using a slightly modified version of the scale proposed by Palmer et al. (1995): abundant (**5**) = dominant or codominant in one or more plant alliances; frequent (**4**) = easily seen or found in one or more plant alliances (e.g., mixed-grass prairie or woodland) but not dominant in any plant alliances; occasional (**3**) = widely scattered but not difficult to find in one or more plant alliances; infrequent (**2**) = difficult to find with few individuals or colonies but found in several locations in one or more plant alliances; and rare (**1**) = very difficult to find and limited to one or few populations in one or more plant alliances.

Alliance data for each species are summarized by major habitat types as follows: **w** = woodlands (including riparian woodlands); **s** = sandy complex (including sand prairies, sandsage shrublands, and shinnery oak shrublands); **m** = mixed-grass prairies (including clayey, silty, sandy, gravelly, and rocky mixed-grass prairies, rock outcrops, and rocky slopes); **p** = palustrine communities (including seeps and marshes); **r** = riverine sites (including spring runs and streams); **l** = lacustrine communities (including ponds and reservoirs); and **u** = ruderal sites (including abandoned homesites, roadsides, and well sites).

Geologic formations from which specimens were collected, or in a few cases observed but not collected, are designated for each taxon by the following abbreviations: **O** = Tertiary Ogallala, **D** = Permian Doxey Shale, and **C** = Permian Cloud Chief. Collection numbers for voucher specimens are cited after any synonyms. Abbreviations for collector names are **F** (Craig C. Freeman), **L** (Hillary Loring), **M** (Caleb A. Morse), and **T** (J. Peter Thurmond).

PTERIDOPHYTES

EQUISETACEAE

Equisetum laevigatum A. Braun, Smooth scouring rush, 2; p,r; O. F16890

OPHIOGLOSSACEAE

Botrychium virginianum (L.) Sw., Rattlesnake fern, common grape fern, 1; w,p; O. MF5973

GYMNOSPERMS

CUPRESSACEAE

Juniperus pinchotii Sudw., Pinchot juniper, 1; m; D. F16865, FM17942

Juniperus virginiana L. var. *virginiana*, Eastern redcedar, 3; w,m; O,D,C. F16935, FM17689, FM17811, MF6386

ANGIOSPERMS

ACANTHACEAE

Ruellia humilis Nutt., Fringe-leaf wild-petunia, 2; s; O. MF6061

ACORACEAE

**Acorus calamus* L., European sweetflag, 1; p,r; O. MF5982

AGAVACEAE

Yucca glauca Nutt., Small soapweed, 4; s,m; O,D,C. MF6186, MF6406, MF6421, MF6435, MF6501

ALISMATACEAE

Echinodorus berteroi (Spreng.) Fassett, Upright burhead, 2; l; D,C. [*E. rostratus* (Nutt.) Engelm. ex A. Gray – A, F] FM17798, FM17881

AMARANTHACEAE

Amaranthus albus L., Tumbleweed amaranth, 2; l,u; O,D,C. FM17821, FM17930, FM18404

Amaranthus arenicola I.M. Johnst., Sandhill pigweed, 1; s; O. FM17698

Amaranthus blitoides S. Watson, Prostrate pigweed, 4; u; O,D,C. [*A. graecizans* L. – A, F] FM17603, FM17905, FM18339, MF6014, MF6170, MF6210

Amaranthus palmeri S. Watson, Palmer's pigweed, 1; u; O,D. L2001-51, MF6462

Amaranthus retroflexus L., Rough pigweed, Red root pigweed, 1; u; O,D,C. FM17929, MF6392, MF6463

Froelichia floridana (Nutt.) Moq., Field snake-cotton, 2; s; O. FM17714

Froelichia gracilis (Hook.) Moq., Slender snake-cotton, 2; s,m; O. FM17657, MF6487

ANACARDIACEAE

Rhus aromatica Aiton var. *pilosissima* (Engelm.) Shinners, Fragrant sumac, 2; w,m; C. FM17521

Rhus aromatica Aiton var. *serotina* (Greene) Rehder, Fragrant sumac, 3; w,m; O,D,C. F16875, FM17662, MF5950, MF6277

Rhus aromatica Aiton var. *trilobata* (Nutt.) A. Gray, Fragrant sumac, 1; m; D. MF6137

Rhus glabra L., Smooth sumac, 3; w,s,m; O,D,C. FM17590, L2001-23, MF5945, MF6136, MF6278

Toxicodendron radicans (L.) Kuntze subsp.

negundo (Greene) Gillis, Poison-ivy, 3; w,s,m; O,D,C. F16899, FM17769, MF6397

Toxicodendron rydbergii (Small ex Rydb.) Greene, Rydberg's poison-ivy, Western poison-ivy, 1; w,s; O. FM17663

APIACEAE

Ammoselinum popei Torr. & A. Gray, Plains sand-parsley, 4; m; D,C. F16863, F16901, F16921, MF6258

Cymopterus macrorhizus Buckley, Big-root spring-parsley, 2; m; D,C. F16850, F16930, F16945

Lomatium foeniculaceum (Nutt.) J.M. Coult. & Rose var. *daucifolium* (Nutt.) Cronquist, Fennel-leaf desert-parsley, 2; m; D,C. F16849, F16951

Sanicula canadensis L. var. *canadensis*, Canadian sanicle, 3; w; D,C. FM17869, MF5934, MF6366

Spermolepis inermis (Nutt.ex DC.) Mathias & Constance, Spreading scaleseed, Western scaleseed, 2; s; O,D. MF6004, MF6124, MF6473

* *Torilis arvensis* (Huds.) Link, Field hedge parsley, 2; w,u; D,C. MF6352, MF6364

APOCYNACEAE

Apocynum cannabinum L., Hemp dogbane, Prairie dogbane, 3; m,p; O,D,C. FM17735, MF5955, MF6133, MF6275

ASCLEPIADACEAE

Asclepias asperula (Decne.) Woodson subsp. *capricornu* (Woodson) Woodson, Antelope horn milkweed, 3; s,m; O,D,C. [*A. asperula* (Decne.) Woodson var. *decumbens* (Nutt.) Shinners – A, F] MF6050, MF6103, MF6222

Asclepias engelmanniana Woodson, Engelmann's milkweed, 3; s,m; O,D,C. FM17541, FM17666, FM17779, FM18396, FM18483, FM18484, MF6140, MF6412

Asclepias latifolia (Torr.) Raf., Broad-leaf milkweed, 3; s,m; O,D. FM17906, FM18321

Asclepias stenophylla A. Gray, Narrow-leaf milkweed, 1; s; O. MF6066

Asclepias tuberosa L. subsp. *interior* Woodson, Butterfly milkweed, 2; s; O. MF6008, MF6441

Asclepias viridiflora Raf., Green milkweed, 3; s,m; O,D,C. FM17593, FM17702, FM17907, MF6002, MF6144, MF6285, MF6449

Asclepias viridis Walter, Spider milkweed, 1; s; O. FM17672

ASTERACEAE

Ambrosia psilostachya DC., Western ragweed, 4; s,m; O,D,C. FM17604, FM17775, FM17873, FM18264, FM18299, FM18393

Ambrosia trifida L., Giant ragweed, 1; w,u; O,C. FM18325, FM18472

Amphiachyris dracunculoides (DC.) Nutt., Common broomweed, 5; s,m; O,D,C. [*Gutierrezia dracunculoides* (DC.) S.F. Blake – A, F] FM17904, FM17934, FM18263, FM18309, FM18409

Aphanostephus skirrhobasis (DC.) Trel. var. *skirrhobasis*, Parasol lazy-daisy, 2; s; O. MF6026, MF6439

Artemisia campestris L. subsp. *caudata* (Michx.) H.M. Hall & Clem., Western sagewort, 2; s,m; O. FM18307

Artemisia dracunculus L., Silky wormwort, Tarragon, 2; m; D. FM18395, FM18420, L2001 118

Artemisia filifolia Torr., Sand sagewort, 5; s,m; O,D,C. FM17626, FM17836, FM18340, FM18475

Artemisia ludoviciana Nutt. var. *ludoviciana*, Louisiana sagewort, 4; s,m; O,D,C. FM 17522, FM17899, FM17926, FM18265, FM18394, FM18459

Aster ericoides L. subsp. *ericoides* var. *ericoides*, Heath aster, White aster, 3; s,m; O,D,C. FM18266, FM18268, FM18305, FM18408

Aster falcatus Lindl. subsp. *commutatus* (Torr. & A. Gray) A.G. Jones, Western heath aster, 3; m,p; O,D,C. FM18362, FM18416, FM18457

Aster fendleri A. Gray, Fendler's aster, 3; m; D,C. FM18267, FM18407, FM18417, L2001-16

Aster oblongifolius Nutt., Aromatic aster, 2; s,m; O,D. FM18306b, FM18363, FM18418

Aster patens Aiton var. *patentissimus* (Lindl. ex DC.) Torr. & A. Gray, Sky-drop aster, 2; s; O. FM17576, FM18306a

Aster subulatus Michx. var. *ligulatus* Shinners, Saltmarsh aster, 4; p,r,l; O,D,C. FM17767, FM18361, FM18428, FM18449

Baccharis salicina Torr. & A. Gray, Willow baccharis, 3; p,r,l; O,D,C. FM17639, FM17721, FM17761, FM17841, FM17868

Berlandiera betonicifolia (Hook.) Small, Betony-leaf berlandiera, 2; s; O. [*B. texana* DC. – A, F] MF6077, MF6431

Echinacea angustifolia DC. var. *angustifolia*, Narrow-leaf coneflower, 2; m,s; O,C. FM17528, FM17611, MF6065

Eclipta prostrata (L.) L., Yerba de tajo, 2; r,l; O,D,C. FM17588, FM17754, FM18439

Engelmannia peristenia (Nutt. ex Rydb.) Goodman & C.A. Lawson, Engelmann daisy, 3; m,s; O,D,C. [*E. pinnatifida* Nutt. – A, F] FM17664, MF6149, MF6272

Erigeron modestus A. Gray, Plains fleabane, 2; m; D,C. F16875, F16932, FM18399, MF6131, MF6316, MF6346

Erigeron strigosus Muhl. ex Willd., Daisy fleabane, 3; m,s; O,D,C. MF6068, MF6130, MF6302

Eupatorium perfoliatum L., Clasping leaf joe-pye weed, Boneset, 2; p,r; O. FM17719, FM18328

Euthamia gymnospermoides Greene, Sticky euthamia, 1; r; O. [*Solidago graminifolia* (L.) Salisb. var. *gymnospermoides* (Greene) Croat – A; *S. graminifolia* (L.) Salisb. var. *media* (Greene) S.K. Harris – A] FM18349

Evax prolifera Nutt. ex DC., Big-head rabbit-tobacco, 2; m,s; O,D,C. F16898, FM17755, MF6238, MF6354, MF6470

Gaillardia pulchella Foug. var. *pulchella*, Indian blanket-flower, Rose-ring blanket-flower, 3; m; O,D,C. MF6027, MF6094, MF6212

Gaillardia suavis (A. Gray & Engelm.) Britton & Rusby, Rayless blanket-flower, 2; m; D,C. MF6127, MF6232

Grindelia squarrosa (Pursh) Dunal var. *nuda* (A.W. Wood) A. Gray, Curly-top gumweed, 3; s,m,u; O,D,C. FM17921, FM18271, FM18312

Gutierrezia sarothrae (Pursh) Britton & Rusby, Broom snakeweed, 4; s,m; O,D,C. FM17894, FM18274, FM18301, FM18405, L2001-20

Helianthus annuus L., Common sunflower, 2; u; O,D,C. FM17693, FM17772, FM18380, FM18482, L2001-101

Helianthus maximilianii Schrad., Maximilian's sunflower, 1; w; C. Ts.n.

Helianthus petiolaris Nutt. subsp. *petiolaris*, Plains sunflower, 2; s,m; O,C. FM17586, FM18308, L2001-79, MF6028

Helianthus tuberosus L., Jerusalem-artichoke sunflower, 1; p, O,C. L2001-56

Heterotheca latifolia Buckley var. *macgregoris* B. Wagenkn., Broad-leaf golden-aster, 3; s,m; O,D,C. FM17606, FM17918, FM18304, L2001-76

Heterotheca stenophylla (A. Gray) Shinners var. *angustifolia* (Rydb.) Semple, Narrow-leaf golden-aster, 3; m; O,D,C. [*Chrysopsis villosa* (Pursh) Nutt. ex DC. var. *angustifolia* (Rydb.) Cronquist – A, F] FM17530, FM17807, FM18310

Heterotheca stenophylla (A. Gray) Shinners var. *stenophylla*, Narrow-leaf golden-aster, 2; s,m; O,D. [*Chrysopsis stenophylla* (A. Gray) Shinners – A, F] FM17838, FM17919, MF6486

Hymenopappus tenuifolius Pursh, Chalk-hill woolly-white, 3; s,m; O,D,C. FM17629, FM17898, MF6011, MF6122, MF6206, MF6419, MF6442

Lactuca ludoviciana (Nutt.) Ridd., Western lettuce, Louisiana lettuce, 1; w; C. MF6378

**Lactuca serriola* L., Prickly lettuce, 2; u; O,D. FM17632, FM17791, FM17796

Liatris punctata Hook., Western dotted

gayfeather, 4; s,m; O,D,C. FM17893, FM18275, FM18311, FM18411, L2001-14

Liatris squarrosa (L.) Michx. var. *glabrata* (Rydb.) F.C. Gates, Plains gayfeather, 2; s; O. [*L. glabrata* Rydb. – A] FM17580

Lindheimera texana A. Gray & Engelm., Texas-star, 1; m; C. MF6314

Lygodesmia juncea (Pursh) D. Don ex Hook., Rush skeleton weed, 3; m; C. FM18270, FM18481, MF6292

Machaeranthera pinnatifida (Hook.) Shinners var. *glaberrima* (Rydb.) B.L. Turner & R.L. Hartm., Cut-leaf tansy-aster, 4; s,m; O,D,C. [*Haplopappus spinulosus* (Pursh) DC. subsp. *glaberrimus* (Rydb.) H.M. Hall – F] FM17834, MF6071, MF6090, MF6234

Machaeranthera pinnatifida (Hook.) Shinners var. *pinnatifida*, Cut-leaf tansy-aster, 2; m; D,C. [*Haplopappus spinulosus* (Pursh) DC. subsp. *australis* (Greene) H.M. Hall – F; *H. spinulosus* (Pursh) DC. subsp. *cotula* (Small) H.M. Hall – F; *H. spinulosus* (Pursh) DC. subsp. *spinulosus* – A, F] MF6085, MF6207

Melampodium leucanthum Torr. & A. Gray, Plains blackfoot, 3; m; D,C. F16949, FM18270, FM18392, MF6099, MF6260, MF6409

**Onopordum acanthium* L., Scotch thistle, 1; w,u; D,C. MF6330

Packera plattensis (Nutt.) W.A. Weber & Á. Löve, Prairie ragwort, 3; m; O,D,C. [*Senecio plattensis* Nutt. – A, F] F16845

Plectocephalus americanus (Nutt.) D. Don, American knapweed, Basket-flower, 3; m; D,C. [*Centaurea americana* Nutt – A, F] FM17553, FM17849, FM17936, MF6146, MF6291

Pluchea odorata (L.) Cass., Purple marsh-fleabane, 4; r,l; O,D,C. [*P. purpurascens* (Sw.) DC. – A] FM17638, FM17876, FM18365, FM18448, L2001-29

Prionopsis ciliata (Nutt.) Nutt., Wax-goldenweed, 4; s; O,C. [*Haplopappus ciliatus* (Nutt.) DC. – A, F] FM17718, FM18272, FM18298

Pseudognaphalium obtusifolium (L.) Hilliard & B.L. Burtt, Fragrant false-cudweed, 1; u; O. [*Gnaphalium obtusifolium* L. – A, F] FM18343

Psilostrophe tagetina (Nutt.) Greene var. *cerifera* (A. Nelson) B.L. Turner, Marigold paper-flower, 1; m; C. [*P. villosa* Rydb. – A, F] MF6337

Pyrrhopappus grandiflorus (Nutt.) Nutt., Tuberous false-dandelion, 2; s,m; O,D,C. F16848, MF6037, MF6107, MF6195

Ratibida columnifera (Nutt.) Wooton & Standl., Upright prairie-coneflower, 2; s,m; O,D,C. MF6036, MF6125, MF6263

Senecio riddellii Torr. & A. Gray, Riddell's grounsel, 3; s,m; O,D. FM18302, FM18415

Solidago altiplanities C.E.S. Taylor & R.J. Taylor, High-plains goldenrod, 3; m; O,D,C. FM17557, FM18273, FM18300, FM18403, FM18419

Solidago canadensis L. var. *scabra* (Muhl. ex Willd.) Torr. & A. Gray, Canadian goldenrod, 2; w,p,r; O,C. FM17734, FM18327, FM18446

Solidago gigantea Aiton, Late goldenrod, November goldenrod, 1; w,p,r; O. FM18346

Solidago missouriensis Nutt., Missouri goldenrod, Prairie goldenrod, 2; s,m; O,C. FM17709, FM17877, FM18462, Ts.n.

Solidago petiolaris Aiton var. *petiolaris*, Downy goldenrod, 1; s,m; O,D. FM18372, FM18402

**Sonchus asper* (L.) Hill, Prickly sow-thistle, 2; u; O,C. MF5974, MF6297

**Taraxacum laevigatum* (Willd.) DC., Red-seed dandelion, 2; m,u; O,C. F16913, MF6283

Tetraneuris scaposa (DC.) Greene var. *scaposa*, Naked-stem tetraneuris, 4; m; D,C. [*Hymenoxys scaposa* (DC.) K.L. Parker var. *glabra* (Nutt.) K.L. Parker – A, F; *H. scaposa* (DC.) K.L. Parker var. *scaposa* – A, F] F16825, F16876, F16952, MF6231, MF6418, MF6490

Thelesperma filifolium (Hook.) A. Gray var. *intermedium* (Rydb.) Shinners, Thread-leaf greenthread, 1; m; D. MF6120

Thelesperma megapotamicum (Spreng.) Kuntze, Rio Grande greenthread, 4; s,m; O,D,C. FM17835, MF6074, MF6139, MF6233, MF6417

**Tragopogon dubius* Scop., Western salsify, 2; m,u; O,C. MF6080, MF6267

Verbesina encelioides (Cav.) Benth. & Hook.f. ex A. Gray subsp. *encelioides*, Golden crownbeard, 1; w,u; O. FM18324

Verbesina encelioides (Cav.) Benth. & Hook.f. ex A. Gray subsp. *exauriculata* (B.L. Rob. & Greenm.) J.R. Coleman, Golden crownbeard, 2; u; D. FM18386

Vernonia baldwinii Torr. subsp. *interior* (Small) W.Z. Faust, Western ironweed, 3; s,m; O,D,C. FM17547, FM17585, FM17762, FM17888, FM18421

Xanthisma texanum DC. subsp. *drummondii* (Torr. & A. Gray) Semple, Sleepy daisy, 4; s,m; O,D,C. [*X. texanum* DC. var. *drummondii* (Torr. & A. Gray) A. Gray – A] FM17615, FM17917, FM18313, MF6044, MF6350, MF6451

Xanthium strumarium L., Common cocklebur, 3; I; O,D,C. FM17803, FM18276, FM18377

Zinnia grandiflora Nutt., Rocky Mountain zinnia, 2; m; D,C. MF6095, MF6336, MF6408

BIGNONICACEAE

**Campsis radicans* (L.) Seem., Common trumpet-creeper, Trumpetvine, 1; w,u; O. FM18335

**Catalpa speciosa* Warder, Northern catalpa, Catawba-tree, 2; w,u; O. FM18336, MF5986

BORAGINACEAE

Lappula redowskii (Hornem.) Greene, Flat-spine stickseed, 3; s,m; O,D,C. F16853, F16922, MF5940, MF6293

Lappula texana (Scheele) Britton, Cup-seed stick-seed, 2; s,m; D,C. F16927, F16940

Lithospermum caroliniense (Walter ex J.F. Gmel.) MacMill., Carolina gromwell, Carolina puccoon, 1; s; O. MF6069

Lithospermum incisum Lehm., Plains gromwell, 3; s,m; O,D,C. F16878, F16944, MF6003, MF6154, MF6254, MF6469

BRASSICACEAE

**Camelina microcarpa* Andrz. ex DC., Little-pod false flax, 1; u; C. MF6294, MF6494

**Capsella bursa pastoris* (L.) Medik., Common shepherd's-purse, 2; u; O,D,C. F16838

Descurainia pinnata (Walter) Britton subsp. *halictorum* (Cockerell) Detling, Pinnate tansy-mustard, 2; m,u; O,C. F16880

Dimorphocarpa candicans (Raf.) Rollins, Palmer's spectacle-pod, 1; s; O. [*D. palmeri* (Payson) Rollins – F; *Dithyrea wislizenii* Engelm. var. *palmeri* Payson A] FM17654, MF6424

Draba reptans (Lam.) Fernald, White whitlow-wort, 2; m; O,D,C. F16832

Erysimum asperum (Nutt.) DC., Plains wallflower, 1; m; C. F16948

Lepidium densiflorum Schrad., Prairie pepper-grass, 2; m,u; O,D. F16835, MF6006

Lepidium oblongum Small, Oblong pepper-grass, 2; m,u; D,C. F16836, MF6257

**Nasturtium officinale* R. Br., Common watercress, 1; r; O. F16892, MF5970

Physaria gordonii (A. Gray) O'Kane & Al-Shehbaz, Gordon's bladderpod, 4; m; D,C. [*Lesquerella gordonii* (A. Gray) S. Watson – A, F] F16856, MF6255

Physaria ovalifolia (Rydb.) O'Kane & Al-Shehbaz subsp. *ovalifolia*, Oval-leaf bladderpod, 4; m; O,D,C. [*Lesquerella ovalifolia* Rydb. subsp. *ovalifolia* – A, F] F16847, F16950, MF6404, MF6488

CACTACEAE

Coryphantha vivipara (Nutt.) Britton & Rose var. *vivipara*, Pin-cushion coryphantha, 2; s,m; O,D,C. FM18322, MF6118, MF6331, MF6361

Cylindropuntia imbricata (Haw.) F.M. Knuth var. *imbricata*, Tree cholla, 1; m; C. [*Opuntia imbricata* (Haw.) DC. var. *imbricata* – A, F] FM18485

Echinocereus reichenbachii (Terscheck ex Walp.) F. Haage var. *reichenbachii*, Lace hedgehog cactus, 2; m; D,C. FM17559, MF6192, MF6413

Opuntia macrorhiza Engelm. var. *macrorhiza*, Big-root pricklypear, 3; s,m; O,D,C. FM17560, MF6056, MF6332, MF6362, MF6436

Opuntia phaeacantha Engelm. var. *major* Engelm., New Mexico pricklypear, 1; m; D. FM17852

CAMPANULACEAE

Lobelia cardinalis L., Cardinal-flower, 1; p; O. L2001-61

Triodanis holzingeri McVaugh, Holzinger's Venus'-looking glass, 2; s; O. MF6046, MF6446

Triodanis leptocarpa (Nutt.) Nieuwl., Slender-fruit Venus'-looking-glass, 3; m; D,C. MF6119, MF6235

CAPPARACEAE

Polanisia dodecandra (L.) DC. subsp. *trachysperma* (Torr. & A. Gray) H.H. Iltis, Rough-seed clammyweed, 2; s,m; D,C. MF6298, MF6407

Polanisia jamesii (Torr. & A. Gray) H.H. Iltis, James' clammyweed, Cristatella, 2; s,m; O. [*Cristatella jamesii* Torr. & A. Gray – A] FM17653, FM18282, MF6073, MF6189

CARYOPHYLLACEAE

Loeflingia squarrosa Nutt. subsp. *texana* (Hook.) Barneby & Twisselm., Spreading loeflingia, 1; s; O. MF6062

Paronychia jamesii Torr. & A. Gray, James' nailwort, 4; s,m; O,D,C. FM17525, FM17597, MF6030, MF6110, MF6268, MF6478

Silene antirrhina L., Sleepy catchfly, 3; s,m; O,D,C. F16829, MF6033, MF6161, MF6305, MF6447
**Stellaria pallida* (Dumort.) Crép., Pale chickweed, 1; u; C. F16911

CELASTRACEAE

Celastrus scandens L., American bittersweet, 1; w; C. MF6379

CHENOPODIACEAE

Chenopodium berlandieri Moq. var. *zschackii* (Murray) Murray ex Asch., Pit-seed goosefoot, 3; m,u; O,D. FM17904, FM17931, FM18341, FM18382
**Chenopodium glaucum* L., Oak-leaf goosefoot, 1; l; C. FM18444
Chenopodium missouriense Aellen, Missouri goosefoot, 1; u; C. FM18466
Chenopodium pratericola Rydb., Field goosefoot, 3; s,m; O,D. FM17578, FM17658, FM17776, MF6015, MF6428
Chenopodium simplex (Torr.) Raf., Maple-leaf goosefoot, 2; w; O. [*C. gigantospermum* Aellen – F; *C. hybridum* L. – A] FM17728, FM18332
Chenopodium standleyanum Aellen, Standley's goosefoot, 3; w; O,D,C. FM17682, FM17727, FM17817, FM18333, FM18412, FM18474
Cycloloma atriplicifolium (Spreng.) J.M. Coult., Tumble ringwing, 2; s; O. FM17616, FM18350, MF6013
**Kochia scoparia* (L.) Schrad., Broom kochia, 1; u; C. FM18465
Monolepis nuttalliana (Schult.) Greene, Nuttall's poverty-weed, 3; m,u; D,C. F16908, F16938, MF6200
**Salsola tragus* L., Common Russian-thistle, 3; u; O,D,C. [*S. iberica* Sennen & Pau – A, F] FM17842, FM17940, FM18373

CISTACEAE

Lechea tenuifolia Michx., Narrow-leaf pinweed, 2; s; O. FM17592, FM18315, MF6064

COMMELINACEAE

Commelina erecta L. var. *angustifolia* (Michx.) Fernald, Erect dayflower, 3; s; O. MF5990, MF6024, MF6482
Tradescantia occidentalis (Britton) Smyth & L. Smyth var. *occidentalis*, Western spiderwort, Prairie spiderwort, 3; s,m; O,D,C. MF6029, MF6176, MF6230, MF6444

CONVOLVULACEAE

Convolvulus equitans Benth., Gray bindweed, 1; m; C. MF6199
Evolvulus nuttallianus Schult., Nuttall's evolvulus, 2; m; D,C. FM17529, MF6045, MF6108, MF6199, MF6228
Ipomoea leptophylla Torr., Bush morning-glory, 1; s,m; D. MF6414

CORNACEAE

Cornus drummondii C.A. Mey., Rough-leaf dogwood, 4; w,m; O,D,C. FM17519, FM17661, FM17814, MF5949, MF6123, MF6318

CUCURBITACEAE

Cucurbita foetidissima Kunth, Buffalo gourd, 3; s,m; O,D,C. MF6327, MF6420, MF6461

CUSCUTACEAE

Cuscuta cuspidata Engelm., Cusp dodder, 2; s,m; O,D,C. FM17656, FM18319, L2001-36, L2001-77

CYPERACEAE

Carex austrina Mack., Southern sedge, 2; w,s; O,C. MF6082, MF6395
Carex bulbostylis Mack., Thick-style sedge, 2; w; O,C. [*C. amphibola* Steud. var. *globosa* (L.H. Bailey) L.H. Bailey – Taylor and Taylor (1994)] MF5997, MF6370
Carex gravida L.H. Bailey, Heavy sedge, 3; w,l; O,D,C. F16870, F16887, F16914, MF5943, MF6224, MF6300, MF6358, MF6359, MF6375
Carex pellita Muhl. ex Willd., Woolly sedge, 1; p,r,l; C. [*C. lanuginosa* Michx. – A, F] FM18463
Cyperus acuminatus Torr. & Hook., Tape-leaf flat-sedge, 1; l; O. FM17646
Cyperus lupulinus (Spreng.) Marcks subsp. *lupulinus*, Slender-stem flat-sedge, 2; s,m; O. FM18364, MF5998
Cyperus ×mesochorus Geise, Intermediate flat-sedge, 2; s,m; O. FM17647, MF5599
Cyperus odoratus L., Slender flat-sedge, Rusty flat-sedge, 3; l; O,D,C. FM17640, FM17748, FM17933, F18379, FM18437
Cyperus schweinitzii Torr., Schweinitz's flat-sedge, 2; s,m; O. MF6025, MF6443
Eleocharis coloradoensis (Britton) Gilly, Colorado spike-rush, 4; l; D,C. FM17739, FM17843, FM17855, FM18456
Eleocharis erythropoda Steud., Bald spike-rush, 2; l; O,C. FM17579, FM17859

Eleocharis geniculata (L.) Roem. & Schult., Cluster spike-rush, 1; l; C. [*E. caribaea* (Rottb.) S.F. Blake – A, F] FM17879

Eleocharis macrostachya Britton, Large-spike spike-rush, 4; l; O,D,C. [*E. xyridiformis* Fernald & Brackett – A, F] FM17650, MF6153, MF6357

Eleocharis montevidensis Kunth, Sand spike-rush, 4; p,r,l; O,D,C. FM17717, FM17740, FM17858, MF5971, MF6152, MF6373

Eleocharis palustris (L.) Roem. & Schult., Marsh spike-rush, 1; l; D. [*E. smallii* Britton – A, F] FM17741

Eleocharis rostellata (Torr.) Torr., Beaked spike-rush, 2; p,l; O,C. FM17732, FM17861

Fuirena simplex Vahl var. *aristulata* (Torr.) Kral, Western umbrella-grass, 2; p,r,l; O,D,C. FM17678, FM17759, FM17856

Schoenoplectus pungens (Vahl) Palla var. *longispicatus* (Britton) S.G. Sm., Common threesquare twine-bulrush, 4; p,r,l; O,D,C. [*Scirpus americanus* Pers. – misapplied in A and in Taylor and Taylor (1994); *S. pungens* Vahl – F] FM17716, FM17863, MF5987

EBENACEAE

Diospyros virginiana L., Virginia persimmon, 2; w,p; O,C. FM17725, FM17890

ELATINACEAE

Bergia texana (Hook.) Seub. ex Walp., Texas bergia, 2; l; D,C. FM17800, FM17822

EUPHORBIACEAE

Acalypha ostryifolia Riddell, Rough-pod copperleaf, 1; u; O. FM18330

Chamaesyce fendleri (Torr. & Gray) Small, Fendler's mat-spurge, 4; m; O,D,C. [*Euphorbia fendleri* Torr. & A. Gray – A, F] F16931, FM17552, FM17591, FM17808, MF6098, MF6259

Chamaesyce geyeri (Engelm.) Small, Geyer's mat spurge, 1; s; O. [*Euphorbia geyeri* Engelm. – A, F] FM18356

Chamaesyce glyptosperma (Engelm.) Small, Ridge-seed mat-spurge, 4; s,m; O,D,C. [*Euphorbia glyptosperma* Engelm. – A, F] FM17613, FM17902, FM17941a, FM18280, MF5979, MF6177, MF6299

Chamaesyce maculata (L.) Small, Spotted mat-spurge, 3; l,u; O,D. [*Euphorbia maculata* L. – A, F] FM17621, FM17747, MF5991

Chamaesyce missurica (Raf.) Shinners, Missouri mat-spurge, 2; s,m; D,C. [*Euphorbia missurica* Raf. – A, F] FM17825, MF6402

Chamaesyce nutans (Lag.) Small, Eyebane, Nodding mat spurge, 1; u; O. [*Euphorbia nutans* Lag. – A, F] FM18357

Chamaesyce prostrata (Aiton) Small, Prostrate mat-spurge, 1; u; C. [*Euphorbia prostrata* Aiton – A, F] FM17941b, MF6491

Chamaesyce serpens (Kunth) Small, Round-leaf mat-spurge, 1; l; C. [*Euphorbia serpens* Kunth - A, F] FM17823

Croton glandulosus L. var. *lindheimeri* Müll. Arg., Tropic croton, 2; s,m; O. FM17589, FM18283, MF6433

Croton monanthogynus Michx., One-seed croton, 3; m,s,u; D,C. FM17774, FM17827, FM17896, MF6167

Croton texensis (Klotzsch) Müll. Arg., Texas croton, 3; s,m; O,D,C. FM17538, FM17778, MF6022, MF6168, MF6307

Euphorbia davidii Subils, Western toothed spurge, 3; s,m,u; O,D,C. FM17780, FM17912

Euphorbia longicuris Scheele, Wedge-leaf spurge, 2; m; D,C. F16859, MF6106B, MF6296

Euphorbia marginata Pursh, Snow-on-the-mountain, 3; m; D,C. FM17546, FM17847, FM18279, FM18477

Euphorbia spathulata Lam., Warty spurge, 2; s,m; D,C. MF6106A, MF6236

Stillingia sylvatica L. subsp. *sylvatica*, Queen's-delight stillingia, 2; s; O. FM17655, MF6076

Tragia betonicifolia Nutt., Betony noseburn, 2; s; O. FM17642 , FM17651, MF6047

Tragia ramosa Torr., Catnip noseburn, 3; m; D,C. F16855, FM18410, MF6173, MF6229, MF6405, MF6489

FABACEAE

Acacia angustissima (Mill.) Kuntze var. *hirta* (Nutt.) B.L. Rob., Prairie acacia, 3; s,m; O,D,C. FM17703, FM17923, MF6290, MF6348, MF6471

Amorpha canescens Pursh, Leadplant, 1; s,m; O. FM17610

Amorpha fruticosa L., Bush wild-indigo, 2; m,l; D,C. FM17840, FM17865, MF6317

Astragalus crassicarpus Nutt. var. *crassicarpus*, Ground-plum milk vetch, 2; m; O,D. F16864, MF6081

Astragalus gracilis Nutt., Slender milk-vetch, 2; m; D,C. F16861, MF6092, MF6269

Astragalus lotiflorus Hook., Lotus milk-vetch, 2; m; D,C. F16827, MF6223, MF6343

Astragalus missouriensis Nutt. var. *missouriensis*, Missouri milk-vetch, 2; m; D. F16857, MF6250

Astragalus mollissimus Torr. var. *mollissimus*, Woolly milk-vetch, 2; m; D,C. F16822, MF6247, MF6349

Astragalus nuttallianus DC. var. *austrinus* (Small) Barneby, Small-flower milk-vetch, 1; m; D,C. F16828, F16937

Astragalus plattensis Nutt., Platte River milk-vetch, 2; s,m; O. F16886, MF6055

Baptisia australis (L.) R. Br. var. *minor* (Lehm.) Fernald, Blue wild-indigo, 3; s,m; O,D,C. F16868, F16954, FM17624, MF6191, MF6274

Baptisia bracteata Muhl. ex Elliott var. *leucophaea* (Nutt.) Kartesz & Gandhi, Plains wild-indigo, 4; s,m; O. [*B. bracteata* Muhl. ex Elliott var. *glabrescens* (Larisey) Isley – F; *B. leucophaea* Nutt. – A] F16719, FM17625, MF6075

Chamaecrista fasciculata (Michx.) Greene, Showy partridgepea, 3; s,m; O. [*Cassia chamaecrista* L. – F; *Cassia fasciculata* Michx. – A] FM17587, FM17910, FM18317

Dalea aurea Nutt. ex Pursh, Golden prairie-clover, 3; m; O,D,C. FM17536, FM17752, FM17805

Dalea candida Michx. var. *oligophylla* (Torr.) Shinners, Western prairie-clover, 4; s,m; O,D,C. FM17567, FM17708, FM17832, MF6499

Dalea enneandra Nutt., Nine-anther prairie-clover, 4; s,m; O,D,C. FM17535, FM17601, FM17712, FM17751, FM17806, MF6287, MF6353

Dalea purpurea Vent. var. *arenicola* (Wemple) Barneby, Purple prairie-clover, 1; s; O. MF6007, MF6445

Dalea purpurea Vent. var. *purpurea*, Purple prairie-clover, 3; s,m; O,D,C. FM17537, FM17668, MF6116, MF6288, MF6398, MF6498

Dalea villosa (Nutt.) Spreng. var. *villosa*, Silky prairie-clover, 1; s; O. FM17634

Desmanthus illinoensis (Michx.) MacMill. ex B.L. Rob. & Fernald, Illinois bundle-flower, 2; s,m; O,D,C. FM17524, FM17665, FM17768, FM17874

Desmodium illinoense A. Gray, Illinois tick-clover, 2; w,s; O. FM17695, MF6051, MF6448

Desmodium sessilifolium (Torr.) Torr. & A. Gray, Sessile-leaf tick-clover, 2; s; O. FM17600, FM17925

Gleditsia triacanthos L., Common honey-locust, 1; w; O. MF6000

Glycyrrhiza lepidota Pursh, American licorice, 3; m,r,l; O. FM17608, MF5975

Gymnocladus dioica (L.) K. Koch, Kentucky coffeetree, 2; w,m; C. F16916, FM17819, MF6384

Hedysarum boreale Nutt., Northern sweet-vetch, 1; m; C. FM17540

Indigofera miniata Ort., Western indigo, 3; s; O. [*I. miniata* Ort. var. *leptosepala* (Nutt.) B.L. Turner – A, F] FM17595, MF6010, MF6453

Lespedeza capitata Michx., Round-head bush-clover, 3; s; O. FM17711

Lespedeza stuevei Nutt., Tall bush-clover, Stueve's bush-clover 4; s; O. FM17584, FM18318

**Medicago minima* (L.) L., Prickly medic, 3; m,u; D,C. F16841, F16910, MF6220, MF6344

**Melilotus alba* Medik., White sweet-clover, 2; u; O,C. FM18348, MF6308

**Melilotus officinalis* (L.) Pall., Yellow sweet-clover, 2; u; O,C. MF6205, MF6390, MF6427

Mimosa borealis A. Gray, Fragrant mimosa, 4; s,m; O,D. FM17704, L200-52, MF6086, MF6198

Mimosa quadrivalvis L. var. *nuttallii* (DC.) L.S. Beard ex Barneby, Cat-claw mimosa, 3; s,m; O,D,C. [*Schrankia nuttallii* (DC.) Standl. – A, F] FM17607, MF6128, MF6197, MF6454

Oxytropis lambertii Pursh var. *lambertii*, Lambert's locoweed, 2; m; O,D,C. F16862, FM17526

Pediomelum cuspidatum (Pursh) Rydb., Tall-bread scurfpea, 3; m; D,C. [*Psoralea cuspidata* Pursh – A, F] MF6104, MF6194

Pediomelum digitatum (Nutt.) Isely, Palm-leaf scurfpea, 2; s; O. [*Psoralea digitata* Nutt. var. *digitata* – A, F] FM17574, MF6054

Pediomelum linearifolium (Torr. & A. Gray) J.W. Grimes, Slim-leaf scurfpea, 3; s,m; O,D,C. [*Psoralea linearifolia* Torr. & A. Gray – A, F] FM17558, FM17833, MF6038, MF6084, MF6273

Prosopis glandulosa Torr. var. *glandulosa*, Honey mesquite, 1; m; O,D. FM17561, L2001-112

Psoralidium tenuiflorum (Pursh) Rydb., Narrow leaf scurfpea, 3; s; O. [*Psoralea tenuiflora* Pursh var. *floribunda* (Nutt.) Rydb. – A, F; *P. tenuiflora* Pursh var. *tenuiflora* – A, F] FM17924, MF6023, MF6474

Robinia pseudoacadia L., Black locust, 3; w; O,D,C. F16897, FM18423, MF6313

Strophostyles leiosperma (Torr. & A. Gray) Piper, Slick-seed wildbean, 2; s; O,D. FM17598, FM17797, FM18316, MF6430
Stylosanthes biflora (L.) Britton et al., Two-flower pencil-flower, 1; s; O. FM17572
Tephrosia virginiana (L.) Pers., Goat's-rue, 1; s; O. MF6070
Vicia americana Muhl. ex Willd. var. *minor* Hook., American vetch, 2; m; D. F16874

FAGACEAE

Quercus havardii Rydb., Shinnery oak, 5; s,m; O,D. F16896, F16955, F16956, FM17670, FM17916
Quercus havardii Rydb. × *Quercus stellata* Wangenh., 3; s,m; O. FM17671, L2000-104, L2000 105
Quercus macrocarpa Michx., bur oak, 1; w; O.Ts.n.

FUMARIACEAE

Corydalis aurea Willd. subsp. *occidentalis* (Engelm. ex A. Gray) G.B. Ownbey, Golden fumewort, 1; m; O. F16879

GERANIACEAE

**Erodium cicutarium* (L.) L'Her. ex Aiton, California filaree, 2; u; D,C. F16837, MF6304
Geranium carolinianum L., Carolina crane's bill, 2; s,m,u; O,C. MF5937, MF6262

GROSSULARIACEAE

Ribes odoratum H.Wendl., Buffalo currant, 3; w,m; O. F16891, MF5951

HYDROCHARITACEAE

Najas guadalupensis (Spreng.) Magnus subsp. *guadalupensis*, Common naiad, 4; l; D,C. FM17738, FM17853

IRIDACEAE

Sisyrinchium ensigerum E.P. Bicknell, Sword-leaf blue-eyed grass, 3; w,m; O,D,C. F16858, F16946, MF6261, MF6347, MF6372

JUGLANDACEAE

**Carya illinoinensis* (Wangenh.) K. Koch, Pecan, 1; u; O. L2001-106
Juglans microcarpa Berland., Texas walnut, Little walnut, 4; w,m; O,D,C. FM17692, FM17765, FM18433, FM18461, MF6138, MF6312, MF6385
**Juglans nigra* L., Black walnut, 2; w; O. FM17691, MF5985

JUNCACEAE

Juncus dudleyi Wiegand, Dudley's rush, 2; p,r; O. FM17680, MF5976
Juncus torreyi Coville, Torrey's rush, 3; p,r,l; O,D,C. FM17645, FM17731, FM17743, FM17875

KRAMERIACEAE

Krameria lanceolata Torr., Trailing ratany, Lance-leaf ratany, 3; s,m; O,D,C. FM18374, MF6083, MF6280, MF6351

LAMIACEAE

Hedeoma drummondii Benth., Drummond's false-penny-royal, 3; m; D,C. FM17527, FM17773, FM17892, MF6188
Hedeoma hispida Pursh, Rough false-penny royal, 3; m; O,D,C. F16918, MF6042, MF6111, MF6256
**Lamium amplexicaule* L., Henbit dead-nettle, 1; u; C. F16909
Lycopus americanus Muhl. ex W.P.C. Barton, American water-horehound, 3; p,r,l; O,D,C. FM17636, FM17726, FM17763, FM17889, FM18360, L2001-30
Monarda citriodora Cerv. ex Lag., Lemon bee-balm, 2; m; D,C. FM17932
Monarda clinopodioides A. Gray, Basil bee-balm, 3; m; D,C. MF6091, MF6225
Monarda pectinata Nutt., Plains bee-balm, 2; s; O. MF6472
Monarda punctata L. var. *occidentalis* (Epling) E.J. Palmer & Steyerm., Spotted bee-balm, 2; s; O. MF6015, MF6440
Salvia azurea Michx. ex Lam., Blue sage, Pitcher's sage, 3; m; O,D,C. [*S. pitcheri* Torr. – A] FM17792, FM18278, FM18314, FM18397, FM18422
Scutellaria drummondii Benth. var. *edwardsiana* B.L. Turner, Drummond's skullcap, 1; m; D. MF6162
Scutellaria resinosa Torr., Resinous skullcap, 4; m; O,D,C. F16947, MF6031, MF6098, MF6211, MF6415
Teucrium canadense L. var. *canadense*, American germander, 2; p,r,l; O,C. [*T. canadense* L. var. *virginicum* (L.) Eaton - A] FM17685, FM17884, FM18440
Teucrium laciniatum Torr., Cut-leaf germander, 1; m; D. MF6399

LILIACEAE

Allium canadense L. var. *fraseri* Ownbey, Canadian onion, 2; s,w; O,C. MF6005, MF6374

Allium drummondii Regel, Drummond's onion, 5; m; D. F16824, F16939
Nothoscordum bivalve (L.) Britton, Yellow false-garlic, 1; m; D. F16840

LINACEAE

Linum berlandieri Hook. var *berlandieri*, Berlandier's flax, 2; m; O,C. [L. *rigidum* Pursh var. *berlandieri* (Hook.) Torr. & A. Gray – A, F] F16925, FM17565
Linum pratense (Norton) Small, Norton's blue flax, 4; m; D,C. F16831, F16926, MF6410, MF6500
Linum rigidum Pursh var. *rigidum*, Stiff-stem flax, 4; m; D,C. F16936, MF6143, MF6163

LOASACEAE

Mentzelia decapetala (Pursh) Urb. & Gilg., Ten-petal mentzelia, 1; m; D,C. FM17846
Mentzelia nuda (Pursh) Torr. & A. Gray, Bractless mentzelia, Sand-lily, 4; s,m; O,D,C. FM17543, FM17568, FM17705, FM17815, FM18480
Mentzelia oligosperma Nutt. ex Sims, Stick-leaf, Chickenthief, 1; m; D. MF6400

LYTHRACEAE

Ammannia coccinea Rottb., Purple toothcup, 3; l; D. FM17648, FM17801
Ammannia robusta Heer & Regel, Stout toothcup, 2; l; O,D,C. FM17746, FM17883

MALVACEAE

Callirhoë involucrata (Torr. & A. Gray) A. Gray var. *involucrata*, Winecup, 1; m; D. MF6134
Callirhoë involucrata (Torr. & A. Gray) A. Gray var. *lineariloba* (Torr. & A. Gray) A. Gray, Winecup, 2; m,p; O,C. FM17733, MF5994, MF6196
Sphaeralcea coccinea (Nutt.) Rydb. var. *coccinea*, Scarlet globe-mallow, 2; m; D,C. F16843, F16943, MF6284

MENISPERMACEAE

Cocculus carolinus (L.) DC., Carolina snailseed, 1; p; O. L2001-66

MOLLUGINACEAE

Mollugo verticillata L., Green carpetweed, 3; s,m,u; O,D,C. FM17652, FM17804, FM17826, MF6041

MORACEAE

**Maclura pomifera* (Raf.) C.K. Schneid., Osage-orange, Hedge-apple, 1; w,u; O [see Schambach (2000) for a discussion of the pre-European range of this species in Oklahoma]. FM18337
**Morus alba* L., White mulberry, 1; w; O. MF5953
Morus rubra L., Red mulberry, 1; w; C. FM17872, MF6383

NYCTAGINACEAE

Mirabilis glabra (S. Watson) Standl., Smooth four-o'clock, 2; s; O. FM17614, FM17633
Mirabilis linearis (Pursh) Heimerl var. *linearis*, Narrow-leaf four-o'clock, 3; m; O,D,C. FM17839, FM18464, L2001-09, MF6178, MF6301, MF6422, MF6481

OLEACEAE

Forestiera pubescens Nutt., Downy forestiera, 4; w,s; O,D,C. F16915, FM17628, FM17771, MF6380

ONAGRACEAE

Calylophus berlandieri Spach subsp. *berlandieri*, Berlandier's evening-primrose, 1; s; O. FM 17659, MF6437, MF6438
Calylophus hartwegii (Benth.) P.H. Raven subsp. *pubescens* (A. Gray) Towner & P.H. Raven, Hartweg's evening-primrose, 3; m; D,C. F16904, F16941, MF6096, MF6202
Calylophus lavandulifolius (Torr. & A. Gray) P.H. Raven, Lavender leaf evening-primrose, 1; m; D. MF6089
Calylophus serrulatus (Nutt.) P.H. Raven, Plains yellow evening-primrose, 4; s,m; O,D,C. FM17548, FM17850, MF6009, MF6072, MF6113, MF6201
Epilobium leptophyllum Raf., American marsh willowherb, Slender-fruit willowherb, 1; p,l; O. FM18359
Gaura coccinea Pursh, Scarlet butterfly-weed, 3; m; D,C. F16833, F16902, MF6239
Gaura parviflora Douglas, Velvet butterfly-weed, 3; s,m,u; O,D,C. FM17631, FM17753, FM17830, FM18371, FM18454, MF6185, MF6289
Gaura villosa Torr. subsp. *villosa*, Hairy butterfly-weed, 3; s,m; O. FM17594, FM18370, MF6017, MF6457
Oenothera laciniata Hill, Cut-leaf evening-primrose, 2; s,m; O. F16881, MF5948, MF6483
Oenothera macrocarpa Nutt. subsp. *incana* (A. Gray) W.L. Wagner, Gray evening-primrose, 3; m; D,C. F16854, FM17542, FM17897, MF6129, MF6411
Oenothera rhombipetala Nutt., Four-point evening-primrose, 1; s; O. FM17641
Oenothera triloba Nutt., Stemless evening-primrose, 1; m; C. F16928

Stenosiphon linifolius (Nutt.) Heynh., Stenosiphon, 4; s,m; D,C. FM17534, FM17750, FM17812, FM17935, FM18281, FM18391, MF6102

OXALIDACEAE

Oxalis dillenii Jacq. subsp. *dillenii*, Gray-green wood-sorrel, 2; m,u; O,D,C. F16929, MF6053, MF6345, FM18470

Oxalils violacea L., Violet wood-sorrel, 1; s,m; O,D. F16917

PAPAVERACEAE

Argemone polyanthemos (Fedde) G.B. Ownbey, Plains prickly-poppy, 2; m; O,D. FM18432, MF6058

PEDALIACEAE

Proboscidea louisianica (Mill.) Thell., Common devil's-claw, 1; l,u; D. FM17802

PHYTOLACCACEAE

Phytolacca americana L. var. *americana*, American pokeweed, 3; w,u; O,D. FM17736, FM18414, MF5941

PLANTAGINACEAE

Plantago patagonica Jacq. var. *patagonica*, Woolly plantain, 4; s,m; O,D,C. MF5959, MF6016, MF6112, MF6209, MF6340

Plantago patagonica Jacq. var. *spinulosa* (Decne.) A. Gray, Bristle-bract plantain, 3; s,m; O,D. MF6079, MF6121, MF6339

Plantago rhodosperma Decne., Red-seed plantain, 3; s,m,u; O,D,C. F16924, MF6052, MF6100, MF6208, MF6389

POACEAE

**Aegilops cylindrica* Host, Jointed goat grass, 2; u; D,C. MF6183, MF6245

**Agrostis gigantea* Roth, Spreading redtop, 1; r; O. FM17681

Andropogon hallii Hack., Sand bluestem, 5; s,m; O,D,C. FM17550, FM17784, FM17908, FM17928, FM18293, FM18406, FM18458

Aristida basiramea Engelm. ex Vasey, Fork-tip threeawn, 1; s; O. FM18291, FM18369

Aristida oligantha Michx., Old-field threeawn, 2; s,m,u; O. FM17571, FM17644, FM18289, FM18366

Aristida purpurascens Poir. var. *purpurascens*, Arrow-feather threeawn, 3; s,m; O. FM17700, FM18290

Aristida purpurea Nutt. var. *longiseta* (Steud.) Vasey, Purple threeawn, 1; m; D. [*A. longiseta* Steud. – A; *A. purpurea* Nutt. var. *robusta* (Merr.) A.H. Holmgren & N.H. Holmgren – F] MF6114

Aristida purpurea Nutt. var. *purpurea*, Purple threeawn, 3; s,m; O,D,C. [*A. roemeriana* Scheele – A, F] FM17701, FM17848, MF6049, MF6213, MF6403, MF6477

Aristida purpurea Nutt. var. *wrightii* (Nash) Allred, Purple threeawn, 5; m; O,D,C. [*A. wrightii* Nash – A] FM17533, FM17556, FM17788, MF6181, MF6478

**Avena fatua* L. wild oats 1; u; D. MF6187

**Bothriochloa ischaemum* (L.) Keng var. *songarica* (Rupr. ex Fisch. & C.A. Mey.) Celarier & J.R. Harlan, Turkestan bluestem, 4; s,m,u; O,D,C. [*Andropogon ischaemum* L. var. *songaricus* Rupr. ex Fisch. ex C.A. Mey. – A, F] FM17660, FM17901, FM18384, FM18476, MF5988, MF6335, MF6368

Bothriochloa laguroides (DC.) Herter subsp. *torreyana* (Steud.) Allred & Gould, Silver bluestem, 3; m,u; O,D,C. [*Andropogon saccharoides* Sw. – A; *A. saccharoides* Sw. var. *torreyanus* (Steud.) Hack. – F] FM17555, FM17790, FM17831, MF6021, MF6135, MF6244

Bouteloua curtipendula (Michx.) Nash var. *curtipendula*, Side oats grama, 5; s,m; O,D,C. FM17531, FM17566, FM17789, FM17813, MF6171, MF6310

Bouteloua gracilis (Willd. ex Kunth) Lag. ex Griffiths, Blue grama, 2; m; C. L2001-98, MF6311

Bouteloua hirsuta Lag. var. *hirsuta*, Hairy grama, 4; s,m; O,D,C. FM17539, FM17609, FM17777, MF6172

**Bromus catharticus* Vahl var. *catharticus*, Rescue brome, 3; u; O,D,C. [*B. unilioides* Kunth – A, F] F16839, MF5957, MF6182, MF6216

**Bromus japonicus* Thunb., Japanese brome, 3; u; O,D,C. F16953, MF5958, MF6117, MF6215, MF6476

Buchloë dactyloides (Nutt.) Engelm., Buffalo grass, 4; m; O,D,C. F16933, MF6043, MF6164, MF6219

Cenchrus spinifex Cav., Coast sandbur, 4; s,u; O. [*C. incertus* M.A. Curtis – A, F] FM17649, MF5993

Chloris verticillata Nutt., Whorled windmill grass, 3; u; O,D,C. MF6166, MF6333, MF6480

Chloris virgata Sw., Showy windmill grass, 1; u; O,C. FM17845, FM18913

**Cynodon dactylon* (L.) Pers., Common Bermuda grass, 2; u; O,C. FM17882, MF5956

Dichanthelium oligosanthes (Schult.) Gould var. *scribnerianum* (Nash) Gould, Scribner's panicum, 3; w,s; O,C. MF5936, MF6035, MF6367, MF6484

**Digitaria ciliaris* (Retz.) Koeler, Southern crab grass, 1; u; O. [*D. adscendens* (Kunth) Henrard – A] FM17696

Digitaria cognata (Schult.) Pilg. subsp. *cognata*, Fall witch grass, 3; s,m; O. [*Leptoloma cognatum* (Schult.) Chase – A, F] FM17619, FM18285, MF6466

**Digitaria sanquinalis* (L.) Scop., Hairy crab grass, 2; u; O. FM17909, FM18342, MF5978

**Echinochloa crusgalli* (L.) P. Beauv., Common barnyard grass, 3; l,u; O,C. FM17612, FM17937, FM18376

Echinochloa muricata (P. Beauv.) Fernald var. *microstachya* Wiegand, Rough barnyard grass, 2; p,r,l; D,C. FM17794, FM18452, L2001 31

Echinochloa muricata (P. Beauv.) Fernald var. *muricata*, Rough barnyard grass, 3; p,r; O,D,C. FM17686, MF6156, MF6249, MF6394

Elymus canadensis L. var. *canadensis*, Canadian wild-rye, 3; w,s,m; O,D,C. MF5989, MF6151, MF6266, MF6432

Elymus virginicus L. var. *virginicus*, Virginia wild-rye, 2; w,m; O,C. FM17549, L2001-117, MF6377

**Eragrostis barrelieri* Daveau, Mediterranean love grass, 1; u; O,C. FM18381a, FM18468

**Eragrostis cilianensis* (All.) Vignolo ex Janch., Stink grass, 2; u; O,D. FM17563, FM17793, FM18334

Eragrostis curtipedicellata Buckley, Gummy love grass, 1; w; O. FM17682

**Eragrostis curvula* (Schrad.) Nees var. *conferta* Stapf, Weeping love grass, 3; s,m,u; O,D,C. FM17569, FM17787, MF5963, MF6393, MF6434, MF6455

Eragrostis pectinacea (Michx.) Nees var. *pectinacea*, Carolina love grass, 3; u; O. FM17602, FM18381b, MF5977

Eragrostis secundiflora C. Presl subsp. *oxylepis* (Torr.) S.D. Koch, Red love grass, 1; s; O. [*E. oxylepis* (Torr.) Torr. – A] FM17564

Eragrostis sessilispica Buckley, Tumble love grass, 2; s; O. MF6048, MF6467

Eragrostis spectabilis (Pursh) Steud., Purple love grass, 2; s,m; O,C. FM18286, FM18445

Eragrostis trichodes (Nutt.) A.W. Wood, Sand love grass, 2; s; O. FM18288

Eriochloa contracta Hitchc., Prairie cup grass, 1; l; D. FM17795

Erioneuron pilosum (Buckley) Nash var. *pilosum*, Hairy tridens, 4; s,m; O,D,C. [*Tridens pilosus* (Buckley) Hitchc. – A, F] MF6087, MF6221, MF6464

Hordeum jubatum L., Fox-tail barley, Squirrel-tail grass, 3; s,m,l; D. MF5968, MF6184

Hordeum pusillum Nutt., Little barley, 4; s,m; O,D,C. MF5992, MF6157, MF6218

Leersia oryzoides (L.) Sw., Rice cut grass, 3; p,r,l; O,C. FM17688, FM18351, FM18447

**Lolium perenne* L. var. *aristulatum* Willd., Perennial rye grass, 1; u; D. MF6180

Muhlenbergia asperifolia (Nees & Meyen ex Trin.) Parodi, Alkali muhly, Scratch grass, 3; r,l; O,D. FM17637, FM18347, FM18434

Muhlenbergia mexicana (L.) Trin., Mexican wire-stem muhly, 1; w; C. FM17818

Muhlenbergia racemosa (Michx.) Britton et al., Marsh muhly, 1; w,p,r; O. FM18344

Muhlenbergia sobolifera (Muhl. ex Willd) Trin., Rock muhly, 1; w; O. FM18345

Panicum capillare L. var. *barbipulvinatum* (Nash) McGregor, Common witch grass, 2; l; C. FM18438

Panicum capillare L. var. *brevifolium* Vasey ex Rydb. & Shear, Common witch grass, 2; w; O. FM17675, FM18296

Panicum dichotomiflorum Michx., Fall panicum, 2; l,u; O. FM17618

Panicum hillmanii Chase, Hillman's panicum, 2; s,r; O. FM17570

Panicum virgatum L., Switch grass, 2; m,r,l; O,D,C. FM17617, FM17782, FM17866, FM18287

Pascopyrum smithii (Rydb.) Á. Löve, Western pasture-wheat, Western wheat grass, 4; m,r,l; O,D,C. [*Agropyron smithii* Rydb. – A, F] MF6040, MF6159, MF6268, MF6396

Paspalum setaceum Michx. var. *stramineum* (Nash) D.J. Banks, Thin paspalum, 3; s; O. FM17643, MF5972, MF6479

Phalaris caroliniana Walter, Reed canary grass, 2; r,l,u; O,D. MF5961, MF6132

**Poa annua* L., Annual blue grass, 1; m,u; C. F16934

Poa arachnifera Torr., Texas blue grass, 1; s; O. MF6034

Poa arida Vasey, Plains blue grass, 4; w,m; O,D. F16870, F16885, F16903

**Polypogon monspeliensis* (L.) Desf., Annual rabbit's-foot grass, 2; p,r,l; O,C. MF5966, MF6243

Schedonnardus paniculatus (Nutt.) Trel., Tumble grass, 2; s,m; O,D,C. MF6165, MF6217, MF6465

Schizachyrium scoparium (Michx.) Nash subsp. *scoparium*, Little bluestem, 5; s,m; O,D,C. [*Andropogon scoparius* Michx. – A, F] FM 17531, FM17596, FM17785, FM17895, FM18400

**Secale cereale* L., Rye, 1; u; O. MF6012, MF6460

Setaria parviflora (Poir.) Kerguélen, Knot-root bristle grass, 4; p,r,l; O,D,C. [*S. geniculata* (Lam.) P. Beauv. – A, F] FM17583, FM17723, FM17744, FM17886

**Setaria viridis* (L.) P. Beauv., Green bristle grass, 3; u; O,C. FM17697, FM17911, MF5947, MF6376

Sorghastrum nutans (L.) Nash, Indian grass, 4; s,m,r; O,D,C. FM17786, FM18352, FM18460

**Sorghum halepense* (L.) Pers., Johnson grass, 3; u; O,D,C. FM17669, FM18326, MF6423, MF6450, MF6492

Sphenopholis obtusata (Michx.) Scribn. var. *obtusata*, Prairie wedgescale, 1; w; O. MF5962

Sporobolus clandestinus (Biehler) Hitchc., South-eastern dropseed, 2; s; O. [*S. asper* (P. Beauv.) Kunth var. *clandestinus* (Biehler) Shinners – A, F] FM18294

Sporobolus compositus (Poir.) Merr. var. *compositus*, Tall dropseed, 4; m; D. [*S. asper* (P. Beauv.) Kunth – A, F] FM18401

Sporobolus cryptandrus (Torr.) A. Gray, Sand dropseed, 4; s,m,u; O,D,C. FM17551, FM17915, L2001-40, MF6179, MF6334, MF6485

Sporobolus vaginiflorus (Torr. & A. Gray) A.W. Wood, Poverty dropseed, 3; u; O,C. FM18277, FM18367

Tridens albescens (Vasey) Wooton & Standl., White tridens, 3; w,m,l; D,C. FM17554, L2001-34, MF6160, MF6251

Tridens flavus (L.) Hitchc. var. *flavus*, Purpletop, 3; w,s,m,u; O,C. FM17677, FM18295, FM18451

Tridens muticus (Torr.) Nash var. *elongatus* (Buckley) Shinners, Slim tridens, 1; m; C. FM18450

Triplasis purpurea (Walter) Chapm. var. *purpurea*, Purple sand grass, 2; s; O. FM18292

Trisetum interruptum Buckley, Prairie trisetum, 3; s,m; D,C. MF6088, MF6214

**Triticum aestivum* L., Bread wheat, 1; u; D. MF6115

Vulpia octoflora (Walter) Rydb. var. *glauca* (Nutt) Fernald, Six-weeks annual-fescue, 4; m; O,D,C. [*Festuca octoflora* Walter – A, F] FL16834, FL16884, MF5960, MF6203, MF6475

POLEMONIACEAE

Ipomopsis longiflora (Torr.) V.E. Grant, Long-flower ipomopsis, 2; s,m; O,C. FM18368, Ts.n.

POLYGALACEAE

Polygala alba Nutt., White milkwort, 3; s,m; O,D,C. F16923, MF6067, MF6105, MF6204

Polygala verticillata L., Whorled milkwort, 2; s; O. FM17674, FM17707, MF6063

POLYGONACEAE

Eriogonum alatum Torr. var. *glabriusculum* Torr., Winged wild-buckwheat, 4; m; O,D,C. FM17544, FM17623, FM17757, FM17809, FM18390, FM18479, L2000-83, L2001-19, L2001-75

Eriogonum annuum Nutt., Annual wild-buck-wheat, 4; s,m; O,D,C. FM17575, FM17891, FM17922, FM18320, FM18388, L2001 88

Eriogonum longifolium Nutt. var. *longifolium*, Lance-leaf wild-buckwheat, 4; s,m; O,D,C. FM17545, FM17585, FM17756, FM17810, FM18389, FM18478, L2001-15, MF6286

**Polygonum arenastrum* Boreau, Sand knotweed, Doorweed, 3; u; O,C. MF5996, MF6237, MF6388

Polygonum lapathifolium L., Pale smartweed, Dock-leaf smartweed, 2; r,l; O,D,C. FM17749, FM18353, L2001-84, MF6248

Polygonum ramosissimum Michx., Bushy knot-weed, 2; w; O,D. FM17715, FM18354, L2001-21

Polygonum tenue Michx., Pleat-leaf knotweed, Slim knotweed, 2; s; O. FM17635, FM17699, FM18284

Rumex altissimus A.W. Wood, Pale dock, 2; l; C. MF6315

**Rumex crispus* L., Curly dock, 2; l,u; O,D,C. MF5942, MF6369

PORTULACACEAE

Portulaca oleracea L., Common purslane, 2; s,l,u; O,D,C. FM17577, F17799, FM17824

Talinum calycinum Engelm., Rock pink fameflower, 1; s; O. FM17737

POTAMOGETONACEAE

Potamogeton nodosus Poir., Long-leaf pondweed, 3; l; D,C. FM17854, FM18413

Stuckenia pectinata (L.) Börner, Sago pondweed, 2; l; O,D,C. [*Potamogeton pectinatus* L. – A, F] FM17844, FM18375, MF6329

PRIMULACEAE

Androsace occidentalis Pursh, Western rock-jasmine, 2; m; O,D. F16830, F16894

Samolus parviflorus Raf., Small water-pimpernel, 3; p,r,l; O,D,C. FM17724, FM17758, FM17857, FM18441, MF5967

RANUNCULACEAE

Anemone berlandieri Pritz., Ten-petal anemone, 3; m; O,D,C. F16872

Delphinium carolinianum Watler subsp. *virescens* (Nutt.) R.E. Brooks, Plains larkspur, 2; s,m; O,D,C. [*D. virescens* Nutt. – A; *D. virescens* Nutt. subsp. *penardii* (Huth) Ewan – F] MF6032, MF6145, MF6193

Ranunculus cymbalaria Pursh, Shore buttercup, 2; l; D,C. FM17880, FM18443

Ranunculus sceleratus L. var. *sceleratus*, Cursed crowfoot, Blister buttercup, 2; l; O,C. FM18442, MF5969, MF6282

RHAMNACEAE

Ceanothus herbaceus Raf., Inland ceanothus, 3; s,m; O,D,C. [*C. herbaceus* Raf. var. *pubescens* (Torr. & A. Gray ex S. Watson) Shinners – A, F] F16844, FM17520, FM17781, MF6001

ROSACEAE

Geum canadense Jacq., White avens, 2; w; O,C. MF5935, MF6365

Potentilla paradoxa Nutt., Bushy cinquefoil, 2; l; D,C. FM17742, FM18455

Prunus angustifolia Marshall, Chickasaw plum, Sandhill plum, 3; s,m; O,D,C. MF6060, MF6322, MF6323, MF6355, MF6459

Prunus gracilis Engelm. & A. Gray, Oklahoma plum, 2; s; O. F16883, FM17627, MF6429, MF6458

Rubus bushii L.H. Bailey, Bush's blackberry, 1; w; O. MF5964

RUBIACEAE

Cephalanthus occidentalis L., Common buttonbush, 3; m,r,l; D,C. FM17764, FM17867

Galium aparine L., Catch-weed bedstraw, 2; w,u; O,C. F16912, MF5939, MF6303

Galium circaezans Michx., Forest bedstraw, 3; w; O,C. FM17870, MF5938, MF6363

Hedyotis nigricans (Lam.) Fosberg var. *nigricans*, Narrow-leaf bluets, 3; s,m; O,D,C. FM17706, MF6019, MF6097, MF6246, MF6416

SALICACEAE

Populus deltoides W. Bartram ex Marshall subsp. *monilifera* (Aiton) Eckenw., Plains cottonwood, 5; w,m; O,D,C. F16905, FM18383, MF6319, MF6456

Salix exigua Nutt. subsp. *interior* (Rowlee) Cronquist, Sandbar willow, 2; w,r,l; O,D,C. F16906, FM17729, FM17766, FM18425

Salix nigra Marshall, Black willow, 2; w,r,l; O,C. F16889, MF6279

SANTALACEAE

Comandra umbellata (L.) Nutt. subsp. *pallida* (A. DC.) Piehl, Umbellate bastard toad-flax, 2; m; D,C. F16851, MF6295

SAPINDACEAE

Sapindus saponaria L. var. *drummondii* (Hook. & Arn.) L.D. Benson, Southern soapberry, 3; w,m; D,C. [*S. drummondii* Hook. & Arn. – A] FM17820, MF6325

SAPOTACEAE

Sideroxylon lanuginosum Michx. subsp. *oblongifolium* T.D. Penn., Woolly jungle plum, Chittimwood, 3; w,m; O,D,C. [*Bumelia lanuginosa* (Michx.) Pers. var. *oblongifolia* (Nutt.) R.B. Clark – A, F] FM17816, FM18338, FM18430, MF5995, MF6324

SCROPHULARIACEAE

Agalinis aspera (Douglas ex Benth.) Britton, Rough agalinis, 2; m; D,C. FM18387, L2001-10, L2001-73

Castilleja purpurea (Nutt.) G. Don var. *citrina* (Pennell) Shinners, Citron paintbrush, 3; m; O,D,C. F16860, F16942, MF6306, MF6497

Castilleja sessiliflora Pursh, Downy paintbrush, 3; m; D. F16846

Nuttallanthus texanus (Scheele) D.A. Sutton, Texas toad-flax, 3; s; O. [*Linaria canadensis* (L.) Dumort. var. *texana* (Scheele) Pennell – A, F] F16888

Penstemon albidus Nutt., White beardtongue, 4; m; D,C. F16900, MF6253, MF6341

Penstemon buckleyi Pennell, Buckley's beard-tongue, 2; s; O. F16877, MF6452

Penstemon cobaea Nutt. var. *cobaea*, Cobaea beardtongue, 3; m; D,C. FM17523, L2001-93, MF6101, MF6190, MF6401

Penstemon fendleri Torr. & A. Gray, Fendler's beard-tongue, 2; m; D. F16823, MF6342

**Veronica catenata* Pennell, Blue water speed-well, 2; p,r; O. MF5965

Veronica peregrina L. subsp. *xalapensis* (Kunth) H. St. John & F.A. Warren, Purslane speedwell, 2; w,m,l; D. F16842, MF6356

SMILACACEAE

Smilax hispida Muhl. ex Torr., Bristly greenbrier, 1; w; C. MF6382

SOLANACEAE

Chamaesaracha coniodes (Moric. ex Dunal) Britton, Dusty false-nightshade, 2; m; D,C. F16867, MF6169, MF6264

Datura inoxia Mill., Hairy thorn-apple, 1; w,u; O. [*D. meteloides* DC. – A; *D. wrightii* Regel – A] FM18331

Physalis cinerascens (Dunal) Hitchc. var. *cinerascens*, Ashy ground-cherry, 3; w,s,m; O,D,C. [*P. viscosa* L. subsp. *mollis* (Nutt.) Waterf. var. *cinerascens* (Dunal) Waterf. – F; *P. viscosa* L. var. *cinerascens* (Dunal) Waterf. – A] FM17684, MF6109, MF6174, MF6240, MF6496

Physalis longifolia Nutt. var. *longifolia*, Long-leaf ground-cherry, 3; s,m; O,C. MF6425, MF6426, MF6495

Quincula lobata (Torr.) Raf., Purple ground-cherry, 3; m,u; D,C. F16852, MF6175, MF6241

Solanum dimidiatum Raf., Western horse-nettle, 3; s,m; O,D,C. FM17710, FM18900, FM17927, FM18429, MF6057

Solanum elaeagnifolium Cav., Silver-leaf night-shade, 3; s,m; O,D,C. FM17829, MF5984, MF6126, MF6227, MF6493

Solanum interius Rydb., Plains black nightshade, 1; u; C. FM18469

Solanum rostratum Dunal, Buffalo bur night-shade, 2; s,m,l,u; O,D,C. FM17620, MF6155, MF6226

TAMARICACEAE

**Tamarix ramosissima* Ledeb., Salt-cedar, 2; p,r,l; O,D,C. FM17760, MF5983, MF6321

TYPHACEAE

Typha domingensis Pers., Southern cat-tail, 4; p,l; O,C. FM17622, FM17687, FM17878, FM18378

ULMACEAE

Celtis laevigata Willd., Sugar hackberry, Sugar-berry, 1; w; C. MF6381

Celtis reticulata Torr., Net-leaf hackberry, 4; w,m; O,D,C. F16882, FM18358, MF5954, MF6141, MF6326

Ulmus americana L., American elm, 4; w; O,D,C. F16871, MF5952, MF6142, MF6320

URTICACEAE

Parietaria pensylvanica Muhl. ex Willd., Pennsyl-vania pellitory, 2; w,m; O,C. F16895, MF6281, MF6371

VERBENACEAE

Glandularia bipinnatifida (Nutt.) Nutt. var. *bipinnatifida*, Dakota vervain, 3; m; D,C. [*Verbena bipinnatifida* Nutt. – A, F] F16920, MF6147, MF6270

Phyla lanceolata (Michx.) Greene, Northern fogfruit, Lance-leaf fogfruit, 2; p,l; O,C. [*Lippia lanceolata* Michx. – F] FM17722, FM17887

Phyla nodiflora (L.) Greene, Turkey-tangle, Com-mon fogfruit, 3; l; D,C. [*Lippia nodiflora* (L.) Michx. var. *nodiflora* – F; *P. incisa* Small – A] FM17745, FM17828, FM17862, FM18453, MF6150, MF6309

Verbena bracteata Lag. & Rodr., Prostrate vervain, 2; u; O,D,C. L2001 24, MF5980, MF6271

Verbena hastata L., Blue vervain, 1; p,r; O. FM17720

Verbena stricta Vent., Hoary vervain, 2; s,m,u; O,C. FM17605, FM17885

Verbena urticifolia L., Nettle-leaf vervain, 2; w; O. FM17676

VIOLACEAE

Viola bicolor Pursh, Johnny-jump-up, 3; w,u; O,C. [*V. rafinesquii* Greene – A, F] F16907, MF6078

Viola pratincola Greene, Meadow violet, 1; w,r; O. F16893

VITACEAE

Ampelopsis cordata Michx., Heart-leaf raccoon-

grape, 3; w; O,C. FM17690, FM17730, FM17783, FM17871, MF5944, MF6391

Parthenocissus quinquefolia (L.) Planch., Virginia creeper, 3; w; O,D,C. FM17673, FM17770, MF5946, MF6328, MF6387

Parthenocissus vitacea (Knerr) Hitchc., Thicket creeper, Woodbind, 2; w; D. FM18427

Vitis acerifolia Raf., Bush grape, 3; w,s,m; O,D,C. FM17864, FM18426, MF6059, MF6158, MF6276

ZYGOPHYLLACEAE

**Tribulus terrestris* L., Spreading puncturevine, Goat's head, 1; u; D. FM17943

ACKNOWLDEGMENTS

The Dempsey Divide Research Foundation, Inc., the R. L. McGregor Herbarium, and the Kansas Biological Survey provided financial support for this study. We thank Hillary Loring and Kelly Kindscher for their assistance in the field and for their review of the draft manuscript. Ronald McGregor, Bruce Hoagland, and Adam Ryburn also reviewed the manuscript and offered numerous helpful suggestions. Jennifer Delisle kindly prepared the map.

BOOK NOTICES

W.T. Parsons and E.G. Cuthbertson. 2001. **Noxious Weeds of Australia, Second Edition.** (ISBN 0643065148, hbk.). CSIRO Publishing, PO Box 1139, Collingwood Vic 3066, AUSTRALIA. (Orders: Antipodes Books & Beyond Ltd (USA & Canada), 9707 Fairway Ave., Silver Spring, MD 20901-3001, U.S.A., 301-602-9519, fax 301-565-0160, email: antipode@antipodesbooks.com, www.antipodesbooks.com or CSIRO Publishing, publishing.sales@csiro.au, www.publish.csiro.au). AU$195.00, 712 pp., color throughout, maps, 7 1/4" × 10 1/4".

The first edition of *Noxious Weeds of Australia* was published in 1992. From the back cover: "Since the first edition of *Noxious Weeds of Australia*, numerous changes have taken place throughout Australia to the legal requirements for the control of proclaimed weeds and the manner in which they are classified. In this second edition, the authors have completely updated this information for each State and Territory and have listed the newly proclaimed weeds in an addendum. The list of herbicides and their properties has also been revised."

The intended audience according to the authors is "farmers, agricultural advisers, environmentalists, ecologists, representatives of agricultural chemical companies, stock and station agents, herbicide applicators, administrators, students of agriculture and anyone else with an interest." But with information on over 200 species including nomenclature, habitat, description, and distribution maps, and the occasional line drawing, the book will also be useful to the botanist and taxonomists. Many of the weeds covered in this book are widespread making the book useful beyond Australia.—*Barney Lipscomb, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX 76102-4060, U.S.A., barney@brit.org.*

Lena Struwe and Victor A. Albert (Editors). 2002. **Gentianaceae: Systematics and Natural History.** (ISBN 0-521-80999-1, hbk.). Cambridge University Press, The Edinburgh Bldg., Cambridge CB2 2RU, U.K. (Orders: 40 West 20th ST., New York, NY 10011-4211, U.S.A. www.cup.org, www.cup.cam.ac.uk). $130.00, 652 pp., b/w photos, line drawings, graphs, 6" × 9".

This volume is a comprehensive review of the Gentianceae family including the latest information on phylogeny, classification, biogeography, palynology, phytochemistry, and morphology. "Descriptions of each of the 87 gentian genera are provided, as are discussions on morphological evolution and biogeography for each major evolutionary lineage."

Contents: **1)** Gentianaceae in context (V.A. Albert and L. Struwe); **2)** Systematics, character evolution, and biogeography of Gentianaceae, including a new tribal and subtribal classification (L. Struwe, J.W. Kadereit, J. Klackenberg, S. Nilsson, M. Thiv, K.V. von Hagen, and V.A. Albert); **3)** Cladistics of Gentianaceae: a morphological approach (S. Mészáros, J. De Laet, V. Goethals, E. Smets, and S. Nilsson; **4)** Gentianaceae: a review of palynology (S. Nilsson); **5)** The seeds of Gentianaceae (F. Bouman, L. Cobb, N. Devente, V. Goethals, P.J.M. Maas, and E. Smets); **6)** Chemotaxonomy and pharmacology of Gentianaceae (S.R. Jensen and J. Schripsema); and Index.

WEST GULF COASTAL PLAIN ECOREGIONS

ABSTRACT

We review the literature on West Gulf Coastal Plain ecoregions and examine the methodology used by ecoregion mappers. Ecoregion mapping has been done almost entirely without quantitative assessment. We suggest that quantitative descriptions should replace impressionistic descriptions.

KEY WORDS: West Gulf Coastal Plain, Ecoregions

RESUMEN

Hemos revisado la bibliografía de las ecorregiones de la West Gulf Coastal Plain y examinado la metodología usada por los cartógrafos de ecorregiones. La cartografía ecorregional ha sido realizada casi totalmente sin evaluación cuantitativa. Sugerimos que las descripciones cuantitativas deben reemplazar a las descripciones impresionistas.

INTRODUCTION

Half a century ago, Webb (1950) examined the methodology of biogeographers who had mapped Texas and Oklahoma ecoregions. He found not only that ecoregional mappers did not agree among themselves but that ecoregional mapping was subjective. He suggested a remedy: "quantitative methods must be developed before general agreement on the extent of the major [ecoregions] can be reached. As long as personal opinion and individual judgment are the only basis for judging the extent of the [ecoregions], fundamental and insoluble differences of opinion will continue" (Webb 1950:246). Using vertebrates, he quantitatively assessed the ecoregions of Texas and Oklahoma. His ecoregions did not correspond with those developed by botanists and botanically oriented ecologists. A decade and a half later, Gleason and Cronquist (1964:177), referring to the entire North American continent, reiterated Webb's point in almost the same words but made no quantitative analysis. More recently, Hargrove and Luxmoore (1998), again looking at the entirety of North America, recognized the same thing: "Because the delineation [of ecoregions] is based on subjective criteria, there are as many sets of ecoregions as there are experts."

These assertions prompted us to examine the history of floristic ecoregion delineation in the West Gulf Coastal Plain (WGCP). We will be concerned

mainly with three ecoregions: Longleaf Pine (LLP), Post Oak Savanna (POSa), and Oak-Pine-Hickory (OPH). One of the traditional designations and locations of these WGCP ecoregions is given in Figure 1.

There are numerous descriptions of each of these ecoregions (e.g., Tharp 1939; Gould 1962; Correll & Johnston 1970; LBJ School of Public Affairs 1978; Hatch et al. 1990; Telfair 1999). The lack of pines, the codominance of oaks and hickories, and the ubiquitous presence of *Quercus stellata* Wang. are always emphasized when the POSa region is described, the combination of pines, oaks, and hickories is emphasized in the description of the OPH ecoregion, and the LLP ecoregion is defined as being coterminous with the distribution of *Pinus palustris* Mill.

METHODS

1. Ecoregional mappers.—We surveyed the ecoregional literature dealing with the eastern part of the WGCP to see if Webb (1950), Gleason and Cronquist (1964), and Hargrove and Luxmoore (1998) were correct in their assessment of ecoregional mapping. The literature dealing directly or indirectly with the ecoregions of this area is extensive (Cooper 1859; Transeau 1903; Harshberger 1911; Shreve 1917; Shantz & Zon 1924; Tharp 1926, 1939, 1952; Carter 1931; Fenneman 1938; Dice 1943, 1968; Blair 1950; Braun 1950; Turner 1959; Gould 1962; Gleason & Cronquist 1964; Kuchler 1964; Kuchler & McCormick 1965; LBJ School of Public Relations 1978; Bailey 1980; McMahan et al. 1984; Omernik 1986; Takhtajan 1986; Diamond et al. 1987; De Graaf et al 1988; Diamond & Smeins 1988; Greller 1988; Barbour & Christensen 1993; Thorne 1993; Bailey et al. 1994; McNab & Avers 1994; Keys et al. 1995; Weakley et al. 1998; Diggs et al. 1999; Ricketts et al. 1999a, 1999b; Delcourt & Delcourt 2000). Mappers are discussed and their maps reproduced in the Appendix.

2. Floristics.—We made a number of quantitative ecoregional comparisons to see how similar or different these regions are. Since there is no complete floristic survey of any of the WGCP ecoregions, we had to rely on floristic lists from each (e.g., Anon. n.d.; McBryde 1933; Matos & Rudolph 1985; Nixon 1985; Bridges & Orzell 1989; Hatch et al. 1990; Orzell 1990; Louisiana Natural Heritage Program 1998; Turner et al. 1999; Van Kley 1999a, 1999b; MacRoberts & MacRoberts 2001), which we have compared with distributional data given in various floras, atlases, and plant lists (e.g., Smith 1988; MacRoberts 1989; Taylor & Taylor 1989; Hatch et al. 1990; Thomas & Allen 1993-1998; Kartesz & Meacham 1999; Turner 2003) and community classifications (Diamond et al. 1987; Louisiana Natural Heritage Program 1998; Bezanson 2000). To establish the existence of different floristic ecoregions one would expect there to be 1) significant regional floristic differences between ecoregions, 2) significant regional community differences between ecoregions, and 3) higher similarity within different parts of an ecoregion than between ecoregions. We were unable to compare species abundances between regions since the data are not available.

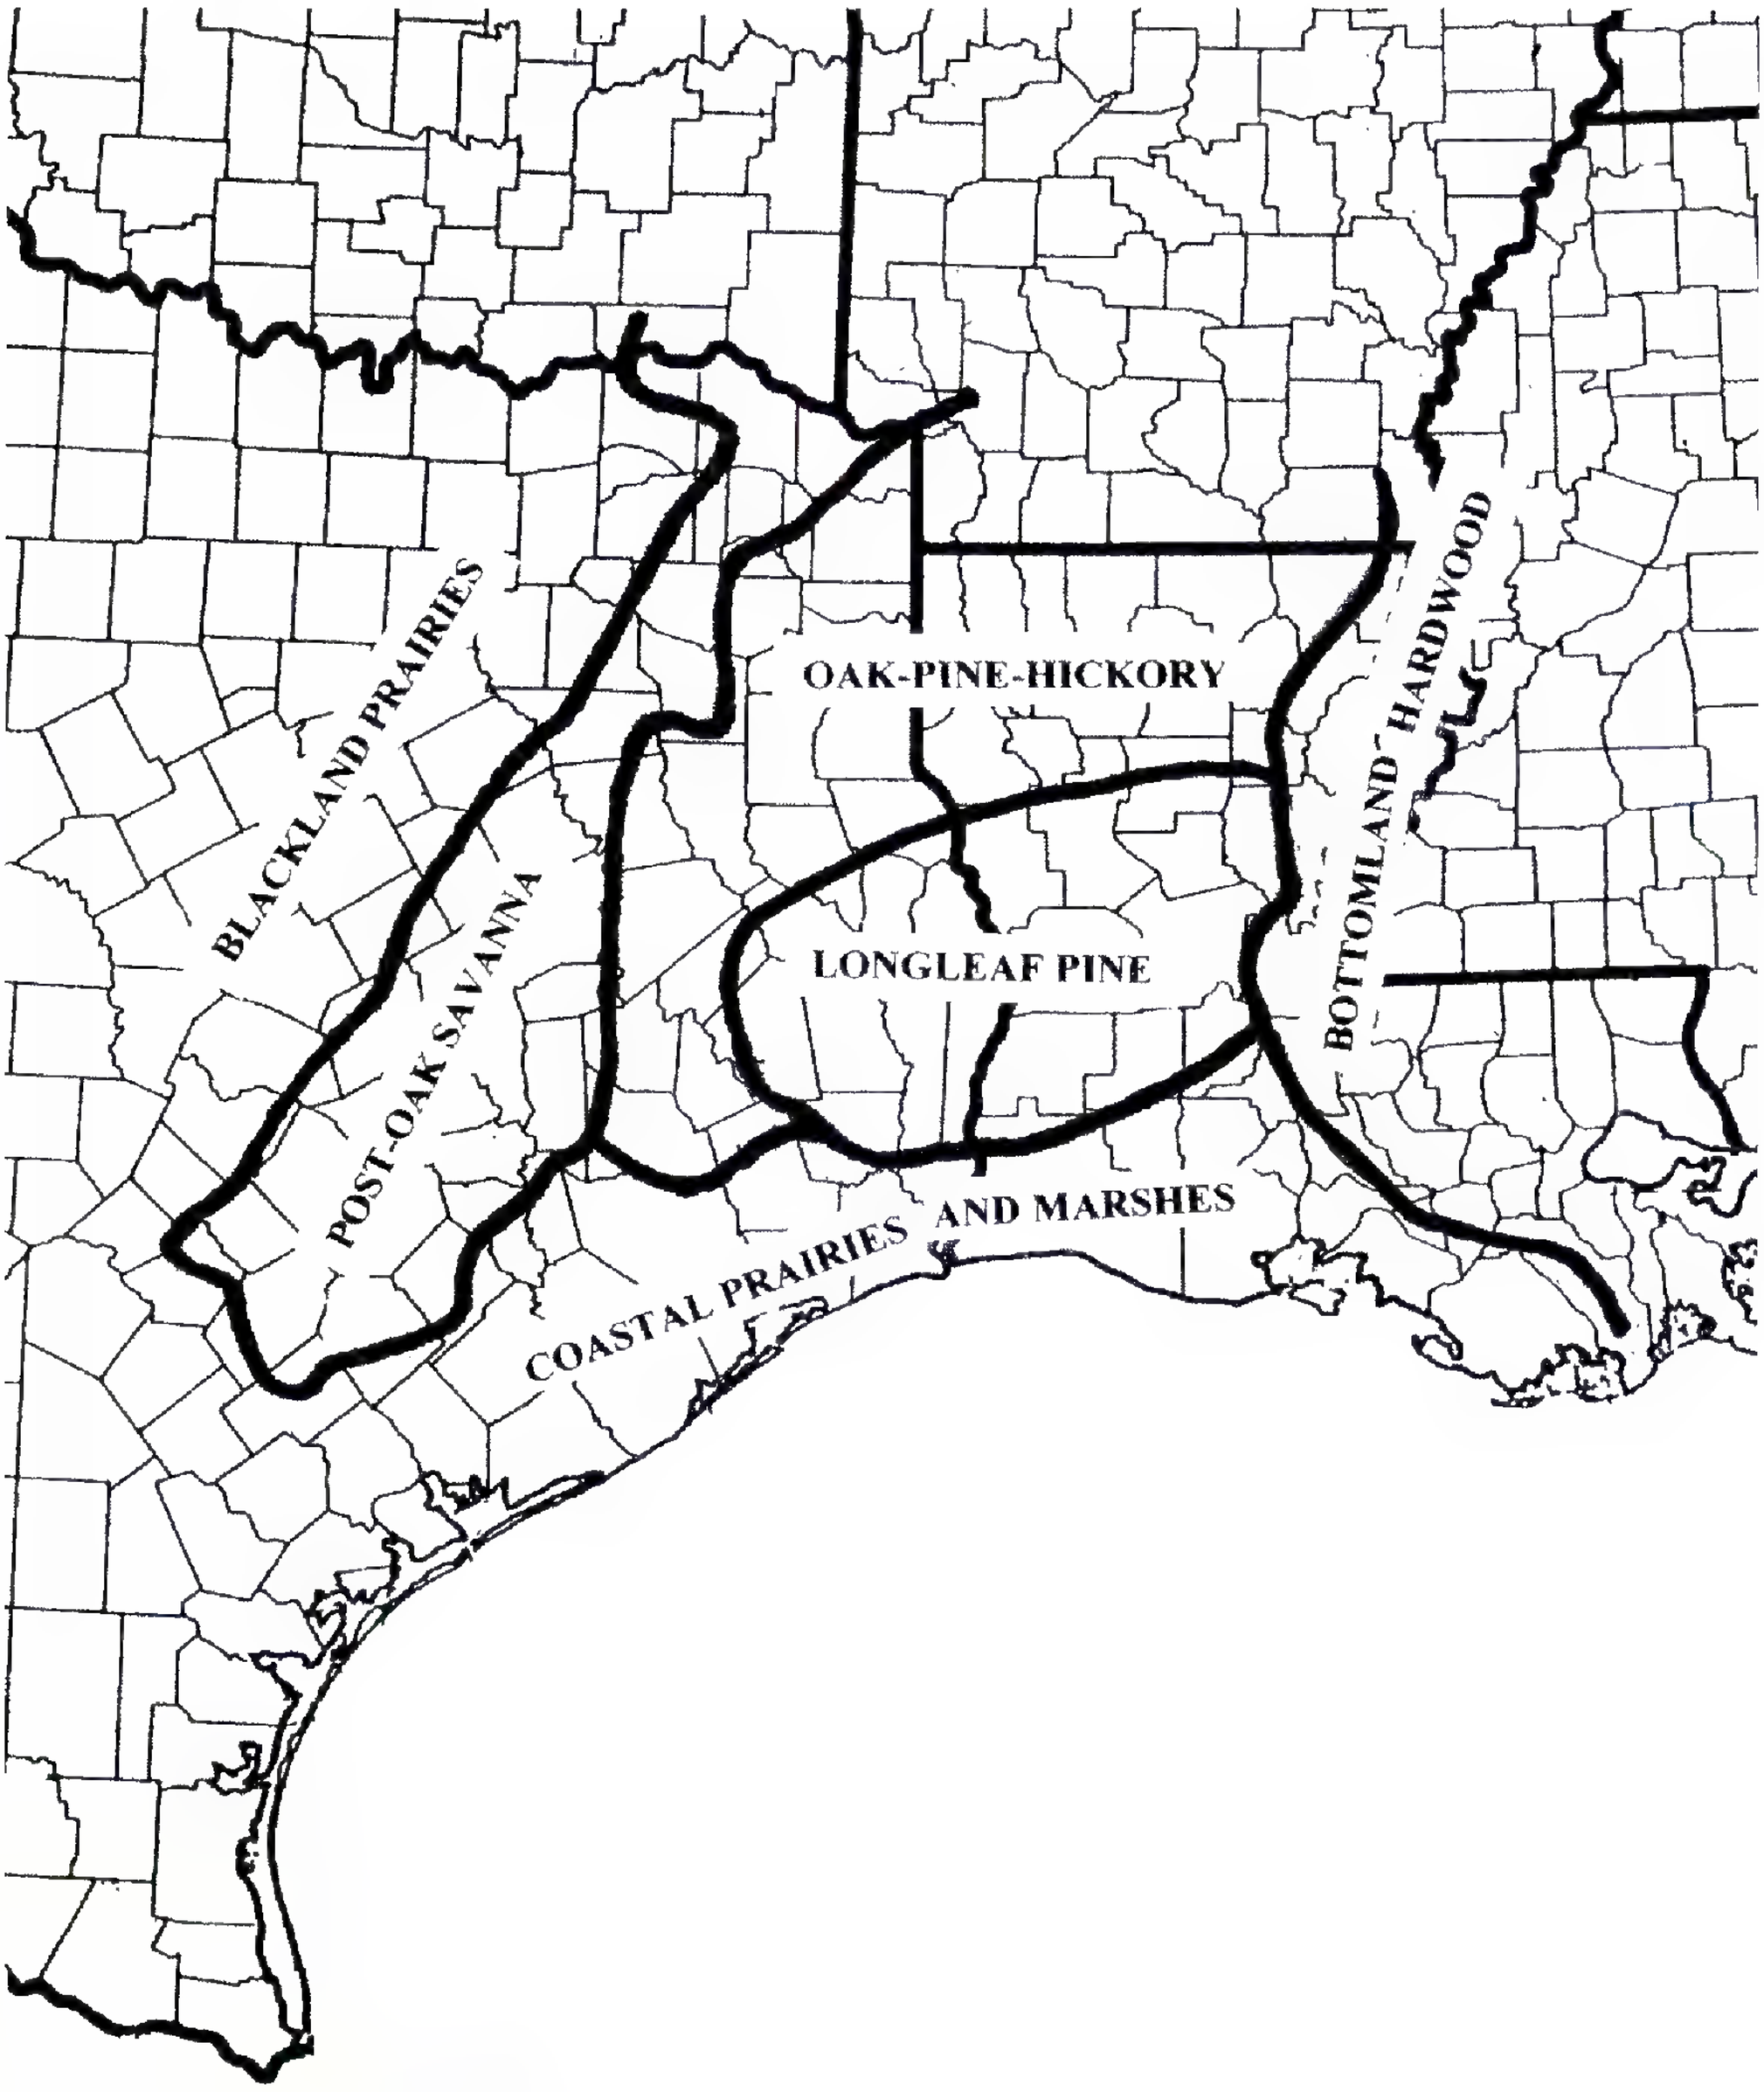

FIG. 1. Standard location of West Gulf Coastal Plains vegetation areas (ecoregions).

3. Soils.—The interrelationship of soils and flora has long fascinated ecologists (Warner 1926). Eastern versus western United States is clearly marked by a soil break (Carter 1931), and in the WGCP many plant communities are correlated directly with soils—e.g., blackland prairies, Weches Formation, and sandstone glades and outcrops. We surveyed the WGCP soil literature (Carter 1931; Godfrey et al. 1973; Steila 1993) to see if soils correlate with floristic ecoregional delineations.

4. Vertebrates.—Although our main focus is on the flora, we examined the literature on ecoregional distribution of vertebrates (except fish) in the WGCP in an attempt to see if animal distributions correlate with traditional plant ecoregions (Blair 1950; Webb 1950; McCarley 1959; Neck 1986; Gehlbach 1991; Wilkins 1992; Ward et al. 1994). Also, using lists of birds, reptiles, amphibians, and mammals from the WGCP, we plotted vertebrate distribution to see if there were any correlations with ecoregion.

RESULTS

1. Ecoregional mappers.—We confirmed the assessment of Webb (1950), Gleason and Cronquist (1964), and Hargrove and Luxmoore (1998). There have been dozens of WGCP ecoregional mappers, but, with one exception, there has been no floristic mapping based on quantitative data. Instead, we found that ecoregional mappers almost invariably base their maps on the presence or absence of one or a few "diagnostic" trees or a "suite" of trees, with little or no attention paid to herbaceous and understory species. None of the modern armament of statistical ecology and sampling (e.g., Mueller-Dombois & Ellenberg 1974; Peet et al. 1998) has been applied although it is beginning to be used in WGCP community ecology (Dale 1986; Turner et al. 1999). We also found little agreement among mappers.

Only Turner (1959) used quantitative methods and, not surprisingly, his results are unique (Fig. 2). Turner's method was relatively simple: he calculated "the percentage of species restricted to a given region ('endemic' species) and the percentage of species shared with other provinces ('shared' species). The percentage of restriction, expressed as that fraction of the total species known to occur in the province under consideration, was taken as the naturalness of the floral region" (Turner 1959:5 [see also Webb 1950 for comparable method using vertebrates]). He discovered that there were basically five regions in Texas that fit his criterion of 40% or higher for "endemism." Interestingly, he also found that attempts to delineate clearly distinct, but smaller, subdivisions resulted in such heterogeneous figures that these regions, on a floristic basis, would not be strictly comparable. Turner found that floristically the POSa, LLP, OPH, and Cross Timbers are similar and, therefore, he lumped them (his Appalachian) and separated from them the Prairie (his Campestrian) and South Texas Plains (his Tamaulipan) because they are different. This is a singular result among biogeographers, who invariably divide the WGCP into many ecoregions.

2. Floristics.—Using floristic and plant community lists from various areas within the POSa, OPH, and LLP regions, we compared floristic and community similarities and differences throughout the LLP, POSa, and OPH region of the WGCP. The result: all regions had greater than 90% of their flora in common. Virtually the same holds for communities. For example, pockets of prairie occur throughout the OPH, POSa, and LLP regions, bogs occur in all three

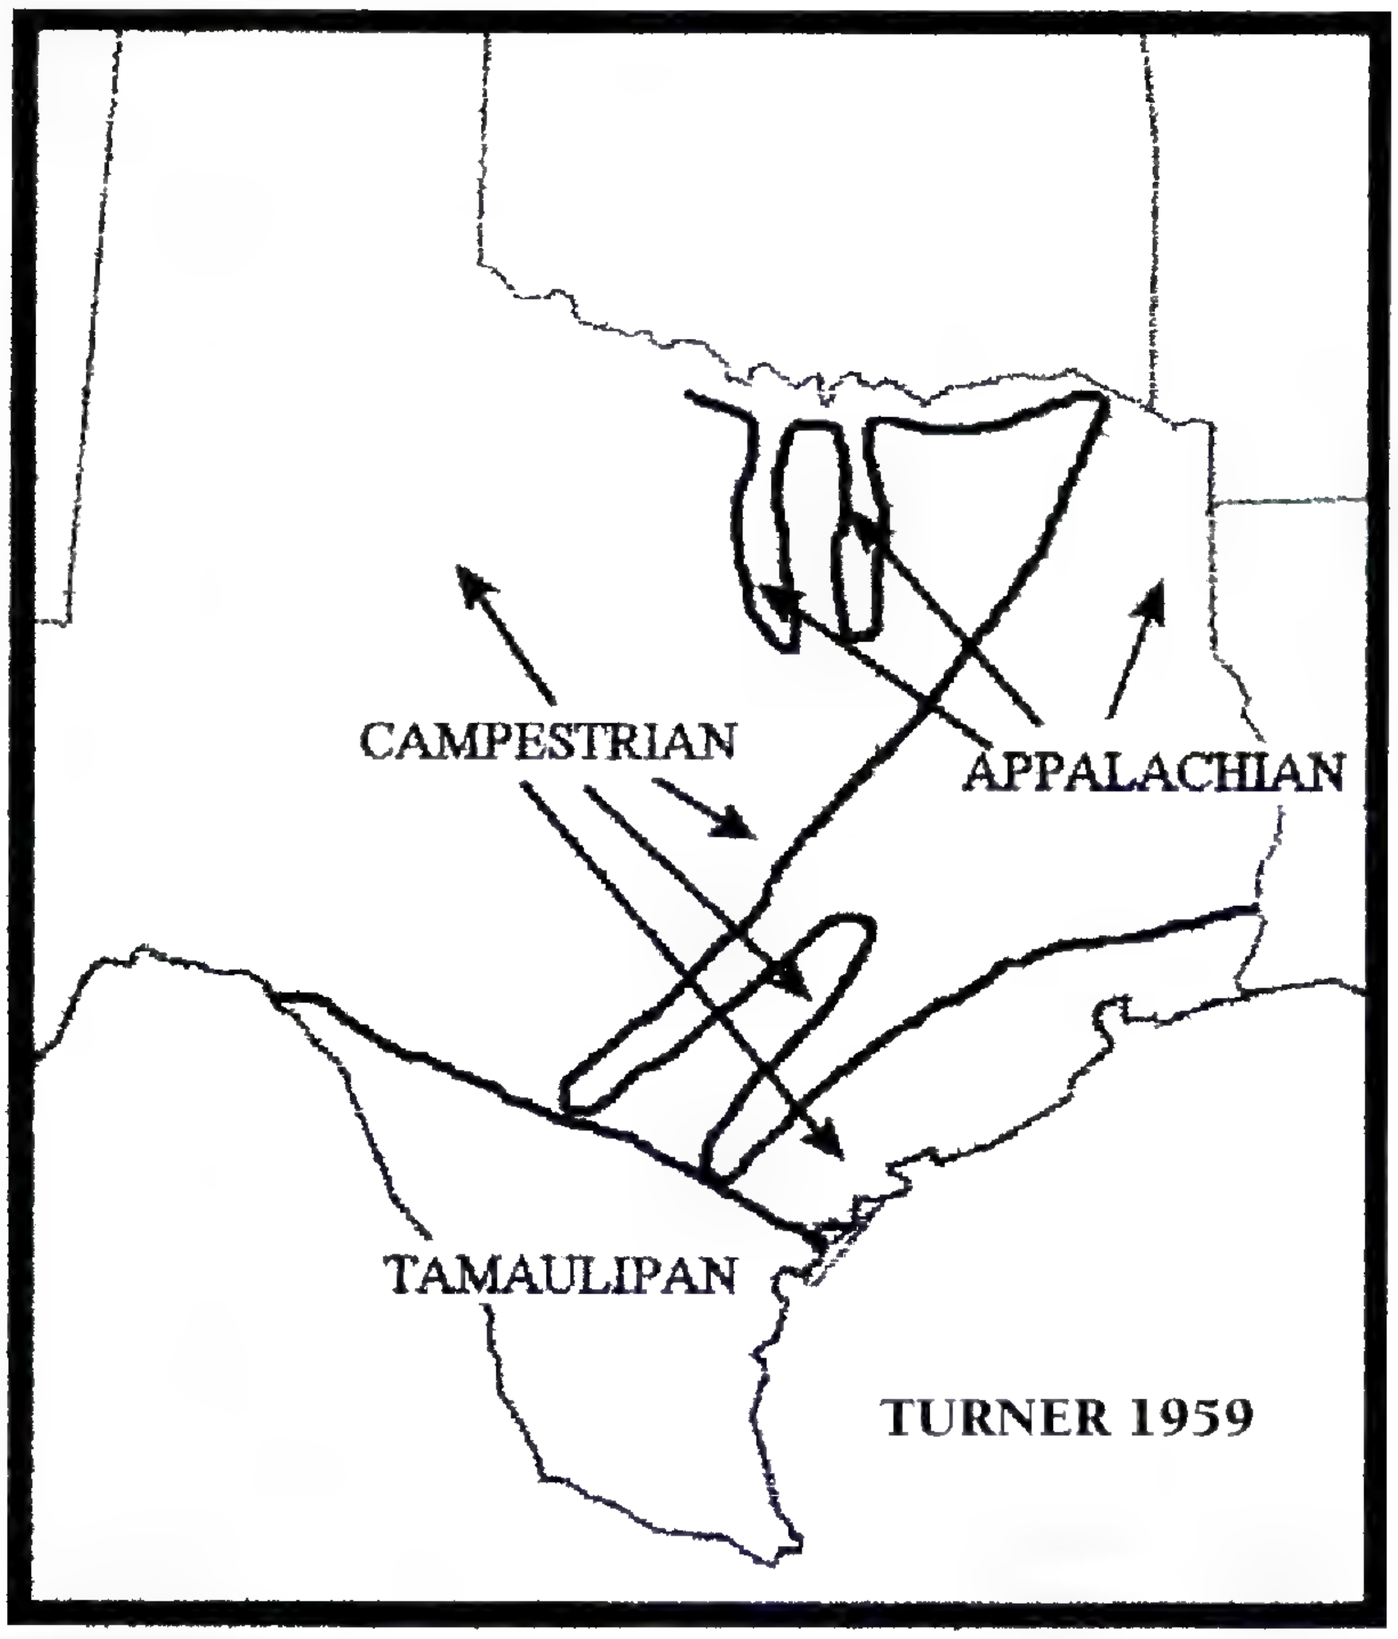

Fig. 2. B.L. Turner's (1959) Texas vegetation areas.

regions, notably in the LLP and POSa areas, hardwood-beech slopes are found in both LLP and OPH regions, baygalls are common in all three regions, grossarenic xeric sandylands and xeric oak woodlands are especially common in the POSa region but present in the other two regions as well, sandstone outcrops or barrens occur in the POSa and LLP regions, and so on. Since no one has collected the data to perform an analysis of species abundance, very little can be said about that parameter.

One of the predictions of biogeography (we assume) would be that different sections of the same ecoregion should be floristically more similar to each other than to different ecoregions. Biogeographers such as Kuchler (1964; see also Gleason & Cronquist 1964; Cronquist 1982; Takhtajan 1986) have placed states as distant as Maine, Michigan, and Texas in the same ecoregion or province (Oak-Hickory Forest, Appalachian Province). We compared the floristics between Kuchler's Oak-Hickory Forest in Texas (POSa ecoregion) and Oak-Hickory Forest in Missouri 300 miles away and the Oak-Hickory-Pine Forest (OPH ecoregion) in Mississippi 300 miles away. We found that the different ecoregions were more similar (Texas POSa and Mississippi OPH: 81% of species

in common) than areas within the "same" ecoregion (Texas POSa and Missouri POSa: 67% of species in common). We also compared the differences between Michigan and North Carolina and the POSa of east central Texas. Michigan and North Carolina are both 1000 miles from east central Texas, but Michigan is supposedly in the same province or ecoregion, while North Carolina is not. The result: Michigan had 44% and North Carolina had 75% of the species in common with Texas.

3. Soils.—A survey of the soil literature uncovered no overall soil/floristic correlations for the LLP, OPH, or the POSa ecoregions but instead a great interdigitation of soil types (largely Alfisols and Ultisols) throughout the region (Tharp 1952; Godfrey et al. 1973; Smeins & Diamond 1986). However, the prairie soils (both blackland and coastal) do fall out clearly along traditional floristic boundaries. On a broader note, Hargrove and Luxmoore (1998), using multivariate analysis of nine edaphic variables (including: elevation, soil, water, temperature, climate), produced a high resolution map of the United States. Overlaying this on traditional WGCP vegetation maps shows no correlations. The LLP, POSa, and OPH regions do not stand out individually but merge together into one general area.

4. Vertebrates.—Zoologists have long known that no correlation exists between vertebrates and the traditional floristic ecoregions. Instead, the prairie areas form a break between eastern and western species. Central Texas is a transition zone for vertebrates, but central Texas begins west of the POSa region (Webb 1950; Neck 1986; Gehlbach 1991; Wilkins 1992; Ward 1994). As far as vertebrates are concerned, the eastern WGCP as a whole is significant, not its components. Our survey of vertebrate distribution confirms the zoologists' contentions.

DISCUSSION

The most obvious finding of this study is that only one WGCP floristic ecoregion map was developed using quantitative methods and, parenthetically, it was subsequently ignored. All other schemes are subjective, the criticism made by Webb (1950), Gleason and Cronquist (1964), and Hargrove and Luxmoore (1998). There are no methodological descriptions, no quantitative data, no demarcation criteria, and no statistical analyses. Apparently, ecoregions are self-evident and impressionistic description is considered sufficient. The question Webb (1950:426) asked five decades ago is as pertinent today as it was then: "How different must the fauna and flora of two areas be before they are recognized as examples of different ecoregions?"

Only Turner (1959) attempted an answer, and he found that the eastern WGCP constituted a single floristic region. We have confirmed this finding: between 90% and 99% of species occurring in the LLP, OPH, and POSa regions also occur in the others, and the majority of plant communities are common to all three regions. When traveling from one region to another, the botanist does

not encounter a new flora, the zoologist a new fauna, and the ecologist a new set of plant and animal communities. What differences exist are not of kind but of degree. Sharp boundaries simply do not exist.

Many individuals have noted an east-west gradient between OPH and POSa regions. Tharp (1926:48) pointed out that *Quercus stellata* and *Q. marilandica* Muenchh. are often codominants with pine in the OPH ecoregion and that the transition to POSa "... merely means the gradual decrease of pine until it has disappeared." McCarley (1959:390) said: "The boundary between the pine-oak region and the oak-hickory region is nowhere sharply marked, but is characterized by a gradual decrease in pine and an increase in oaks and hickories." Wilson (1990:184) said: "At the western edge of the piney woods, the mixed pine-oak forest gave way to ... a hardwood forest similar in composition to the deciduous component of the mixed forest," and further, the pines disappear "from the forest leaving a mixed hardwood forest." Currie (1991), Nesom and Brown (1998) and Nesom et al. (1997) documented the loss of tree species diversity, not just pine, in the WGCP as one moves west. Although pockets of pines occur in the POSa region almost to Austin and Paris, Texas (Warner 1926; Wilson 1989), pines tend to drop out of the flora just before the true prairies are reached. Blair (1950) clearly had trouble separating the OPH and LLP regions from the POSa and spoke of an ecotone between them and the prairies farther west. Recent analysis of the distribution of *Pinus palustris* in east Texas does not support the simple story of savannas dominated by single species but rather tells a complex story involving the occurrence of mixed longleaf-shortleaf pine savannas not only on the periphery of the *Pinus palustris* range, but at its center (Evans 1997). Monk et al. (1990:77), in their study of so-called oak-hickory communities across the eastern United States, found that hickory was seldom, if ever, a dominant or codominant: "No real evidence was found for a regional oak-hickory forest." Dale and Ware (1999), commenting on this matter, pointed out that in contrast to these earlier findings, hickory may be a codominant in certain areas west of the Mississippi River.

Few question how the lines get on ecoregional maps—why a given line forms a polygon without internal polygons of other types. What is evident is that ecoregion delineations leave out all the messy detail; they are idealizations that actually describe very little of the area encircled. For example, at the macro-level the Takhtajan (1986) and Cronquist and Gleason (1964) descriptions of the Texas POSa region (their Appalachian and Eastern Deciduous Forest provinces) are so far out of the range of the "type" that they are simply not the same association of plants. At the micro-level, adjacent areas designated as different are not floristically different at all. As far as we have been able to ascertain, the LLP "ecoregion" is simply an autecological statement about the presettlement distribution of *Pinus palustris*. There is no unique LLP "ecoregion" flora with a substantial number of endemics and unique plant communities. The POSa

"ecoregion" is the western edge of the southeastern pine/oak forest and, as such, many species drop out; notably pines. But again there is no floristic break or large number of endemics or unique communities by which the POSa "ecoregion" can be described. The OPH "ecoregion" is similarly undifferentiated—aside from the absence of *Pinus palustris*, it is difficult to find anything that warrants setting it off as a separate region.

While the construction of ecoregional maps might seem to have little or no import, this is not entirely so. Ecoregions are the basis for deciding conservation priorities. For example, Diamond et al. (1997), Ricketts et al. (1999a, 1999b), Weakley et al. (1999), and Myers et al. (2000) all are concerned with priorities for conservation of rare species, endemic species, and rare habitat, and decisions about them are based on the concentration of rare species, endemics, and so on, which in turn is based on which map is selected: Ricketts et al. (1999a, 1999b) chose Omernick (1986), Weakley et al. (1998) chose Bailey et al. (1994), and Diamond et al. (1997) chose Gould (1962). Setting aside the almost insurmountable problems of how species numbers and their rareness are calculated for these ecoregions, the fact remains that size of area and its location make a lot of difference in deciding whether or not an ecoregion is an ecological "hot spot" or "cold spot." For example, Ricketts et al. (1999a) concluded that the OPH plus LLP ecoregions (their "Piney Woods Forests") had only 7 endemic plants and the POSa region (their "East Central Texas Forests") also had only 7 endemic plants. However, by combining the POSa, OPH, and LLP regions, we calculate that these three "regions" together have approximately 100 endemic or near-endemic plants, not 14!—thereby instantly changing the WGCP from an ecological cold spot to an ecological hot spot. A map that combines the POSa, LLP, and OPH regions makes for very different biogeography and conservation than one that divides them, and the decisions made by conservationists on the basis of one map may be very different from decisions made using another map.

We are not suggesting that the WGCP or that part of it we have examined in this paper is uniform. Quite the contrary. Previous biologists related something they were familiar with and observed, and we, like our predecessors, can see what was being referred to. If we are attentive, we can tell when we have entered the LLP region by the presence of *Pinus palustris*, and traveling west, we also note when pine vanishes and the landscape is dominated by oaks. We can see these changes because we have been conditioned to look for them and because they are there. We also have no doubt that in these different regions there are differences in species abundance. Thus, the absence of pines from the POSa region and the presence of pines in the OPH and LLP regions signals difference in canopy structure. But lacking in any of these ecoregional descriptions is hard data (floristic lists and abundance data) and statistical procedures and operations for determining when two samples are ecoregionally the "same" or "different." Instead, cultural idealizations and stereotypy substitute for concrete description and

analysis. Consequently, even if we wished to provide a brief summary description of any region inorder to recognize its most valuable or "true" features based on previous delineations would be to rely on idealized and stereotyped descriptions, and would be confounded by precisely what we are describing here.

It is premature to make any definitive statement on the WGCP ecoregions. However, on the basis of our experience and limited floristic sampling, we would say that there is certainly no reason to separate the LLP region from the OPH region. There is nothing revolutionary in this since about half of the ecoregion mappers have already lumped them. Our current thinking about the POSa region is that it is virtually identical floristically to the OPH and LLP regions minus some tree species. But even this is difficult to maintain because, in northern Texas, pine is a part of the POSa flora. Areas such as the Gus Engeling Wildlife Management Area (POSa) in Anderson County are identical edaphically and floristically to Woods County (OPH): POSa habitat simply exists in Wood County with pine on it (see Wilson 1990). This is also the case in such areas as the "Lost Pines" near Bastrop. In conclusion, we find Turner's (1959) analysis approximately what we envision.

APPENDIX

This is a survey of the biogeographers who have produced maps of the WGCP; they are reproduced so they can be understood and compared.

The literature describing and illustrating ecoregions was located by tracing bibliographical entries and by consulting Kuchler and McCormick (1965). Vegetation mapping of the WGCP did not begin in earnest until the twentieth century.

Several early botanists described WGCP vegetation but did not give maps. Without maps it is very difficult, if not impossible, to interpret ecoregion locations precisely; therefore, these descriptions are excluded from this review (e.g., Bray 1906; Warner 1926). Some authors present maps but add little to previous descriptions; these are also excluded from the present discussion (e.g., Allred & Mitchell 1955; McMahan et al. 1984). General accounts of early WGCP botanical research and descriptions of vegetation are given by Harper (1920), Tharp (1926), and Geiser (1948).

WGCP ecoregion terminology has never been standardized and any attempt to cross-index all usages would be almost impossible. We have, therefore, taken the liberty of standardizing it for this paper. Since we reproduce the maps, the reader need only see the relationship between various maps to judge similarities and differences.

The following abbreviations are used.

CPM = Coastal Prairie and Marsh Ecoregion
EGCP = East Gulf Coastal Plain
LLP = Longleaf Pine Ecoregion
OPH = Oak-Pine-Hickory Ecoregion
POSa = Post-Oak Savanna Ecoregion
PRA = Prairie Ecoregion
STP = South Texas Plains Ecoregion
WGCP = West Gulf Coastal Plain

We have redrawn all maps from the originals. This has been done to make them interpretable for present purposes. We have taken some liberties to clarify complicated maps. Scholars should consult original maps for detail and original terminology.

In this review—which is done chronologically—we are concerned mainly with geographical areas at and below the ecoregional level. Mapping at higher levels (region, province, subprovince) (Gleason & Cronquist 1964; Good 1974; Cronquist 1982; Takhtajan 1986) is not our concern, although,

since the "provinces" of Dice (1943), Takhtajan (1986), and Gleason and Cronquist (1964) in the WGCP are basically the same as ecoregions, we do discuss them.

Cooper (**1859**; see Stuckey 1978) developed one of the first province maps for North America (Fig. 3). He first described the distribution of tree species in North America and, while performing no statistical analysis, he recognized that different areas had d fferent combinations of species not found in other regions. His map, not dissimilar from that of Takhtajan (1986) and Gleason and Cronquist (1964), was still being reproduced almost a century later (Dayton 1949). He divided North America into provinces and regions. Two provinces interest us: the Appalachian (eastern wooded) and the Campestrian (prairie). We have separated these by a heavy line. He divided each into five regions (we show only four for the Campestrian). The pattern later to be found in many ecoregion and province maps is clearly evident here.

Transeau (**1903**; see also Stuckey & Reese 1981; Delcourt & Delcourt 2000), following in the footsteps of Sargent (1881), produced a simple map of North American vegetation (Fig. 4). His few vegetation types are of interest only in that he included the Cross Timbers and POSa regions in the eastern deciduous forest type and separated the coniferous forest type (what later would become known as the LLP ecoregion).

Harshberger (**1911**) produced perhaps the first widely recognized phytogeographical map of North America, according to which the Atlantic-Gulf Coastal region encompasses most of east Texas and west Louisiana (Fig. 5). To the west of the Atlantic-Gulf Coastal region, Harshberger showed what he called the Ozark area of the Alleghenian-Ozark district, which today would be called the POSa and Cross Timbers ecoregions (POSa on map). Note that the area designated extends well north of Texas. Also note that south and west of this "Ozark area" is a PRA region as well as several other vaguely described regions that extend to the Texas coast. The southernmost, his "Gulf region of the Mexican phytogeographic province," would be our STP. But the others do not fol ow current usage. The western-most is his "Edwards Plateau forest, meeting ground for species of Atlantic, Rocky Mountain and Mexican forests" (EP on map). The center area is nis "Transition Prairie Forest district, comprising the oak openings" (TRAN on map). This region is a phytogeographic southern disjunct from Wisconsin, Iowa, and Illinois. The final region is his "Texas cross timber and coastal plain belt of heavy live oak with prairies sandwiched between." This today constitutes part of the CPM ecoregion but extends farther inland. Harshberger's use of "cross timber" here is confusing to the modern biogeographer. Also note that the limits of longleaf pine (and many other trees) are shown on his original map but that no longleaf pine ecoregion is recognized. But the salient features of the Harshberger map are that east Texas floristically is firmly joined to the Gulf and Atlantic Coastal plains, and tne POSs region is clearly recognized. There are several reprints of Harshberger (1911) but with black and white maps. These are difficult to interpret, and only the colored map of the first edition is satisfactory.

Shreve (**1917**) virtually established the modern WGCP pattern (Fig. 6). He distinguished three WGCP forest regions. The POSa region extends unbroken from south Texas to Michigan, the LLP region extends from southeastern Texas to Florida and North Carolina, and the OPH region extends from Texas to Virginia. This pattern, as will be seen, was followed with very little modification by such influential biogeographers as Braun (1950) and Kuchler (1964). Shreve's original map is in color and cannot be interpreted from black and white reproductions of which there are many.

Shantz and Zon (**1924**), in their widely reproduced map, added essentially nothing to Shreve (Fig. 7). The Shantz and Zon map has been widely reprinted, sometimes with minor modificat ons (Fenneman 1938; Barrett 1962; Fowells 1965).

Tharp's (**1926**) interest was regional (Fig. 8). He mapped Texas east of the 98th Meridian and did extensive field work throughout east Texas. He provided extensive descriptions of the vegetation regions. His captionless map (his plate III) is confusing, and the text requires careful study for complete interpretation. But his map is the basic pattern that is familiar today: a LLP region in southeast Texas, a coastal region, an OPH region to the north and west of the LLP region, and a

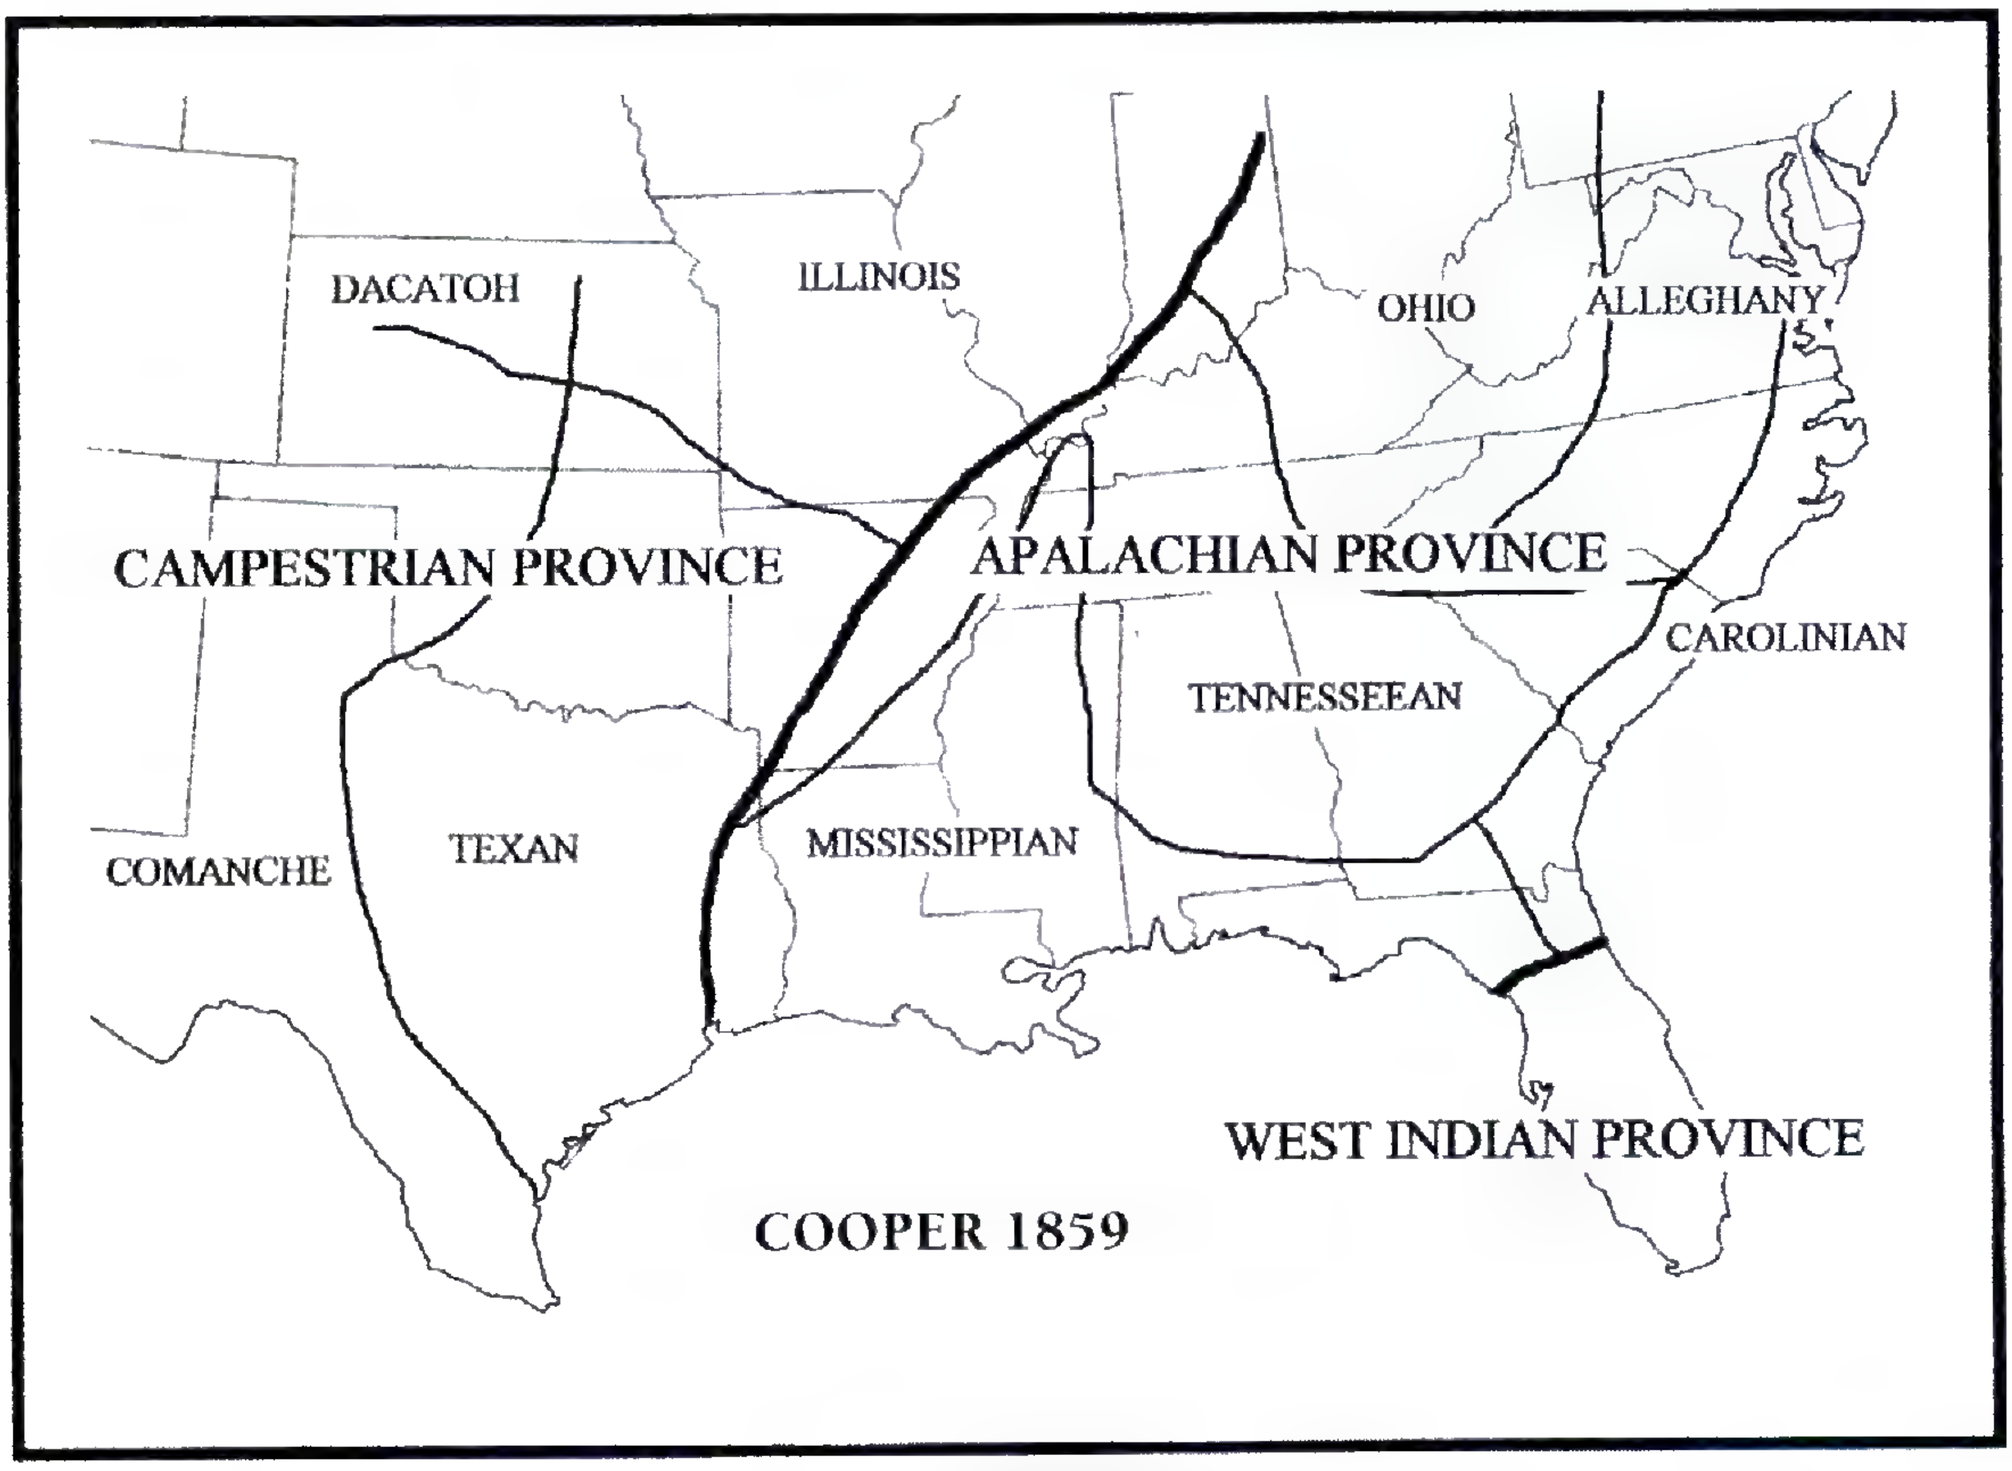

FIG. 3. Vegetation areas according to Cooper (1859).

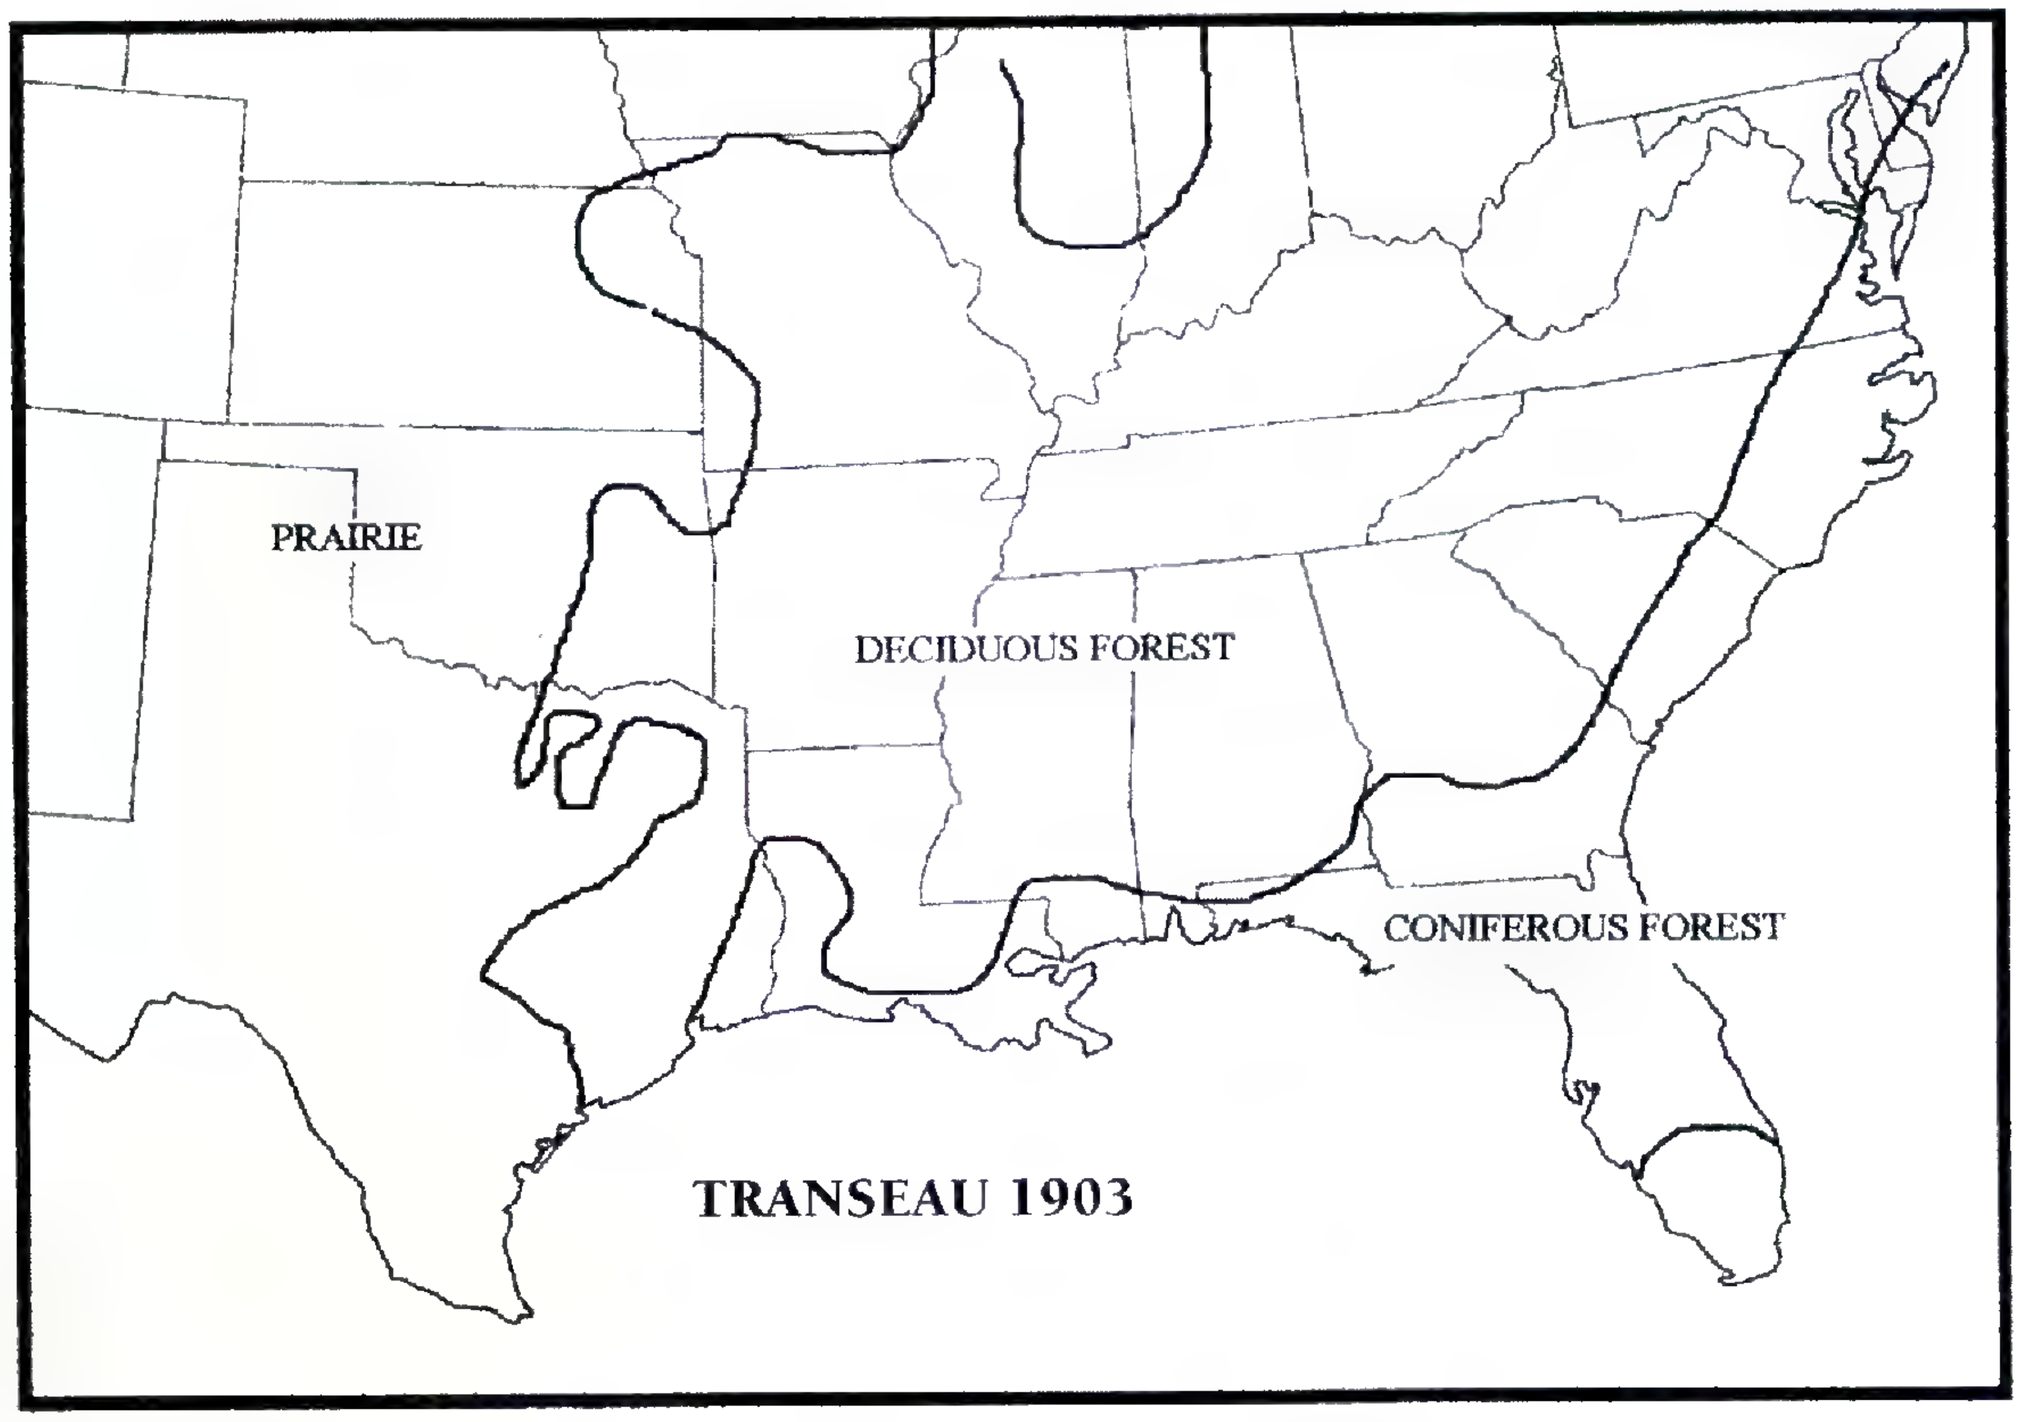

FIG. 4. Vegetation areas according to Transeau (1903).

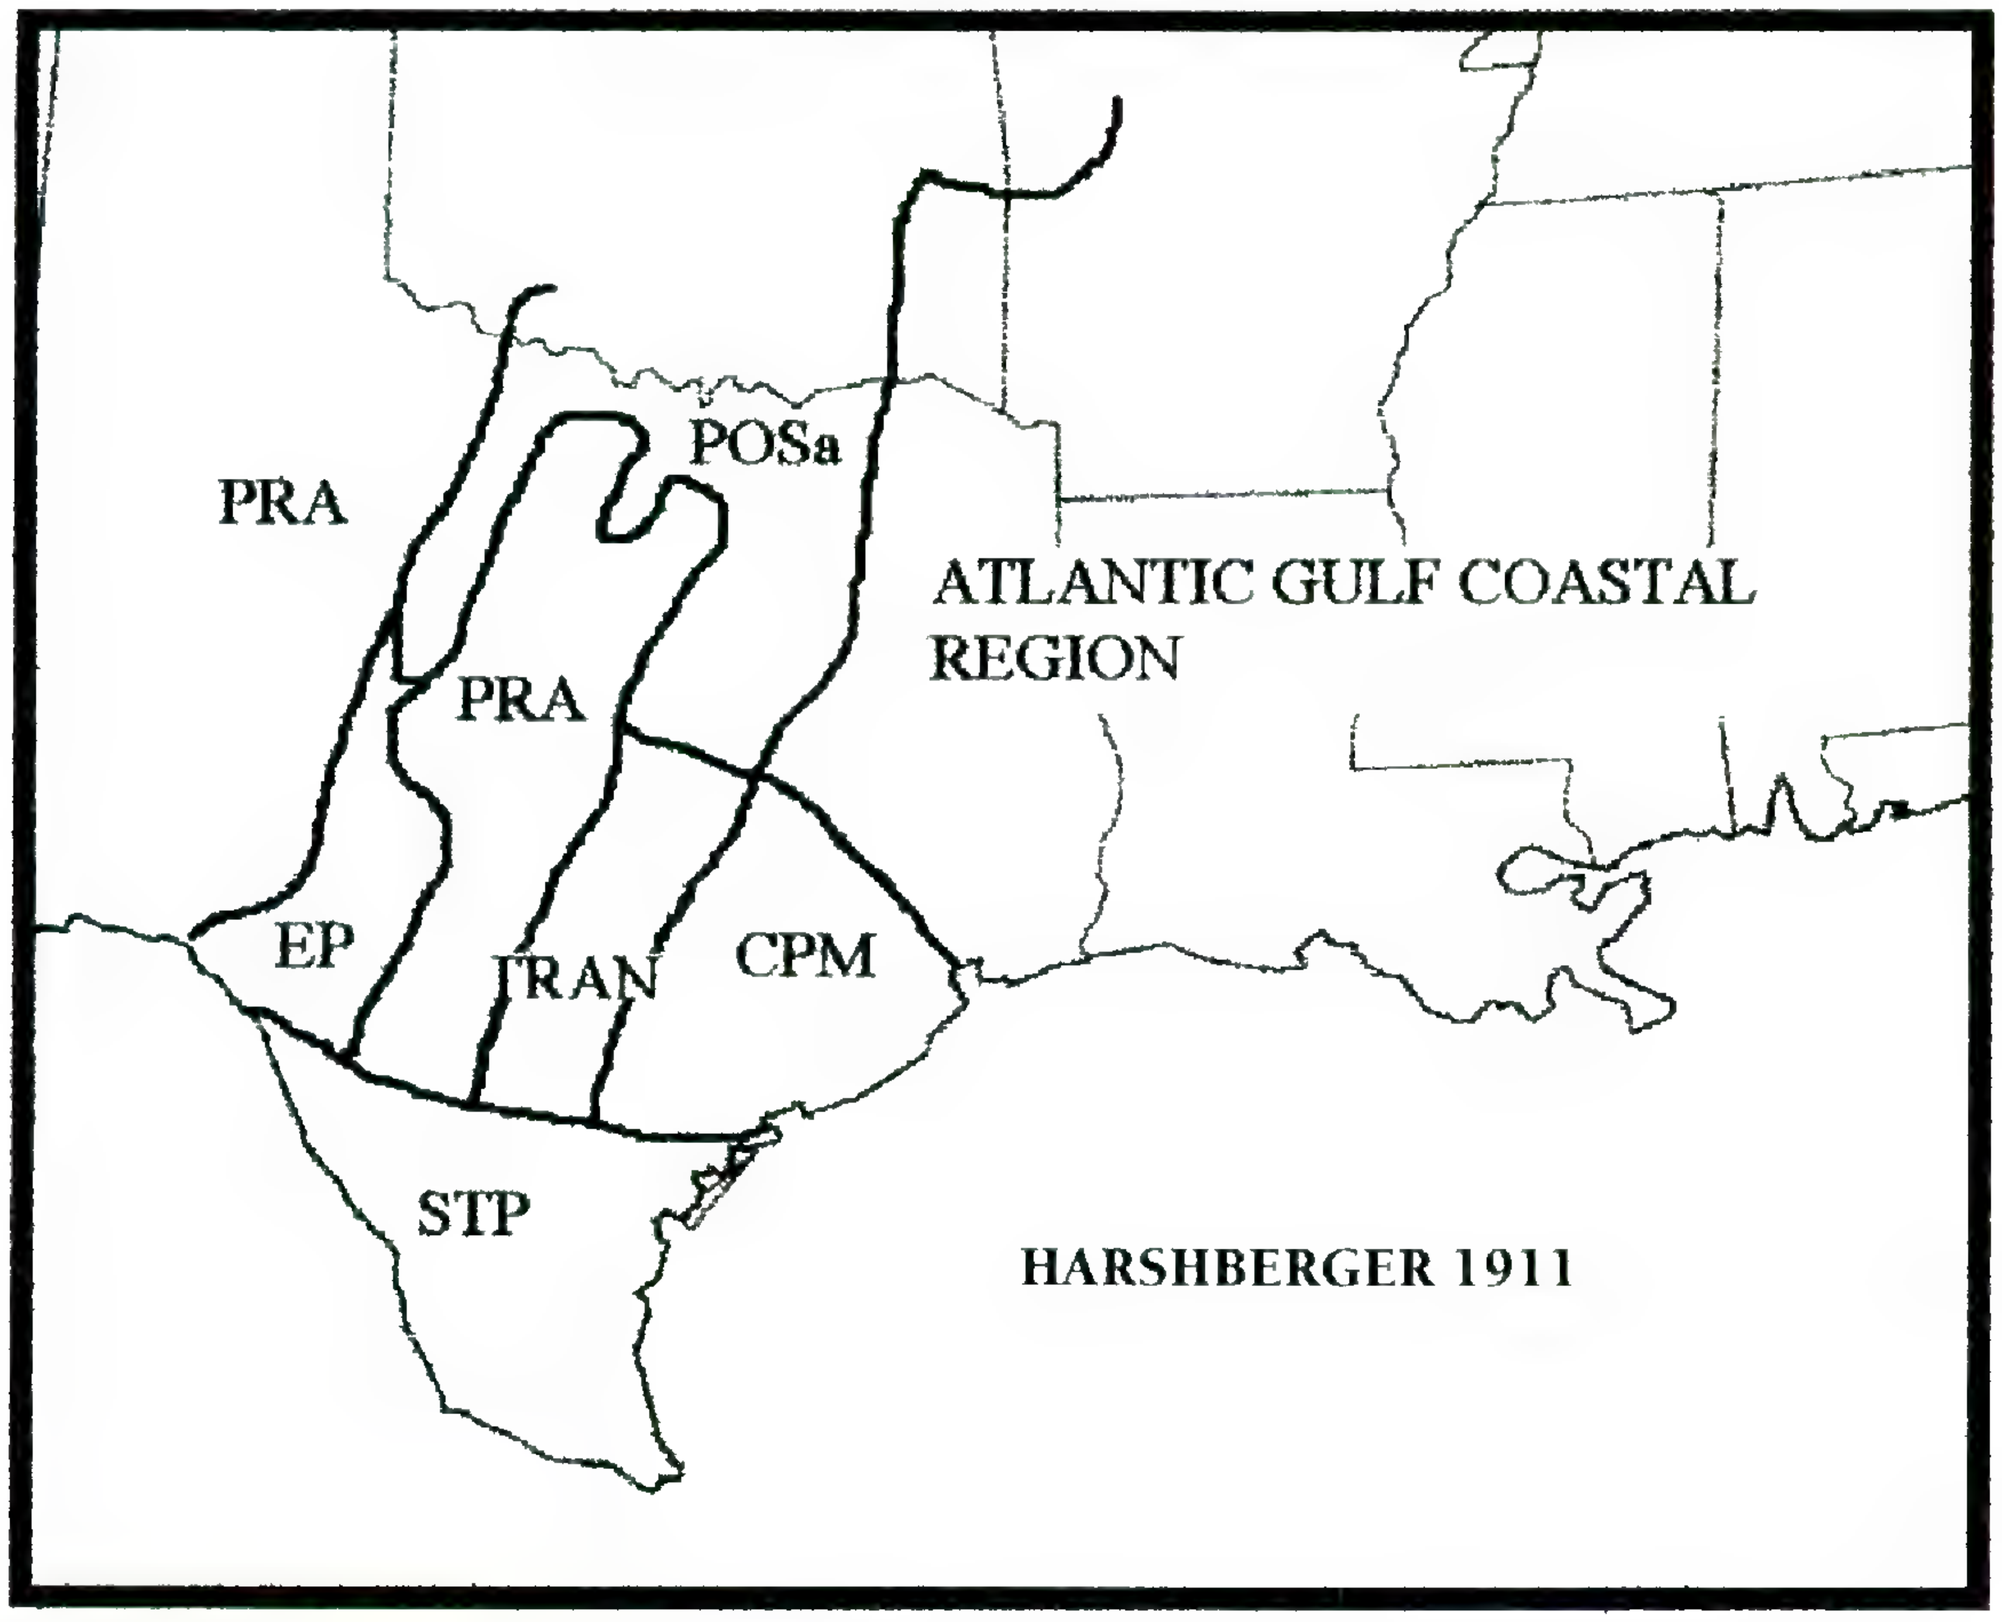

Fig. 5. Vegetation areas according to Harshberger (1911).

POSa region to the west of the OPH region. Tharp divided the POSa region into two areas. To the north, prairies are not common but to the south is an "oak-prairie mictium," that is, a combination of POSa and prairie southwest of the Brazos River. Later biogeographers showed this area as POSa with islands of prairie in it (e.g., Gould 1962; Diamond & Smeins 1988).

Carter (1931), the chief soil scientist for the Texas Agricultural Experiment Station, in his survey of the soils of Texas, produced a vegetation map for the whole state (Fig. 9). The accompanying soil map, while not matching the vegetation patterns precisely, does delineate the distribution of "main areas of deep sands" that correspond closely with the POSa region. Descriptions of the regions are given in his text.

Fenneman (1938) produced a slightly modified Shantz and Zon (1924) map (not reproduced here). He filled in the non-forested areas along the coast of Louisiana and Texas that they left blank. A modified version of this map is in Bonnicksen (2000).

Tharp (1939) refined his regional vegetational map (Fig. 10). In this version, the lines that were tentative in 1926 are bold. The WGCP is virtually identical to that given by Carter (1931), and any comparison of Tharp's map to that of Gould twenty years later leaves no doubt about influences. Tharp's brief descriptions of the vegetational regions are often folksy but never dull. Tharp's map was used by Wynd (1944).

Dice's (1943, 1968) "biotic provinces" are at a descriptive level above the ecoregion (Fig. 11). In this scheme, Dice divided east Texas into two regions: the Austroriparian and the Texan. The Austroriparian encompasses basically the entire Atlantic and Gulf Coastal Plain (OPH and LLP). The

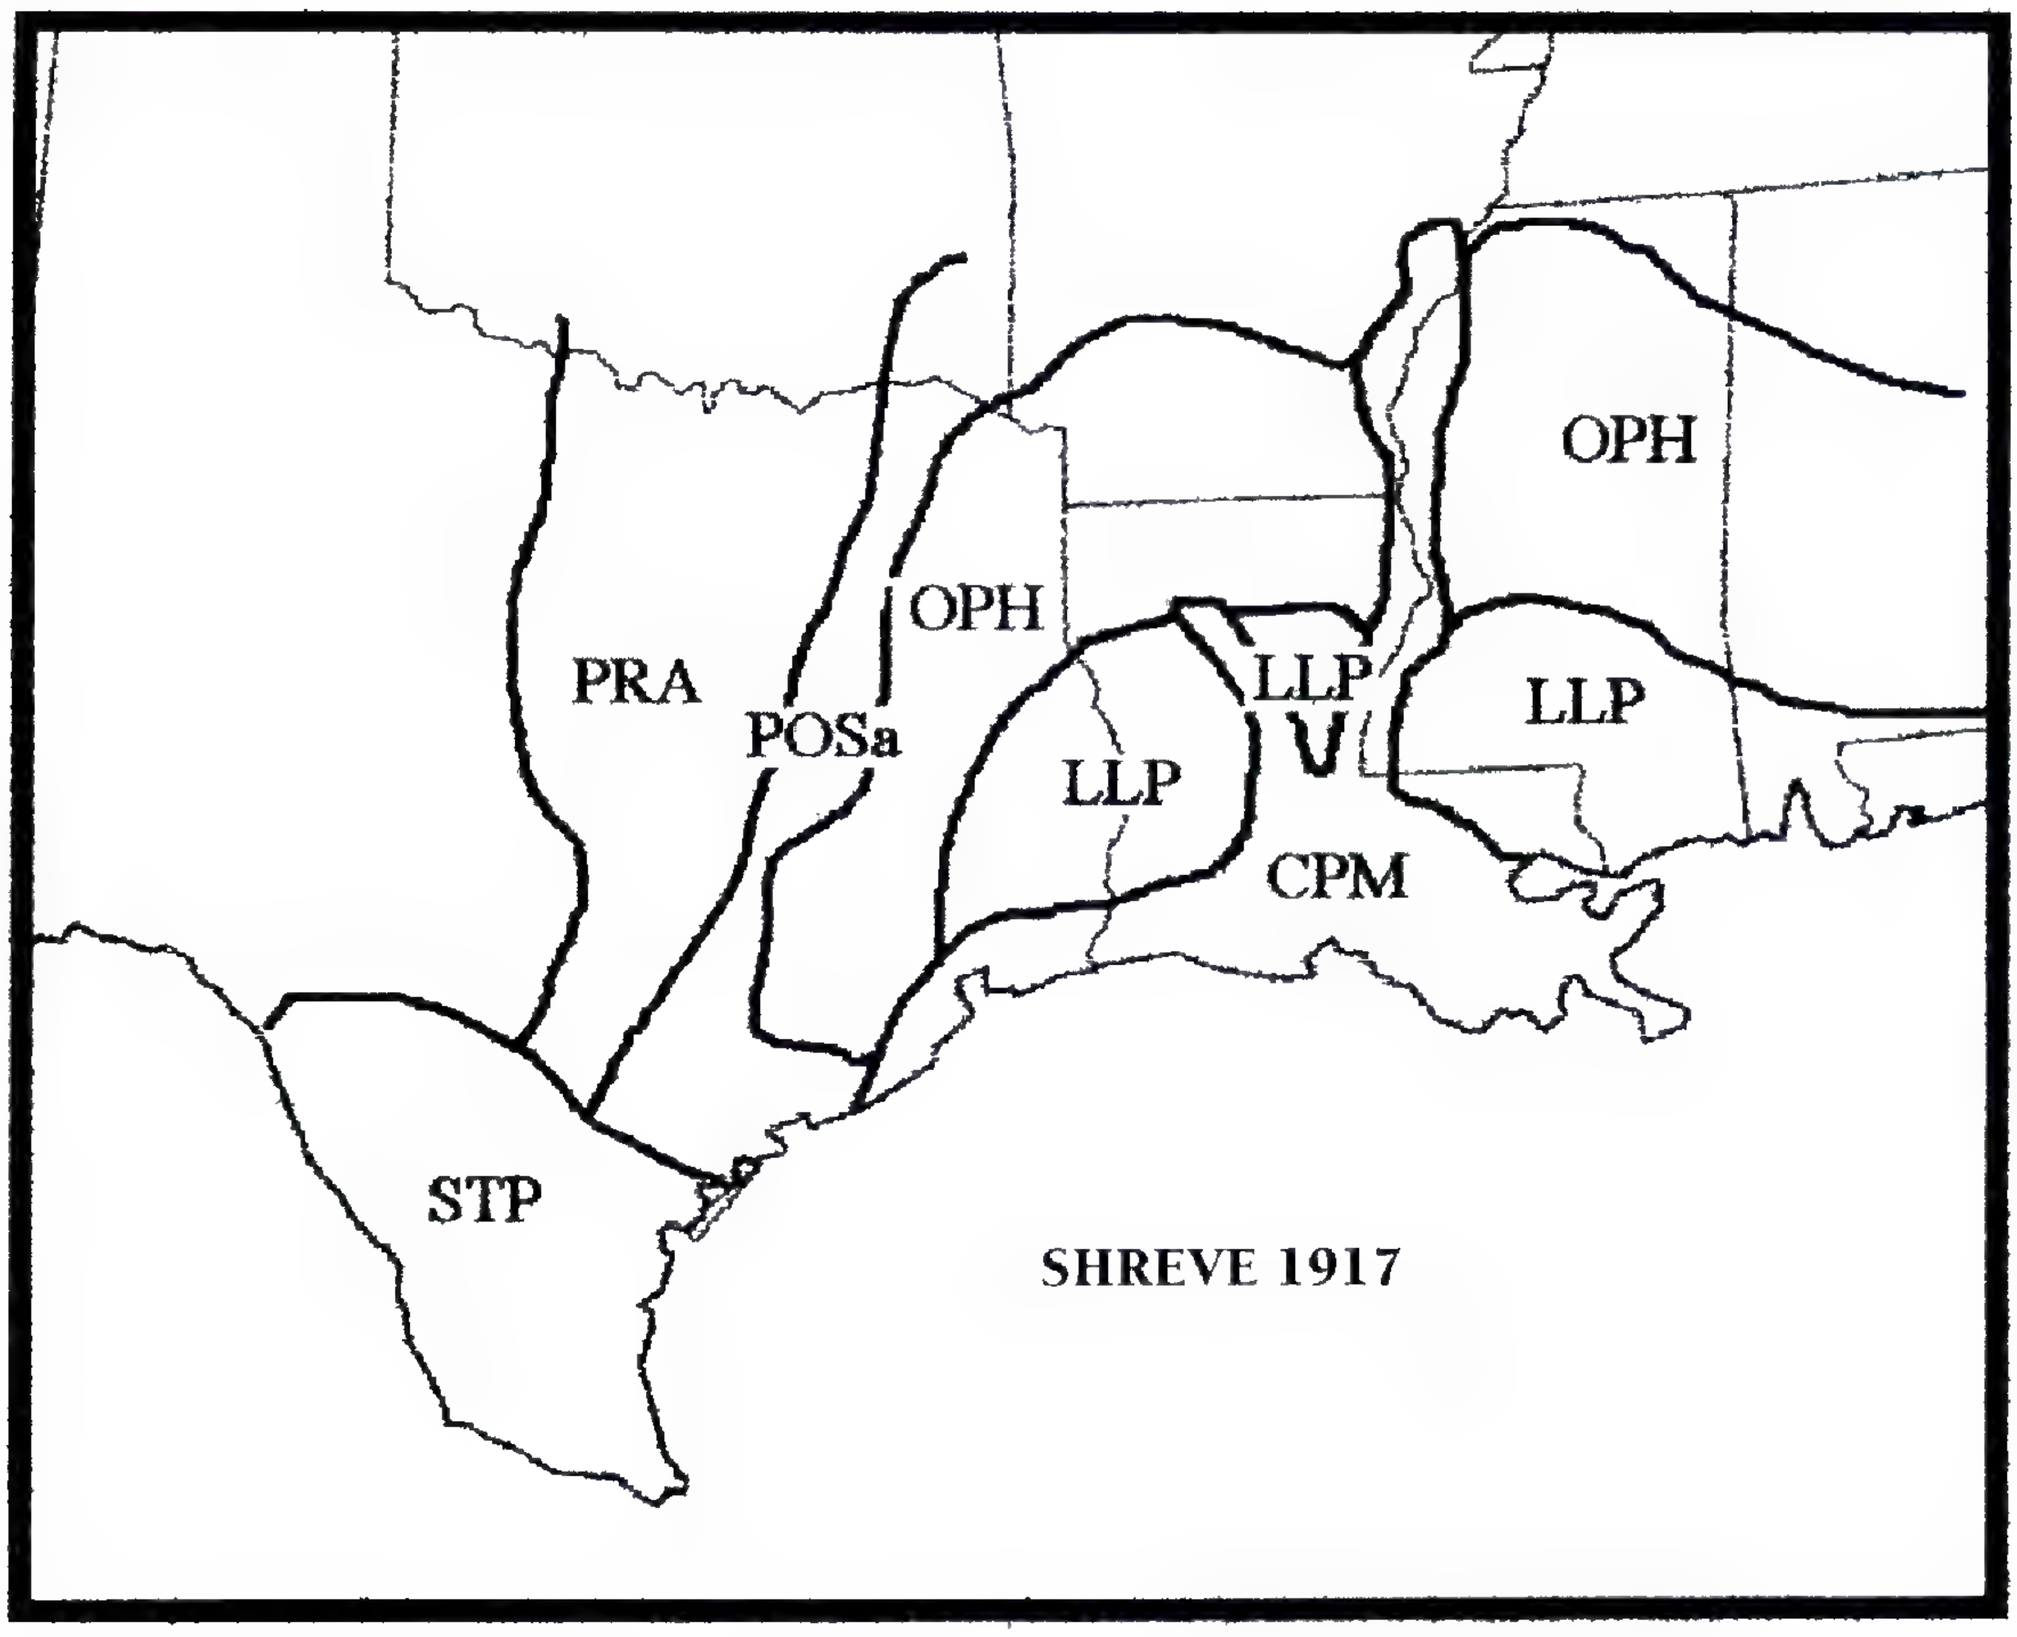

Fig. 6. Vegetation areas according to Shreve (1917).

Texan takes in the POSa as well as the prairies and cross timbers regions, and extends from central coastal Texas to northern Oklahoma. Blair (1950) followed Dice in his description of the east Texas biotic provinces but added nothing.

Braun's (1950) classic work on eastern forests adds little to our knowledge of the WGCP region (Fig. 12). Her map of "Forest Regions" is essentially identical to that of Shantz and Zon (1924) with only minor boundary shifts. She kept the three "regions" format: LLP, OPH, and POSa. While Braun sampled vegetation widely across the east, and produced tables of percent composition from many sites, but none from the WGCP, she did not statistically compare regions, but left that to her successors (e.g., Delcourt & Delcourt 2000).

Tharp's (1952) final map (not reproduced here) of the vegetation regions represents revisions and refinements of maps in his 1926 and 1939 publications. The greater detail is based on a decade of additional field experience, but the refinements for the WGCP are relatively minor and add little to his earlier work. Consequently, we do not present a separate map; however, it should be noted that his brief descriptions of each vegetation region are succinct and clear.

Turner (1959) is unique among WGCP authors in that ne used quantitative methods to determine what he calls "floral provinces" (Fig. 2). We have discussed his work in the first part of this paper.

Gould's (1962) map is clearly influenced by Carter's (1931) and Tharp's (1926, 1939, 1952) work (Fig. 13). The map and slight variants have been used extensively (e.g., Correll & Johnston 1970; McMahan et al. 1984; Hatch et al. 1990; Diggs et al. 1999) and one version of it presents subregions (e.g. LBJ School of Public Relations 1978; Diamond et al. 1987; Telfair 1999).

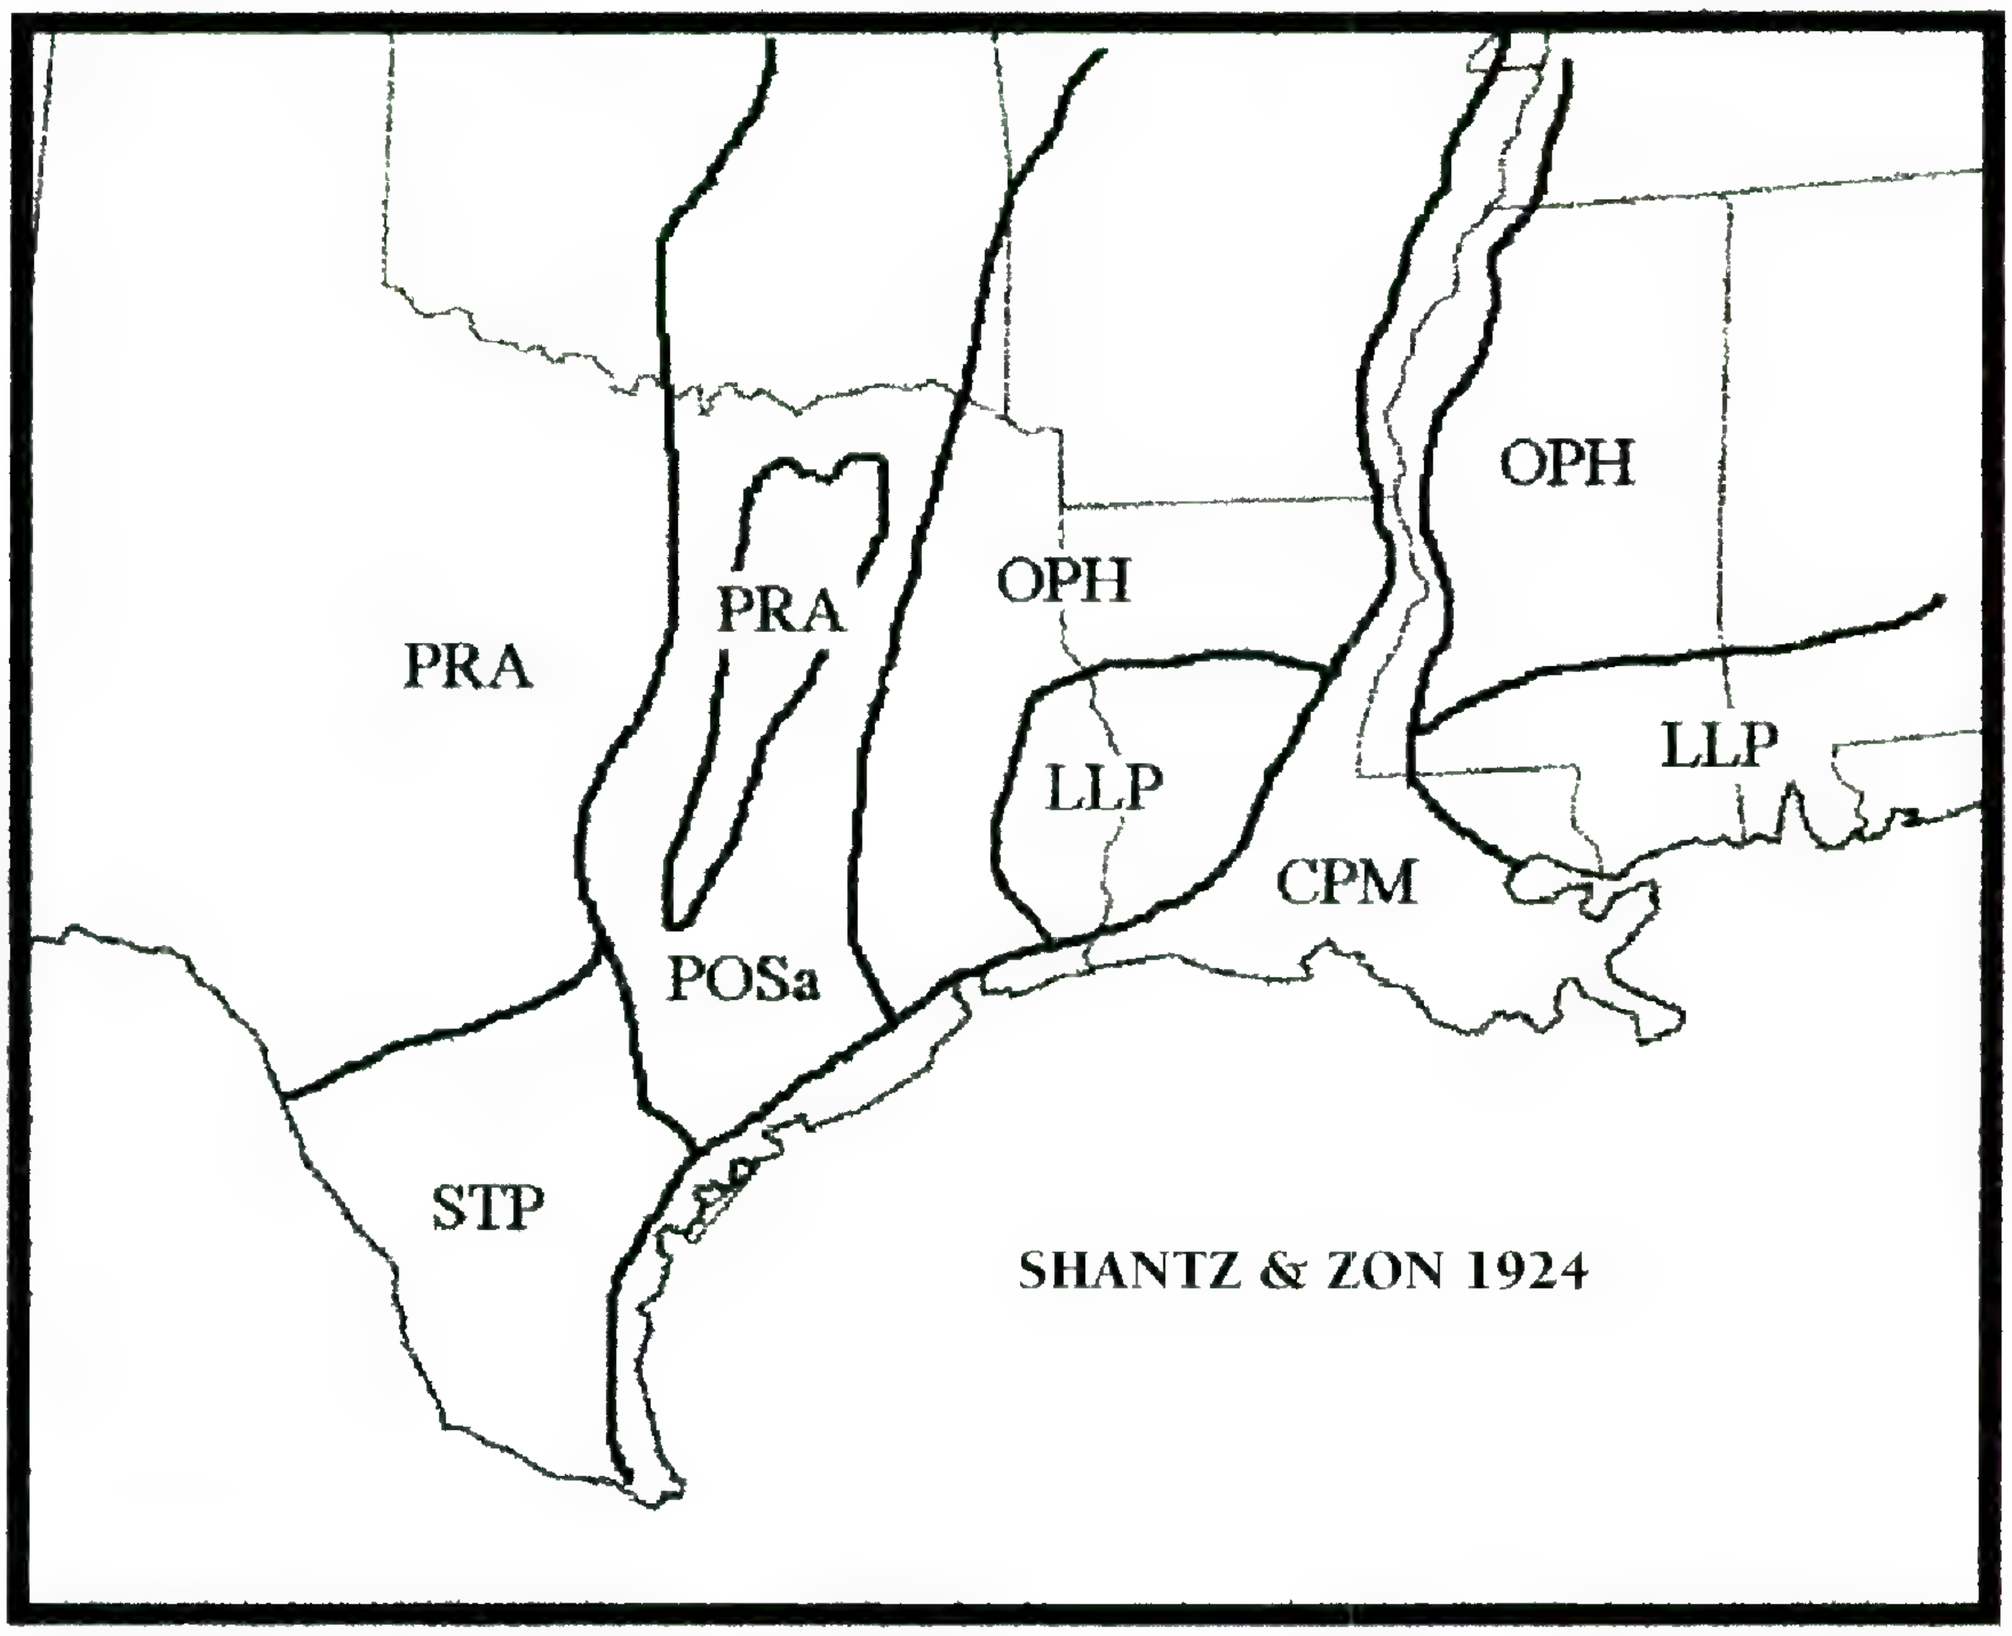

Fig. 7. Vegetation areas according to Shantz and Zon (1924).

Gleason and Cronquist (1964) detailed ten floristic provinces of North America, four of which occur in the WGCP (Fig. 14). What is of interest to us in this map is the association of the POSa region, notably regions as far south as Guadalupe County in Texas, with regions as far north as Maine, southern Ontario, Michigan, and Minnesota: this entire area Gleason and Cronquist called the Eastern Deciduous Forest Province. The floristic similarity among extreme parts of this large region is very small indeed. At the same time, their Coastal Plain Province is nothing more than the traditional Atlantic and Gulf Coastal Plain that extends from east Texas to Florida and north to Virginia—a much more floristically homogeneous region than the Eastern Deciduous Forest Province. Takhtajan (1986) produced a province map of North America virtually identical to that of Gleason and Cronquist (1964), which has been reproduced (Thorne 1993) (Fig. 15).

Kuchler's (1964) map, "Potential Natural Vegetation of the Conterminous United States," has become the "central dogma" of North American biogeographers upon which all other maps are judged (Fig. 16). It is widely cited and used (e.g., Martin et al. 1993). The Kuchler map presents no novelties for the WGCP; it is virtually identical with those of Shantz and Zon (1924) and Braun (1950).

Mahler (1981) presented an interesting variation on the Gould (1962) map (Fig. 17). Apparently following the lead of McLeod (1971), he designated not a LLP ecoregion in southeast Texas but a Beech-Magnolia-Pine-Oak-Sweet Gum (Big Thicket) region overlying most of the traditional LLP ecoregion. Why Mahler (1981) chose this course is not clear, but it underlines the fact that other ecoregion descriptions can be considered.

Omernik's (1986) was the first ecoregion map where ecoregions no longer straddle the Mississippi River (Fig. 18). Additionally, Omernik did not divide the pineywoods region into two

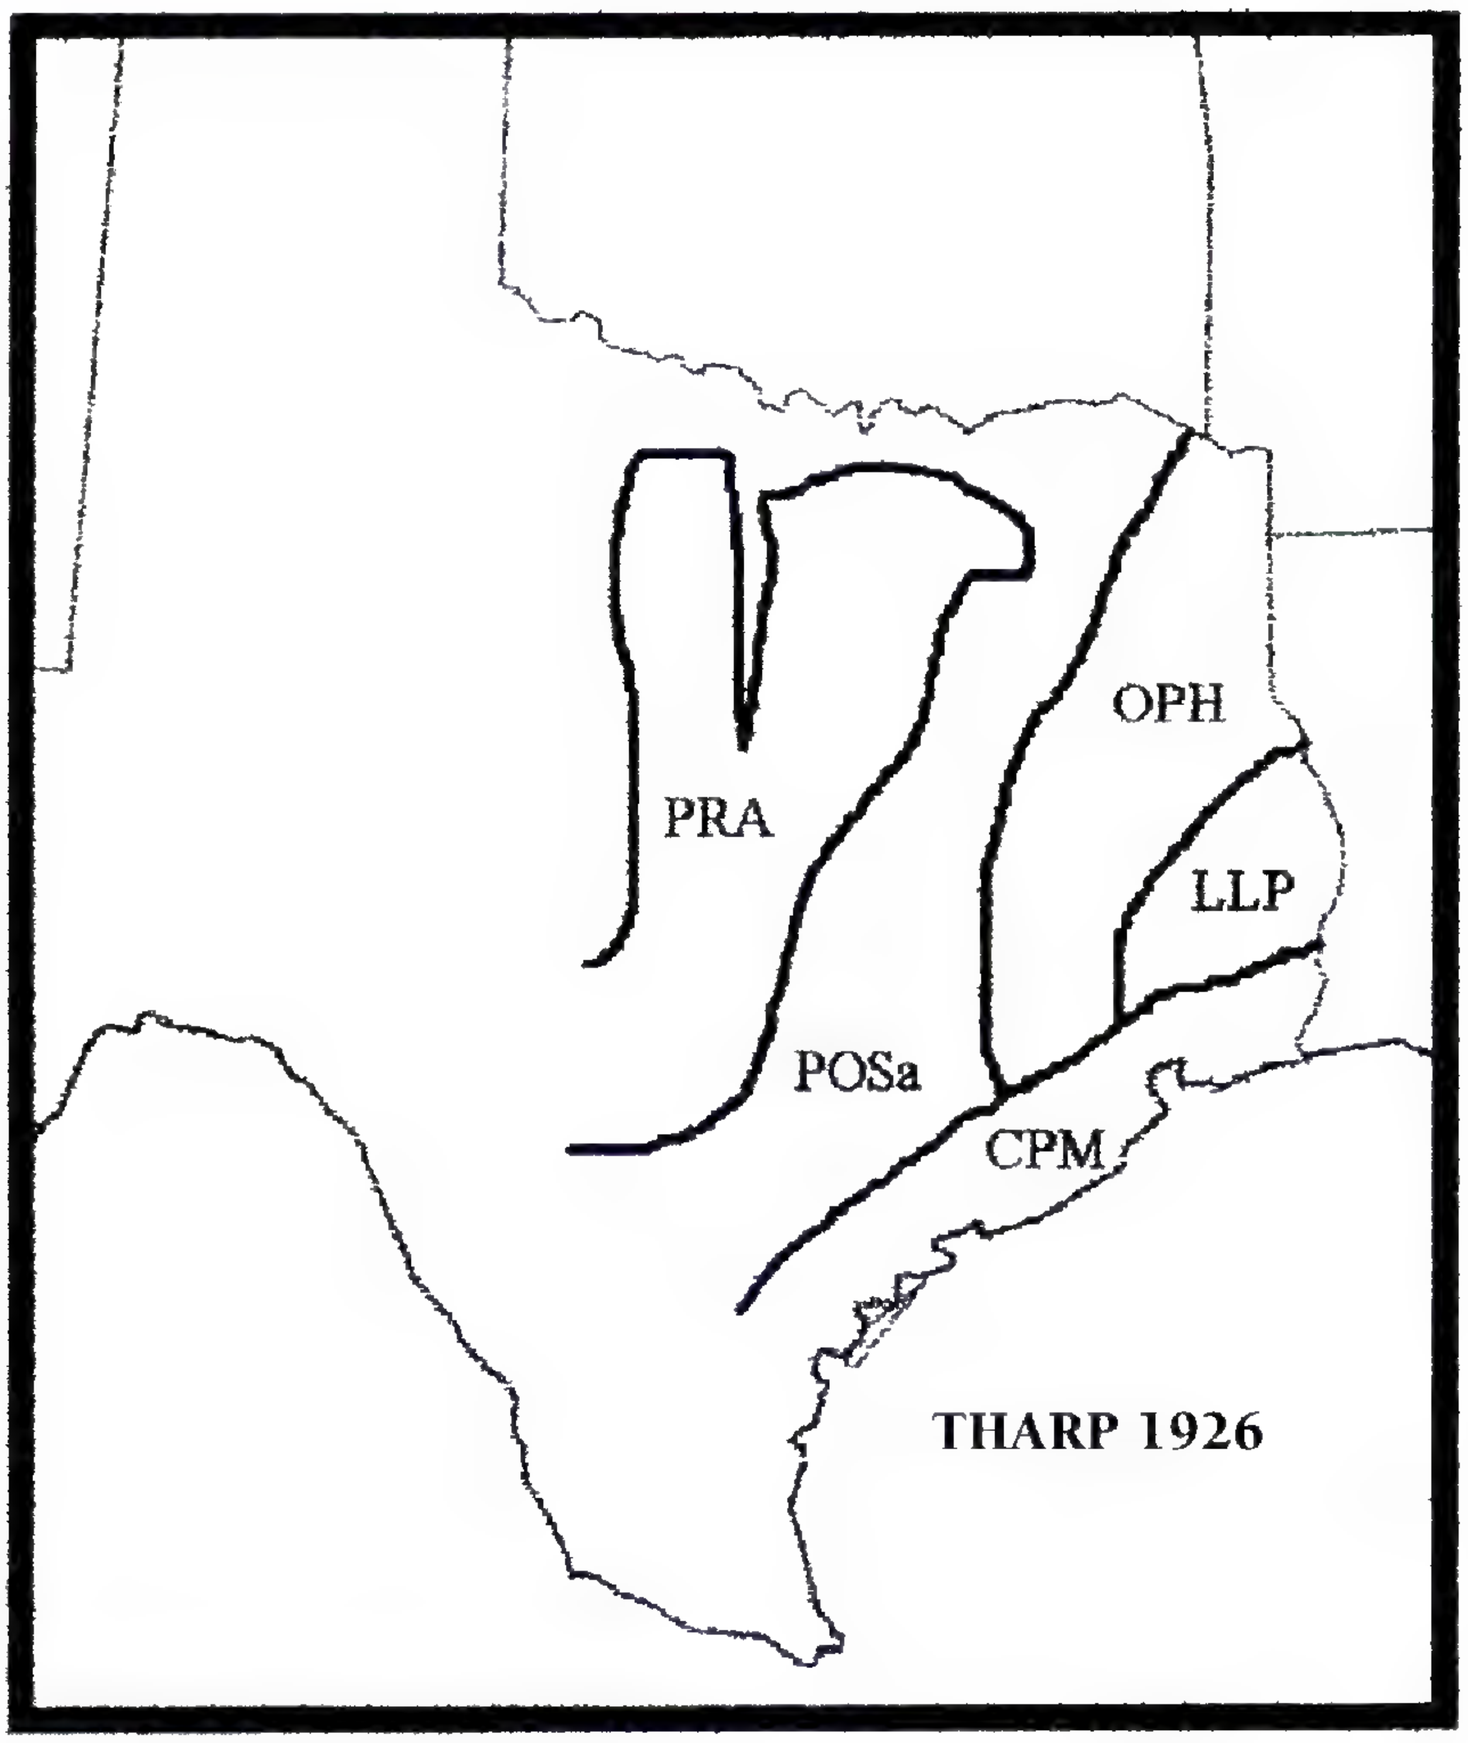

Fig. 8. Vegetation areas according to Tharp (1926).

ecoregions (OPH and LLP) but like Gould (1962) kept them together. Otherwise, the familiar pattern is maintained. But what is interesting here is that the LLP region is not uniquely distinguished in either the WGCP or EGCP. How Omernik distinguished EGCP ecoregions from WGCP ecoregions is not evident since his brief descriptions are virtually of no help.

Greller (1988) produced a map that he claims is based on Braun (1950) but which shows no closer relation to hers than it does to the maps of Shantz and Zon (1924) or Kuchler (1964) (Fig. 19). What is unique about Greller's map is that it combines the POSa and the OPH regions with no explanation given (but see Turner 1959). Greller did, however, retain the other traditional ecoregion features, such as the LLP ecoregion.

Barbour and Christensen (1993) presented a relatively simplified vegetational map of North America (Fig. 20). We find in it the traditional LLP and OPH regions, but the POSa region has been separated and joined into a vast region stretching from the Gulf of Mexico to Canada. This region is described as "tallgrass prairie, including the prairie peninsula and oak savanna ecotone with the eastern deciduous forest" (1993:98). Treating the POSa region as an "ecotone" and including it in the prairie ecoregion has been commented on (Gehlbach 1991) and is reminiscent of Dice's (1943, 1968) and Blair's (1950) "Texan" biotic province.

Bailey et al. (1980, 1994, see also DeGraaf et al. 1988; McNab & Avers 1994) resurrected the old Texan biotic province of Dice (1942, 1968) and Blair (1950), and then divided it into four subregions (Fig. 21). This ecoregion ("province" and "ecoregion" are apparently synonyms here) extends

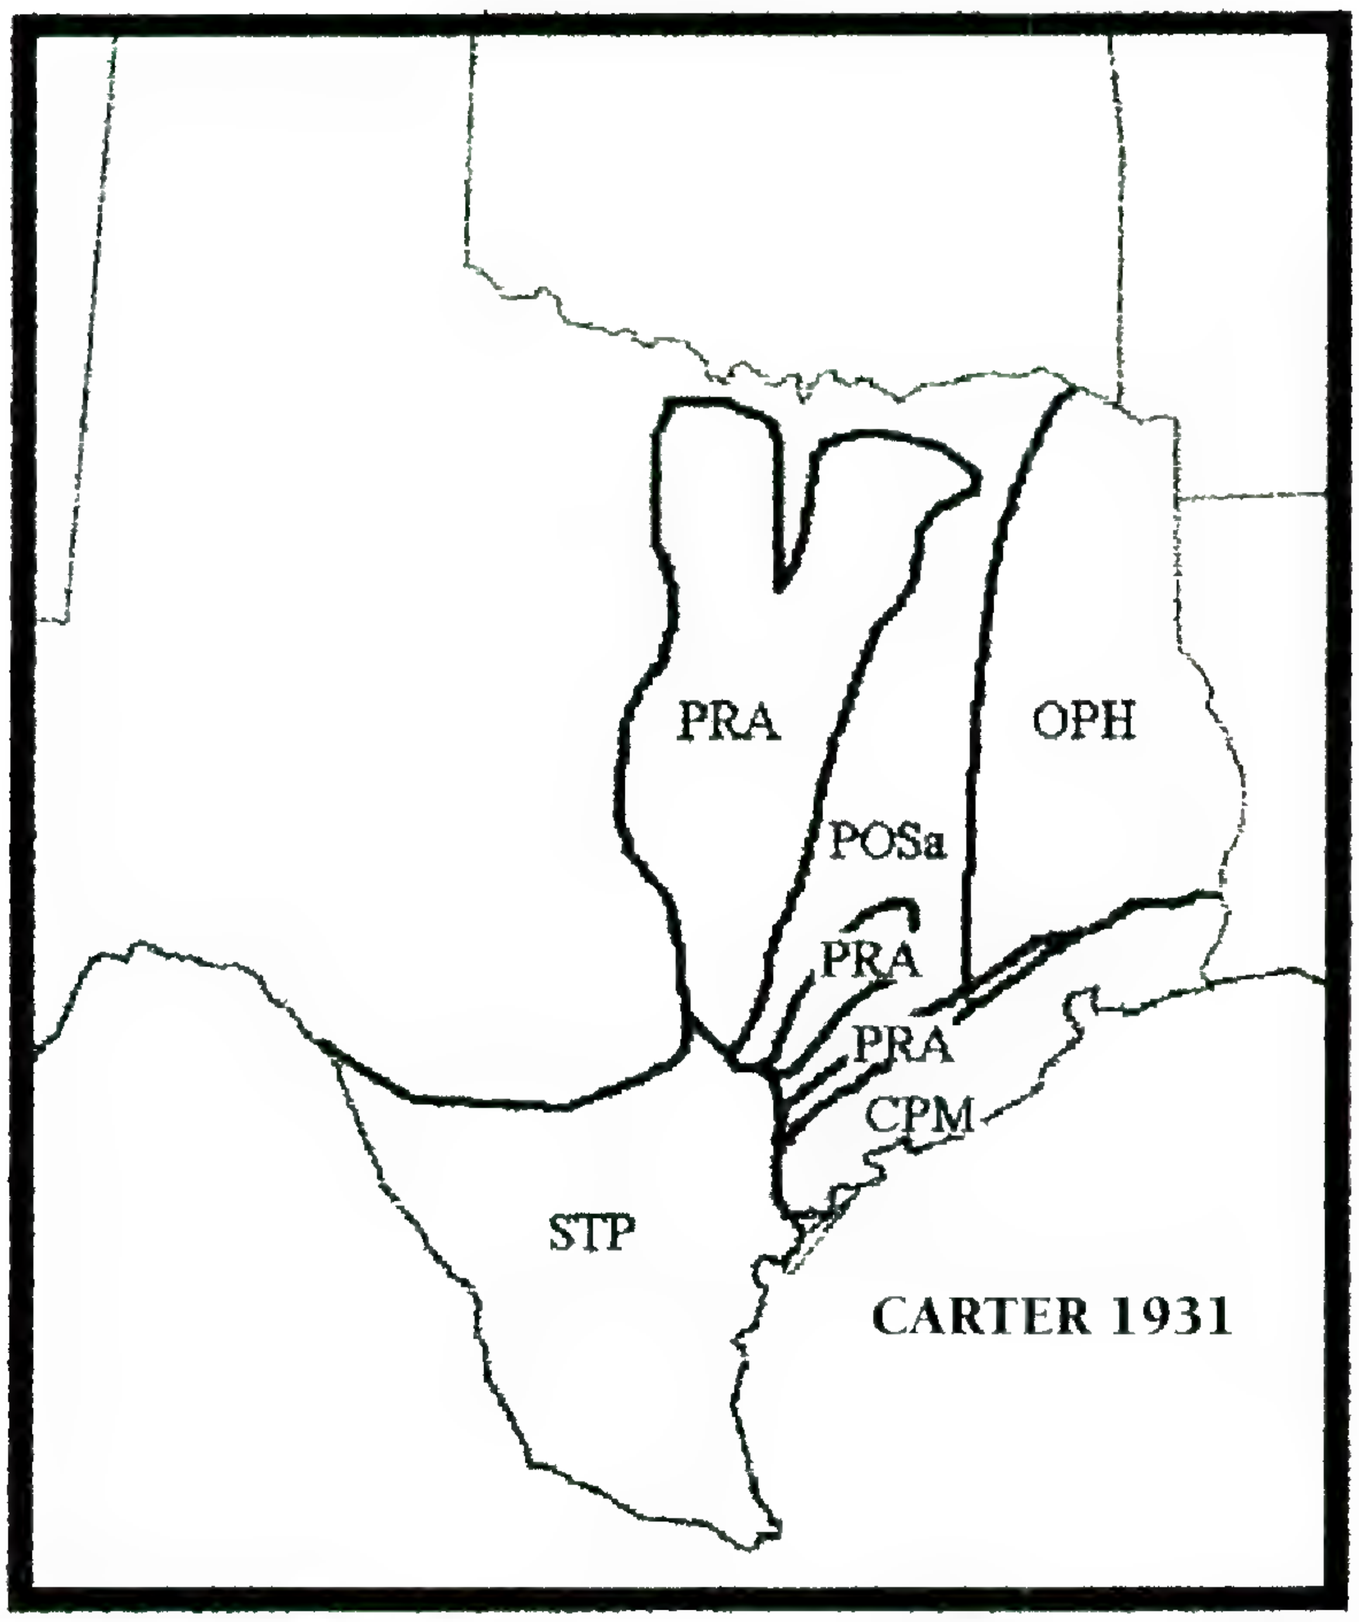

Fig. 9. Vegetation areas according to Carter (1931).

from the Texas coast to northern Oklahoma. The eastern most part is separated as the "Oak woods and prairies subregion" (255C), which is virtually identical to the POSa region of previous writers except that it includes several major sections of the prairie region of east Texas, such as Fayette Prairie. This makes the Bailey "Oak woods and prairies subregion" non-comparable with the maps of most other biogeographers. Like many before them Bailey et al. (1994) divided the remainder of the WGCP in two regions. The southern one corresponds with the LLP, and the northern one corresponds to OPH. At the subregional level, nowever, they separated botn the OPH and the LLP regions west of the Mississippi River from the OPH and LLP regions east of the Mississippi River. What distinguishes these areas, aside from geographical location, is not disclosed, and the McNab and Avers (1994) descriptions do not help. It should be further noted that the Bailey (1994) text and the McNab and Avers (1994) descriptive material are peppered with factual mistakes, something not found in previous biogeographic descriptions.

The map of **Keys et al. (1995)** and **Bailey (1994)** are virtually identical. Because the Key et al. (1995) map is more detailed, the western boundary of the WGCP is more easily distinguished (Fig. 22). The northern POSa region may have been included in the OPH region while the southern POSa may have been included with the Prairies sections. Bailey et al. (1994) may have done this also, but that map is cruder and harder to decipher: they may have put the entire POSa region in with the prairie group. The Keys et al. (1995) map divides ecoregions into dozens of "nested" subsections that are not readily distinguishable on the basis of their descriptions (nor are they distinguished by regional ecologists and botanists). Also, the Keys et al. (1995) map is clearly based on a poor knowledge of the WGCP. The text presents several factual mistakes.

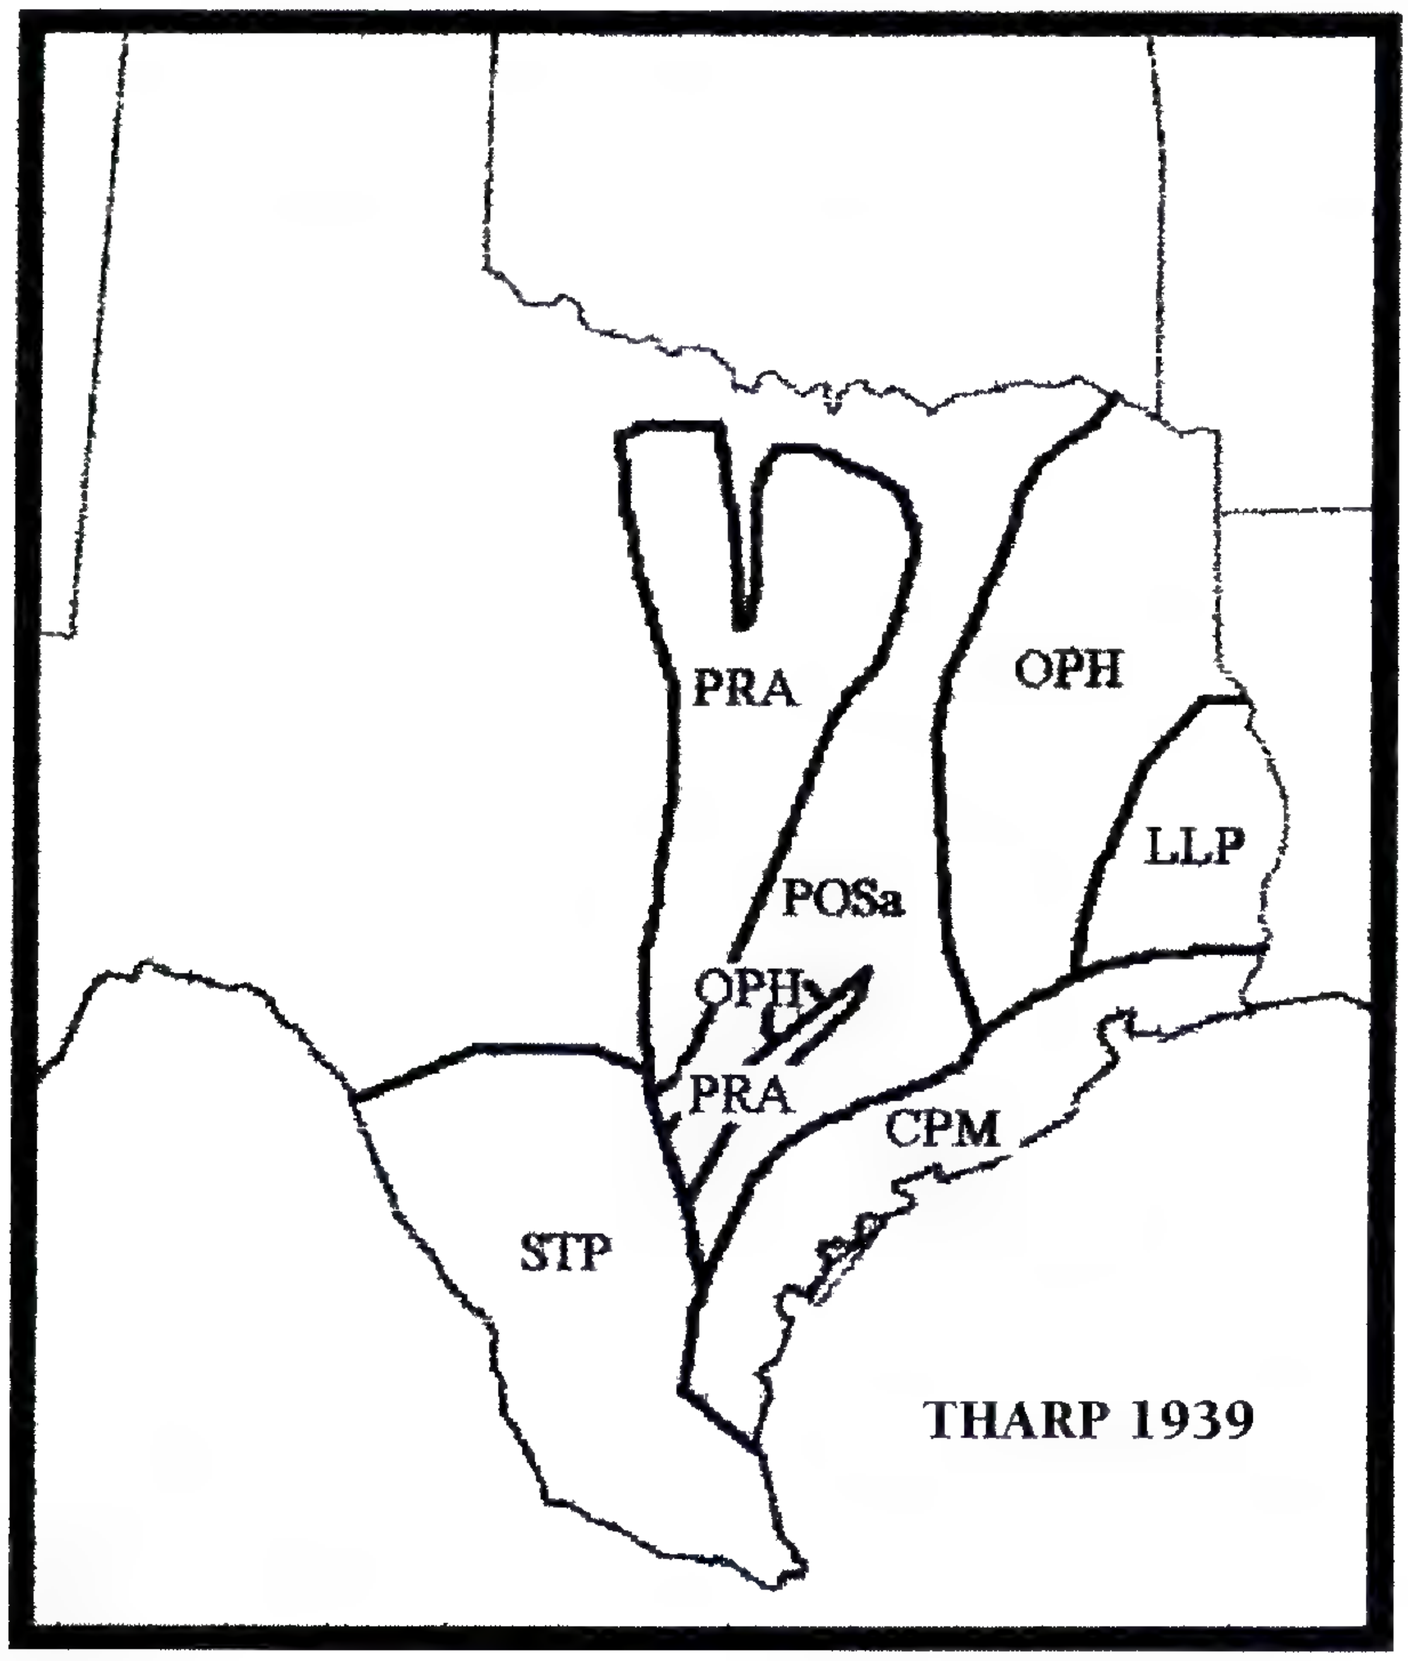

Fig. 10. Vegetation areas according to Tharp (1939).

The Nature Conservancy (**Weakley et al. 1998**; Turner et al. 1999) relies heavily on Keys et al.(1995) and Bailey et al.(1994), and it is through the Nature Conservancy maps that it is possible to detail precisely where the Keys et al. (1995) ecoregions, provinces, sections, and subsections are (Fig. 23). The POSa region has disappeared as a region. In the north, it is divided between the prairies region and the "Upper West Gulf Plain" region. In the south, the "West Gulf Coastal Plain" region is basically coterminous with Longleaf pine. This new terminology should lead to confusion.

Ricketts et al. (**1999a, 1999b**) divided North America into two phytogeographic levels. The first is ten Major Habitat Types in which most of the WGCP is lumped with the LLP region and not with the OPH region of the east, and the POSa region is lumped with the majority of the east but is geographically separated from it. At the finer level, in the WGCP the traditional LLP and OPH regions are lumped into the "pineywoods region;" whereas in the EGCP, they are inexplicably kept separate. The POSa region is separated from the "pineywoods." In the EGCP, while the traditional LLP and OPH regions are recognized, they are ignored in the WGCP. The descriptive sections of this account are replete with factual mistakes, and it is clear that part of the problem is a heavy reliance on Bailey et al. (1994). Ricketts et al. (1999a, 1999b) apparently believe that longleaf pine occurs over the entire "pineywoods" region. Since the Ricketts et al. maps of the WGCP are identical with Omernik's map, the reader is referred to that map for detail.

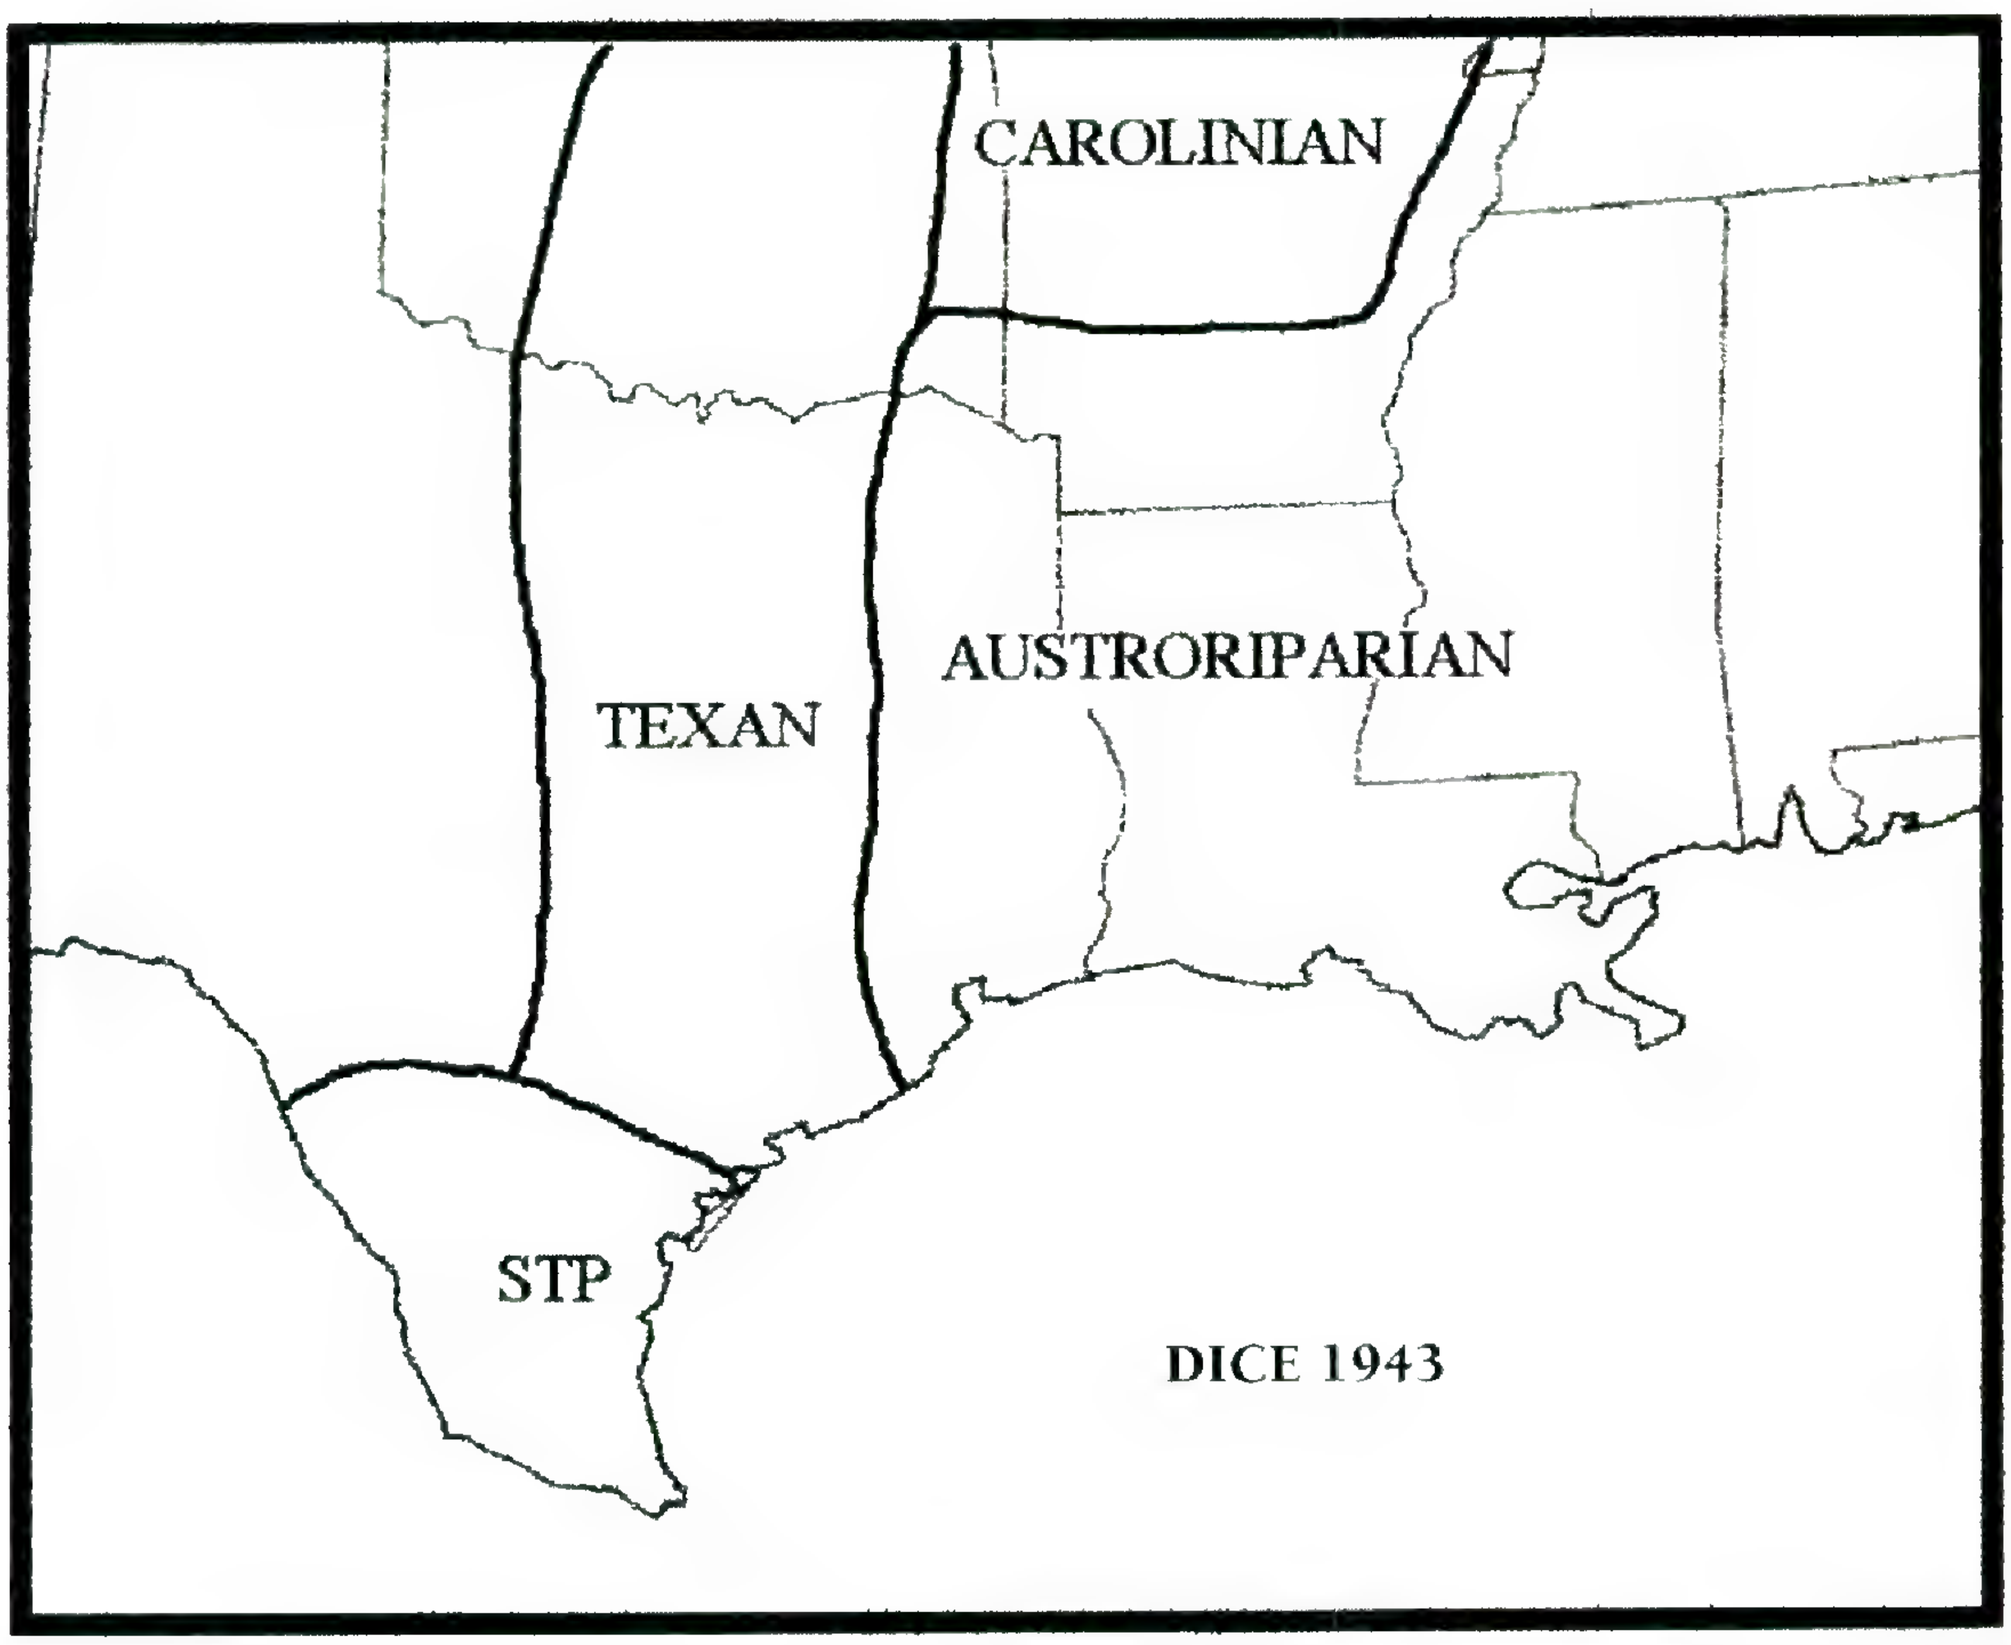

FIG. 11. Vegetation areas according to Dice 1943, 1968).

CONCLUSIONS

In summary, there has been relatively little evolution of the "ecoregion" maps of the WGCP over the 20th century. The patterns, but not the precise boundaries, found in the earliest maps are found in the later ones. The main questions appear to be whether or not to join the WGCP with the EGCP, whether or not to join the LLP region with the OPH region, and what to do with the POSa region? Should the latter be a part of a mega-region stretching from south Texas to Michigan? Should it be combined with the prairie region to the west, should it be kept separate from all other regions, or should it be cut in half and part of it put with the prairies and part with the OPH region? About half of the mappers recognize an LLP ecoregion, while the rest do not. It would appear that botanists who have constructed floras or distribution maps do not recognize a separate LLP ecoregion, presumably because the vegetational distinctiveness is either minor or virtually nonexistent (Correll & Johnston 1970; Gould 1975; Vines 1977; Nixon 1985; Hatch et al. 1990; Nixon & Kell 1993). Turner (1959) is the prime example of this. It is mainly ecologists who distinguish a separate LLP region.

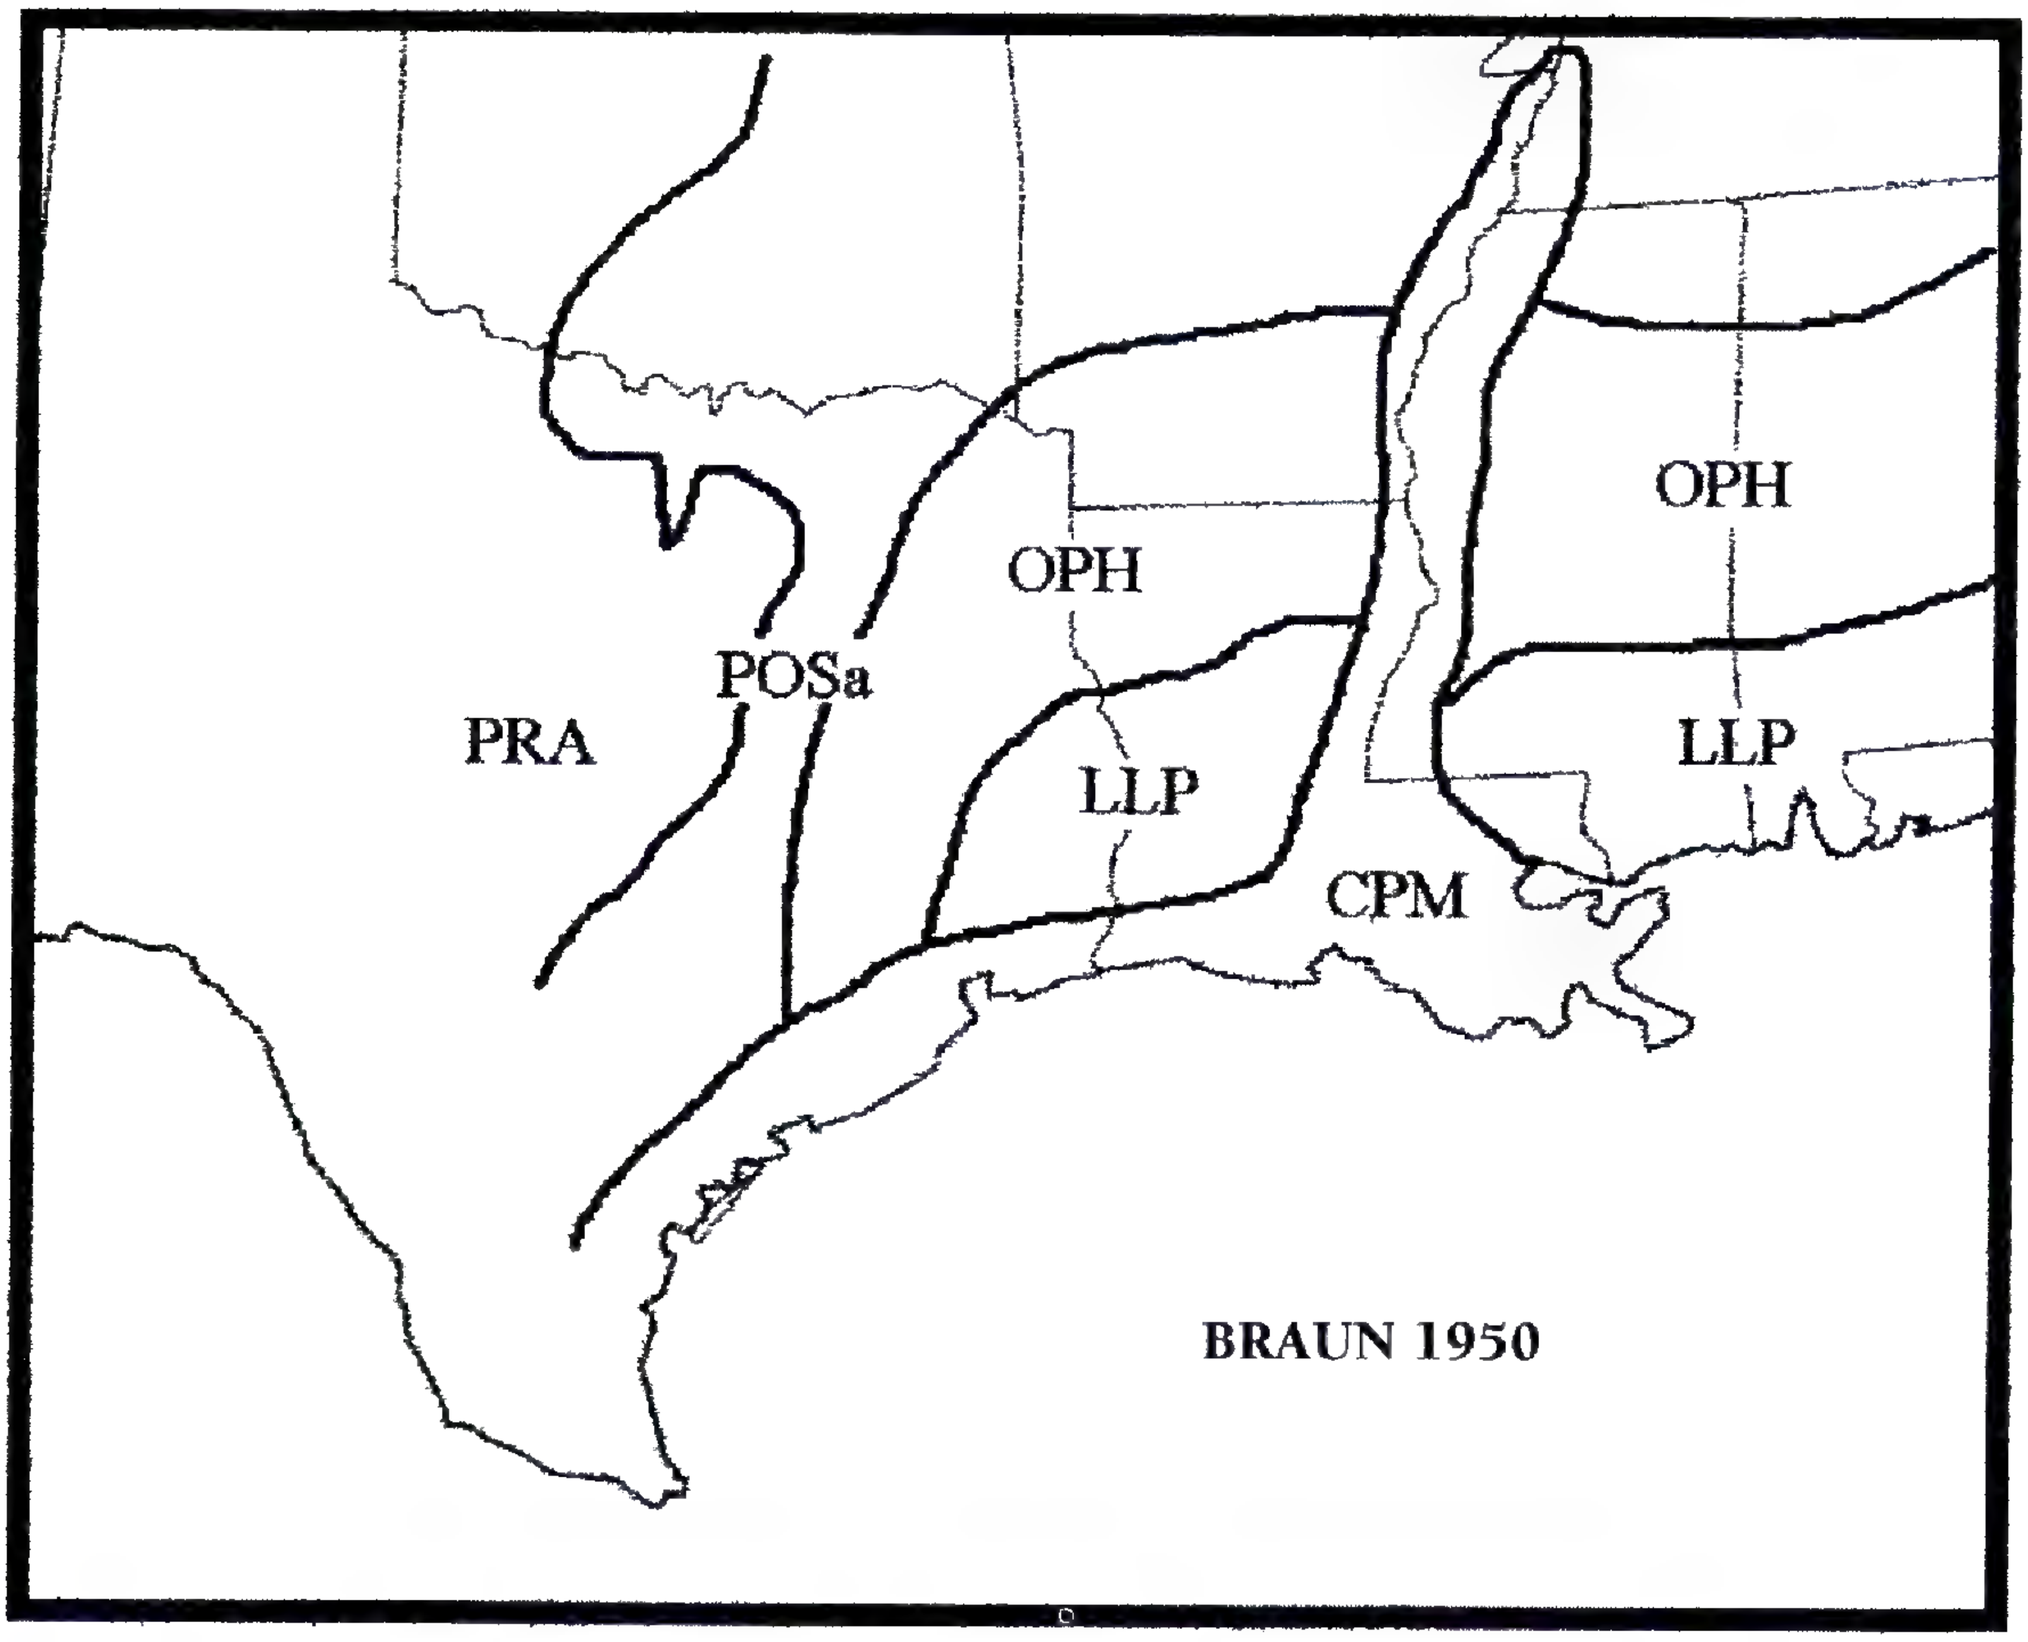

Fig. 12. Vegetation areas according to Braun (1950).

ACKNOWLEDGMENTS

Guy Nesom commented on several versions of the manuscript and brought B.L. Turner's ecoregion work to our attention. Billie Turner reviewed an earlier version of the manuscript and made many useful comments. L.M. Hardy aided with the maps.

THE JOHN D. FREEMAN HERBARIUM (AUA): A HISTORY AND CATALOGUE OF VASCULAR PLANT TYPE SPECIMENS

Curtis J. Hansen

John D. Freeman Herbarium
Biological Sciences Department
101 Life Sciences Building
Auburn University
Auburn, AL 36849, U.S.A.

ABSTRACT

The John D. Freeman Herbarium at Auburn University can trace its roots almost back to the foundation of the institution itself in 1856. By 1867 the campus boasted a natural history museum that housed botanical collections. This was most likely the first organized herbarium at Auburn University. Such notable former faculty as F.S. Earle, L.M. Underwood and especially P.H. Mell, Jr., surmounted early challenges, including a destructive fire in 1887, to establish and maintain a herbarium collection. By 1901, the herbarium housed over 40,000 specimens, including important collections from A.H. Curtiss, G.W. Carver, A.B. Langlois, and J. Darby. Tragically, the herbarium was again destroyed by fire in 1920. Despite this, AUA again emerged from the ashes to reestablish itself as an important state and regional herbarium. Growth at AUA from 1968–1995 was due to the efforts of the late John D. Freeman, who took the herbarium from obscurity to national recognition and quintupled the number of holdings during his tenure. The Freeman Herbarium now contains over 60,000 sheets and is one of the largest and most modern collections in Alabama. The herbarium currently houses 26 documented vascular plant type specimens that are catalogued.

RESUMEN

El Herbario John D. Freeman de la Universidad de Auburn puede rastrear sus raíces desde la fundación de la universidad en 1856. En 1867 la ciudad universitaria disfrutaba ya de un museo de historia natural que albergaba colecciones botánicas. Es probable que éste no fuese el primer herbario organizado que tuvo la Universidad de Auburn. Los primeros profesores destacables como F.S. Earle, L.M. Underwood, y especialmente, P.H. Mell, Jr., vencieron desafíos tempranos, incluso un incendio destructivo en 1887, que perjudicó el mantenimiento de la colección del herbario. En 1901, el herbario albergaba más de 40,000 especies, incluyendo colecciones importantes de A.H. Curtiss, G.W. Carver, A.B. Langlois, y J. Darby. Trágicamente, el herbario fue destruido una vez más por un incendio en 1920. A pesar de la segunda tragedia, el herbario volvió a surgir de las cenizas para restablecerse como uno de los herbarios más importantes del estado y de la región. El crecimiento del herbario desde los años 1968–1995, fue debido a los esfuerzos del ex-curador John D. Freeman, quien tomo el herbario desde sus penumbras hasta ser nacionalmente reconocido y quintuplicó el número de colecciones durante su periodo como curador. Actualmente el herbario John D. Freeman cuenta con más de 60,000 ejemplares y es uno de los herbarios más grandes y modernos del estado de Alabama. Hasta la fecha el herbario alberga 26 ejemplares tipo de plantas vasculares documentadas que están propiamente enumeradas y catalogadas.

SIDA 20(3): 1277–1287. 2003

HISTORY

The early history of the John D. Freeman Herbarium can be traced back almost to the foundation of Auburn University itself, and was directly affected by the challenges of establishing an institution of higher education in the late 1850s. Auburn University was originally chartered in 1856 as the East Alabama Male College (EAMC), a Methodist college that officially opened its doors to students in 1859 (Yeager & Stevenson 2000). Botany was the only life science course offered at the college and was first taught by John Darby, A.M., the "Julia Ann Hamiter" Professor of Natural Science (Davis 1992). Darby was a botanist, chemist, and author of one of the earliest floristic works to focus on the southern United States (Darby 1857). This work was intended as a botanical textbook for college and high school students throughout the South and was surely used in Darby's own curriculum, along with other botanical texts by Gray and Chapman. While there is no evidence that an official herbarium collection existed in 1859, Darby no doubt had a set of pressed and dried botanical specimens which he used for teaching botany and plant identification.

Botany continued to be taught until 1861 when EAMC was closed due to the Civil War, in which many of the faculty and students entered the Confederate service (Draughon 1954). The Old Main building, predecessor to current-day Samford Hall, served as a Confederate hospital from 1864–1866 (Yeager & Stevenson 2000). In 1866, the college reopened and Darby was again elected to teach botany (Minutes July 9, 1866). Darby was given emeritus status in 1869 but continued to be listed as a faculty member until 1871. In the 1867 catalogue of the EAMC it lists a "museum which is now being formed" as one of the assets and student recruiting points of the college. This museum housed plants, minerals, fossils, insects, mammals, and Indian relics, among other items. Darby was involved with the college museum and most likely organized the first herbarium collection at Auburn in the late 1860s.

A depressed, post-Civil War economy led to serious financial difficulties that plagued the college during the Reconstruction Period. In 1872, after much debate and considerable objection, the Board of Directors (later Board of Trustees) transferred the EAMC property and buildings to the state of Alabama to establish a land grant college under the provisions of the Morrill Land Grant Act passed by Congress in 1862 (Draughon 1954; Yeager & Stevenson 2000). This act, extended to former Confederate States after the Civil War and ratified by the Alabama Legislature in 1867, provided 30,000 acres of public land for each senator and representative of a state as an endowment to establish a college with the goal "to promote the liberal and practical education of the industrial classes in the several pursuits and professions of life" (Draughon 1954). In 1872, the college was officially named the Agricultural and Mechanical College of

Alabama (A & M College) and the herbarium became an integral part of Agricultural Experiment Station work.

Along with the change from church-college to state-college came changes in administration and some faculty members. In this turbulent time, J.B. Read was selected as the first Professor of Natural Sciences, which included the responsibility of teaching botany. However, his tenure was cut short, when after only eight months the Board of Directors reduced the number of faculty from eight to six, presumably for financial reasons. For the next three years the professorship of Natural Sciences was given to William C. Stubbs, a chemist. However Stubbs, who already taught chemistry, mineralogy and geology, probably did not take on the added responsibility of teaching botany. There are indications that in 1876 botany classes were taught by Professor of Agriculture and President of the young A & M College, Isaac T. Tichenor (botany classes were required by the School of Agriculture course of study according to the early and mid-1870s course catalogues [Yeager & Stevenson 2000]). In 1877, the Board of Trustees hired E.Q. Thornton as Professor of Natural Sciences, but his tenure lasted less than one year due to his unexpected death (Yeager & Stevenson 2000).

Finally, in 1878 the Trustees hired the talented Patrick H. Mell, Jr. to be Professor of Natural Science (Yeager & Stevenson 2000). Under Mell's direction and leadership the college museum holdings were greatly expanded through acquisition of specimens via purchases, exchanges with other institutions, and donations from private collectors and citizens. During Mell's tenure we find the first documentation of the actual size of the herbarium. Reporting for the 1881–1882 school year, Mell stated that the museum had increased in botanical collections from 266 to 1577 (Mell 1882). The following year he reported an increase of 442 botanical specimens for a grand total of 2019 (Mell 1883).

Tragically, in 1887, the herbarium was destroyed when Old Main caught fire and burned. While the number of collections destroyed isn't known, the herbarium was indeed important and growing under Mell's direction. He described his work and the condition of the herbarium prior to the fire as follows:

> "It was my pleasure to begin the preparation of this Botany of Alabama prior to 1887 but the destruction of the Museum by fire that year lost the Institution a valuable herbarium rich in plants collected from Alabama by Prof. Darby, Prof. Thornton, Prof. Stubbs and myself" (Annual Report 1896).

Despite the destruction of the herbarium, Mell published a list of cultivated grasses in Alabama which included the first attempt to list all the grasses that occurred in state (Mell 1889). Prior to the fire, Mell began compiling and writing the first flora of Alabama, to be issued in sections as they were completed (Mell 1896). He was finally able to publish one section of his flora but, unfortunately, no other sections were ever completed (Mell 1896). Incidentally, Charles

T. Mohr, who was concurrently writing his own Alabama flora, considered Mell an upstart in the business of writing the flora of Alabama, and felt threatened by his efforts (Davenport 1979).

Mell's talents were not limited to teaching botany and directing museum collections. Along with these responsibilities, he also served as the first Director of the Alabama Weather Service from 1884–1893, an agency that he created. He developed a system of flag signals used to relay weather conditions and forecasts around the state, a system that was soon adopted by the National Weather Service (Yeager & Stevenson 2000). Later, Mell declined to have his name submitted to President Grover Cleveland to become Chief of the U.S. Weather Bureau (see Mell Scrapbooks 1891–1906, Auburn Univ. Archives). In 1891, he was also appointed Director of the Alabama Experiment Station where he served until 1902 (Yeager & Stevenson 2000). In 1896, Mell was elected Chairman of the Section of Botany and Horticulture of the American Association of Agricultural Colleges and Experiment Stations (Anonymous 1899). After turning down other prestigious offers, including the presidency of Mercer University, Mell finally resigned from Auburn in 1902 to accept the presidency of Clemson College in South Carolina (Kerr 1985).

In late 1895, Lucien M. Underwood came to Auburn as a biologist and began working immediately on the "fungous flora of Alabama, since comparatively little is known of the extent and character of the rich cryptogamic flora of Alabama" (Annual Report 1896). Underwood departed after only one year but not before collecting a great deal and publishing a treatise on edible fungi (Underwood 1896).

Frank S. Earle succeeded Underwood and served as biologist and horticulturist. Earle finished the final preparations on Underwood's "fungous flora of Alabama" and in 1897 published their list of Alabama fungi with Underwood as lead author (Underwood & Earle 1897). This list enumerated over 1100 species of fungi known to occur in Alabama at the time. Also noted was the fact that the college at Auburn was the only institution in the state that maintained a course in botany. They also described some of the collectors and collections in the herbarium at that time (Underwood & Earle 1897). Earle later provided this list of fungi to Charles T. Mohr who included it in the fungi section of his monumental work on the flora of Alabama (Mohr 1901). Earle also studied and collected vascular plants from the unique habitats on and surrounding the metamorphic or granite outcrop regions of eastern Alabama (Earle 1902).

Earle provided excellent documentation of the growth and composition of the herbarium collections from 1896 to 1900. Indications are that Mell's administrative duties kept him away from the herbarium and that by the turn of the 20th century Earle was essentially managing the herbarium. On January 1, 1901, Earle reported the following numbers and composition of the herbarium (Annual Report 1901):

Flowering Plants, etc.	20,606
Fungi	16,950
Lichens	1,006
Mosses, etc	588
Algae	984
TOTAL	40,134

Considering that the herbarium burned in 1887 that was an impressive accumulation of specimens in 13 years.

Earle left Auburn in 1901 and was replaced by Edwin M. Wilcox, Professor of Botany, and self-described "Vegetable Physiologist and Pathologist" (Annual Report 1901). Wilcox was the department head and taught botany classes from 1902–1908. After he arrived, Wilcox immediately began preparing what amounted to the first plant atlas for the state of Alabama. He began a card index of all the plants, including a county map of the state pinpointing each collection location (Annual Report 1902). It is doubtful the project was ever completed because during his six-year tenure Wilcox only referred to the herbarium twice in his annual reports. Other than beginning the plant indexing project, Wilcox's only other reference to the herbarium was a request to get modern cases to hold and preserve the collections (Annual Report 1904). While Wilcox made some strides in maintaining the herbarium, no further reports documenting the size and growth of the herbarium exist after 1901. Most of Wilcox's time was spent working as a plant pathologist, not herbarium curator.

Francis E. Lloyd replaced Wilcox in 1908 as Professor of Botany. The herbarium was apparently poorly maintained and had fallen into disuse during Wilcox's tenure. In Lloyd's first report to the president he stated that, "Steps have been taken toward...the rehabilitation of the herbarium" which, he continues, "is of paramount importance for Experiment Station work as a source of information in matters pertaining to the flora of this section of the country" (Annual Report 1908). Despite Lloyd's emphasis on the importance and necessity of the herbarium, not much was accomplished during his first year. The next year, Lloyd again stressed the need to put the herbarium "into shape for use" (Annual Report 1909). Furthermore, Wilcox's 1904 request for modern herbarium cases must have gone unfulfilled because in 1909 Lloyd stated that the greatest need for the herbarium "is proper housing in the form of tightly constructed cases, since without these we cannot control the insect pests which are peculiarly bothersome here" (Annual Report 1909).

After 1909, little documentation is found relating to the herbarium. It is well known, however, that by 1910 the Botany Department (and herbarium), along with many other life science departments, had moved to a new building on campus. According to the 1910 bulletin, "A handsome and commodious building has been erected for the departments of (1) agriculture, (2) horticul-

ture, (3) botany, (4) entomology, and (5) animal husbandry" (Davis 1992). Furthermore, this building, named Comer Hall, was "thought to be superior or equal to any building in the south" (Yeager & Stevenson 2000). By 1918, the Botany Department occupied the western half of the third floor of Comer Hall. Incredibly, the herbarium was again completely destroyed by flames when a fire engulfed and gutted Comer Hall in October 1920! The total number of specimens lost in this fire is unknown, but by extrapolating from Earle's 1901 report of 40,134 total specimens, an estimate of greater than 50,000 specimens destroyed would be conservative.

The composition of the herbarium before the Comer Hall fire is fairly well documented, at least through the year 1900. The following is a list of some of the valuable collections known to have existed in the herbarium prior to the fire of 1920. Beyond simple documentation, this list serves only to sharpen the tragedy of the loss. First and foremost, the losses included important historical and scientific collections by G.F. Atkinson, C.F. Baker, G.W. Carver, J. Darby, J.F. Duggar, F.S. Earle, A.B. Langlois, P.H. Mell, Jr., W.C. Stubbs, E.Q. Thornton, L.M. Underwood, and an entire set of collections documenting A.H. Curtiss' work on the flora of Florida. Additionally, a large collection of Alabama grasses, an ample seed collection, and 500 exchange specimens from Liverpool, England were also consumed in the blaze. Finally, the loss of documentation for Mell's work on the Flora of Alabama, as well as many other research projects, was especially disappointing (Davis 1992). Other departments that were partially or completely destroyed included Agronomy, Plant Breeding, Soils, Plant Pathology, Horticulture, Animal Husbandry, Entomology, and the administrative offices (Annual Report 1921). The Comer Hall fire was a monumental loss in the history of the herbarium and Auburn University. However, unlike Comer Hall, which was rebuilt in two years, it took many decades to rebuild the herbarium.

While the herbarium was indeed reestablished, there is little information regarding its growth during the years following the fire. In the 1950s, the heirs of Elizabeth F. Andrews, a botanist and author, donated her personal collection of about 2500 plants to the herbarium which included collections by A.W. Chapman. This donation formed the nucleus for further rebuilding efforts. Donald E. Davis, Professor of Botany, came to Auburn in the late 1940s and served as herbarium curator for a time. Davis' students in plant taxonomy and weed science were required to submit specimens and thereby added many collections to the herbarium from 1947–1968 (Davis 1992). Other taxonomists in the botany department during the 1950s and 1960s included Edward T. Browne, Jr. and Alfred C. Koelling (Don Davis, pers. comm.). Browne came to Auburn in 1956 and was herbarium curator until about 1960. The herbarium grew very little during his short tenure, but herbarium records do indicate there was an exchange agreement with the University of Georgia. Browne himself only added about two dozen of his personal collections to the herbarium. Later, Koelling served

as herbarium curator from 1964–1967. In efforts to increase herbarium holdings, Koelling initiated a number of exchanges with other institutions and also added over 750 of his own collections. Herbarium growth from 1922 to 1968 was modest, but by 1968 the herbarium contained a total of 11,300 sheets (Davis 1992).

Herbarium growth from 1968–1995 was due to the efforts of the late John D. Freeman, who emphasized the importance of fieldwork and collecting, and that the herbarium was an essential and valuable botanical research tool. He initiated exchange programs with many institutions and was active in loaning specimens out to various researchers. Freeman directed several graduate student research studies that helped document the flora and assess plant distributions in critical areas throughout the state. These types of studies led to active collecting efforts and, in turn, added greatly to the herbarium holdings. Undergraduate students who took Freeman's systematic botany courses can testify to the emphasis he placed on collecting. His students were required to turn in large collections of 150–200 plants — pressed, identified and labeled — at the conclusion of the course. That amount of collecting kept exchange programs bolstered and greatly enlarged the herbarium holdings. In 1974, Freeman summarized the growth of the herbarium during his first five years at Auburn as follows (Freeman 1974):

Year	Specimens mounted and shelved
1969	3,357
1970	3,737
1971	3,640
1972	2,100
1973	1,420
Total	14,254
Cumulative through 1968	11,300
Present holdings	25,554

Over his career, Freeman took the herbarium from relative obscurity to national recognition. In 1974, the Advisory Committee for Systematic Resources in Botany (1974) selected the Auburn University Herbarium as a National Resource Collection, a collection considered vital for continued science support and research. This designation was given to only 105 (out of a total of 1127) institutions nationwide. Freeman's personal research interests likewise garnered national attention as he focused on the genus *Trillium*. He collected *Trillium* from all across the United States and Japan, naming seven new species including the federally listed southeastern endemic *Trillium reliquum*.

Prior to his death, Freeman helped negotiate the acquisition of the herbarium collection at St. Bernard College (SB) in Cullman County, Alabama. This

invaluable, historic collection of about 5000 sheets was the personal herbarium of Wolfgang Wolf, a prolific botanist in the early 20th century and lay brother of the Order of Saint Benedict. This collection contains not only Alabama plants but also many collections from around the eastern United States and Europe. This acquisition added greatly to the holdings of the Freeman Herbarium and pushed the number of total collections to over 60,000. Ultimately, Freeman increased the number of mounted specimens five-fold in 27 years. In January 1998, the Board of Trustees, in recognition of his enormous botanical contributions, unanimously passed a resolution officially naming the Auburn University Herbarium in honor of Dr. John D. Freeman.

With no permanent curator in place after 1995, activity at the Freeman Herbarium dropped dramatically. For the next three years Jerome Ward, a visiting assistant professor, supervised herbarium activity on a part-time basis and, with the help of students, began the long process of organizing and incorporating the St. Bernard collection.

From 1998 to 2002, Cynthia M. Morton held the post of plant taxonomist and director of the Freeman Herbarium, and in 1999 the author was hired as curator. Under Morton's direction the Freeman Herbarium was brought back to full activity with the resumption of many exchange agreements and increased loan activity. The collections were refoldered using archival quality genus covers, updated taxonomically, and organized geographically. Many misfiled collections were found and duplicate collections removed, which greatly relieved limited cabinet space. Another major emphasis during this time was to have the label information from each specimen entered into a computer database. With the help of students and support from the State Lands Division of the Alabama Natural Heritage Program, this project was completed in 2002. The database is maintained as new specimens are accessioned and added to the collection and is available via the World Wide Web at http://www.auburn.edu/herbarium. The effort to database the herbarium collection has led to the publication of a checklist of Alabama plants compiled from the combined information of the Freeman Herbarium and University of Alabama Herbarium (UNA) (Morton et al. 2002).

The Freeman Herbarium is now one of the largest collections in Alabama and is a vital resource for various natural science departments at Auburn University including the Agricultural Experiment Station, Biological Sciences, Entomology & Plant Pathology, Forestry, Horticulture, Pharmacy, Veterinary Medicine, and Wildlife. The Freeman Herbarium is used throughout the region by other colleges, universities, private companies, and government agencies, and serves as the state herbarium (Alabama Code §1-2-12). The collection houses valuable historic specimens that date to the late 19th and early 20th centuries, including many by E.F. Andrews, A.W. Chapman, and W. Wolf with the earliest collections dating to the 1840s. More recent contributors who have added im-

portant collections to the Freeman Herbarium include V.E. Crouch, A.R. Diamond, J.D. Freeman, S.C. Gunn, R. Kral, H.D. Moore, D.W. Rutland, A.H. Sessler and J.W. Short. While it is richest in specimens from Alabama and the southern United States, the Freeman Herbarium also contains collections from around the country and from many continents in the world. Growth and diversification of the Freeman Herbarium are continuing through open gift and exchange programs and fieldwork.

TYPE SPECIMENS

Currently, the Freeman Herbarium contains over 60,000 mounted vascular plants, of which 26 are documented as types either through citation in original literature or as annotated by a later researcher. This list includes 2 holotypes, 23 isotypes, 1 isoneotype and is arranged alphabetically by family, then by genus. The majority of type specimens are found in Trilliaceae (8) and Asteraceae (7). The reference citation, location (restricted to country, state and county, or equivalent), date, collector, collector number, AUA accession number, and the holotype location, if known, is documented for each specimen.

CATALOGUE OF TYPE SPECIMENS

ARISTOLOCHIACEAE

Hexastylis shuttleworthii (Britten & Baker) Small var. **harperi** Gaddy, ISOTYPE. Sida 12:54. 1987. USA. Georgia. Madison Co.: 9 May 1986, *Gaddy s.n.* AUA 60732. (HOLOTYPE: CLEMS).

ASTERACEAE

Coreopsis grandiflora Hogg ex Sweet var. **inclinata** J. Allison, ISOTYPE. Castanea 66:162. 2001. USA. ALABAMA. BIBB CO.: 15 Jul 1999, *Allison 12086*. AUA 61466. (HOLOTYPE: US).

Erigeron strigosus Muhl. ex Willd. var. **dolomitica** J. Allison, ISOTYPE. Castanea 66:169. 2001. USA. ALABAMA. BIBB CO.: 10 Jun 2000, *Allison 12396*. AUA 61464. (HOLOTYPE: NY).

Liatris ×freemaniana J. Allison, HOLOTYPE. Castanea 66:179. 2001. USA. ALABAMA. BIBB CO.: 18 Jul 1993, *Allison and Stevens 7804*. AUA 61463.

Liatris ×macdanieliana J. Allison, ISOTYPE. Castanea 66:180. 2001. USA. ALABAMA. BIBB CO.: 20 Aug 1994, *Allison 8559*. AUA 61462. (HOLOTYPE: US).

Liatris oligocephala J. Allison, ISOTYPE. Castanea 66:175. 2001. USA. ALABAMA. BIBB CO.: 18 Jul 1993, *Allison and Stevens 7802*. AUA 61461. (HOLOTYPE: GH).

Silphium glutinosum J. Allison, ISOTYPE. Castanea 66:183. 2001. USA. ALABAMA. BIBB CO.: 19 Aug 2000, *Allison 12503*. AUA 61459. (HOLOTYPE: GH).

Silphium perplexum J. Allison, ISOTYPE. Castanea 66:188. 2001. USA. ALABAMA. DALLAS CO.: 18 Aug 1999, *Allison 12153*. AUA 61458. (HOLOTYPE: GH).

BORAGINACEAE

Onosmodium decipiens J. Allison, ISOTYPE. Castanea 66:180. 2001. USA. ALABAMA. BIBB CO.: 1 Nov 1993, *Allison and Stevens 8139*. AUA 61460. (HOLOTYPE: NY).

CYPERACEAE

Carex cumberlandensis Naczi, Kral, & Bryson, ISOTYPE. Sida 19:994. 2001. USA. ALABAMA. WINSTON CO.: 4 May 1991, *Naczi 2868*. AUA 62540. (HOLOTYPE: DOV).

Fimbristylis argillicola Kral, ISOTYPE. Sida 4:128. 1971. MEXICO. MICHOACAN. 18 Aug 1965, *Kral 25509*. AUA 16998. (HOLOTYPE: MICH).

FABACEAE

Dalea cahaba J. Allison, ISOTYPE. Castanea 66:166. 2001. USA. ALABAMA. BIBB CO.: 1 May 1994, *Allison and Stevens 8236*. AUA 61465. (HOLOTYPE: NY).

LAMIACEAE

Scutellaria montana Chapman, ISOTYPE [det. by Robert Kral 1979]. Bot. Gaz. 3:11. 1878. USA. GEORGIA. FLOYD CO.: no date, *Chapman s.n.* AUA 4168.

PORTULACACEAE

Talinum mengesii W. Wolf, HOLOTYPE [det. by Kenneth J. Wurdack 1988]. Amer. Mid. Naturalist 6:153. 1920. USA. ALABAMA. CULLMAN CO.: 9 Aug 1919, *Wolf s.n.* AUA 60731.

RANUNCULACEAE

Clematis morefieldii Kral, ISOTYPE. Annals Missouri Bot. Gard. 74:665. 1987. USA. ALABAMA. MADISON CO.: 17 Jun 1983, *Kral 70176.* AUA 45730. (HOLOTYPE: MO).

SCROPHULARIACEAE

Castilleja kraliana J. Allison, ISOTYPE. Castanea 66:159. 2001. USA. ALABAMA. BIBB CO.: 15 Apr 1998, *Allison 10466.* AUA 61467. (HOLOTYPE: NY).

TRILLIACEAE

Trillium albidum J.D. Freeman, ISOTYPE. Brittonia 27:48. 1975. USA. OREGON. JOSEPHINE CO.: 9 May 1967, *Freeman 596 with Freeman.* AUA 56829. (HOLOTYPE: GH).

Trillium channellii I. Fukuda, J.D. Freeman & M. Itou, ISOTYPE. Novon 6:164. 1996. JAPAN. HOKKAIDO. KUSHIRO DIST.: 21 May 1994, *Fukuda and Itou s.n.* AUA 57091. (HOLOTYPE: MAK).

Trillium cuneatum Raf., ISONEOTYPE. Brittonia 27:34. 1975. USA. NORTH CAROLINA. BUNCOMBE CO.: 13 Apr 1966, *Kral 26254.* AUA 21765. (NEOTYPE: GH).

Trillium decipiens J.D. Freeman, SOTYPE. Brittonia 27:17. 1975. USA. GEORGIA. EARLY CO.: 28 Mar 1968, *Freeman 615 with Murrell, Ihara & Ihara.* AUA 56759. (HOLOTYPE: GH).

Trillium foetidissimum J.D. Freeman, SOTYPE. Brittonia 27:31. 1975. USA. MISSISSIPPI. ADAMS CO.: 30 Mar 1967, *Freeman 535 with Murrell & Ihara.* AUA 16713. (HOLOTYPE: GH).

Trillium gracile J.D. Freeman, SOTYPE. Sida 3:289. 1969. USA. TEXAS. SABINE CO.: 1 Apr 1966, *Samejima 1039 with Freeman & Channell.* AUA 56878. (HOLOTYPE: GH).

Trillium kurabayashii J.D. Freeman, ISOTYPE. Brittonia 27:56. 1975. USA. CALIFORNIA. DEL NORTE CO.: 8 May 1967, *Freeman 594 with Freeman.* AUA 56822. (HOLOTYPE: GH).

Trillium maculatum Raf. f. **simulans** J.D. Freeman, ISOTYPE. Brittonia 27:29. 1975. USA. SOUTH CAROLINA. DORCHESTER CO.: 10 Apr 1966, *Freeman 451a with Freeman.* AUA 56864. (HOLOTYPE: VDB).

Trillium reliquum J.D. Freeman, ISOTYPE. Brittonia 27:21. 1975. USA. GEORGIA. RICHMOND CO.: 20 Mar 1968, *Freeman 625 with Murrell, Ihara & Ihara.* AUA 56862. (HOLOTYPE: GH).

XYRIDACEAE

Xyris tennesseensis Kral, ISOTYPE. Rhodora 80:444. 1978. USA. TENNESSEE. LEWIS CO.: 26 Aug 1969, *Kral 36370.* AUA 32229. (HOLOTYPE: US).

ACKNOWLEDGMENTS

I am grateful to Don Davis for sharing early memories of the Freeman Herbarium and Botany Department at Auburn University, and to the staff of the Special Collections & Archives Department at the Auburn University Library for their helpful assistance in many hours spent researching records. I thank Terry Rodriguez of the Office of Communications at the Alabama Agricultural Experiment Station for tracking down original copies of some very old extension bulletins and then sharing in the excitement of discovery. Roland Dute provided helpful comments on an earlier draft of this manuscript. Critical reviews by Larry Davenport and Robert Kral improved this paper. I thank Glenda Gil for her Spanish translation of the abstract.

ABSTRACT

Additions to the vascular floras of four states are reported herein: Colorado (*Calibrachoa parviflora*, *Chamaesyce prostrata*, *Gleditsia triacanthos*, *Oenothera engelmannii*, *Oenothera laciniata*, *Trianthema portulacastrum*, and *Veronica persica*); Iowa (*Deschampsia danthonioides*); Kansas (*Alternanthera caracasana*, *Carex albicans* var. *australis*, *Carex swanii*, *Carum carvi*, *Catharanthus roseus*, *Cyperus diandrus*, *Dichanthelium dichotomum* subsp. *dichotomum*, *Dichanthelium polyanthes*, ×*Elyhordeum montanense*, *Erigeron canus*, *Geranium dissectum*, *Geranium molle*, *Hibiscus syriacus*, *Phyllanthus urinaria* subsp. *urinaria*, *Pyrus calleryana*, *Sagina apetala*, *Sedum sarmentosum*, *Silphium radula*, and *Tridens flavus* var. *chapmanii*); and Oklahoma (*Epilobium leptophyllum*).

RESUMEN

Se hacen adiciones a la flora vascular de cuatro estados: Colorado (*Calibrachoa parviflora*, *Chamaesyce prostrata*, *Gleditsia triacanthos*, *Oenothera engelmannii*, *Oenothera laciniata*, *Trianthema portulacastrum*, y *Veronica persica*); Iowa (*Deschampsia danthonioides*); Kansas (*Alternanthera caracasana*, *Carex albicans* var. *australis*, *Carex swanii*, *Carum carvi*, *Catharanthus roseus*, *Cyperus diandrus*, *Dichanthelium dichotomum* subsp. *dichotomum*, *Dichanthelium polyanthes*, ×*Elyhordeum montanense*, *Erigeron canus*, *Geranium dissectum*, *Geranium molle*, *Hibiscus syriacus*, *Phyllanthus urinaria* subsp. *urinaria*, *Pyrus calleryana*, *Sagina apetala*, *Sedum sarmentosum*, *Silphium radula*, y *Tridens flavus* var. *chapmanii*); y Oklahoma (*Epilobium leptophyllum*).

Continuing field and herbarium studies in the grassland biome of central North America have produced additional records of vascular plants previously undocumented in parts of the region. Herein we report 28 new state records for vascular plants in Colorado (7), Iowa (1), Kansas (19), and Oklahoma (1). Thirteen of these reports are considered to be native occurrences in the region; fifteen (marked with an asterisk) are considered the results of recent introduc-

SIDA 20(3): 1289–1297. 2003

tions. These reports update the distribution data contained in *Atlas of the Flora of the Great Plains* (Great Plains Flora Association 1977) and *Flora of the Great Plains* (Great Plains Flora Association 1991). All voucher specimens are deposited in the R. L. McGregor Herbarium (KANU), University of Kansas, unless otherwise indicated.

***Alternanthera caracasana** Kunth (Amaranthaceae). Native to South and Central America, mat chaff-flower has been reported from throughout the southern U.S. (Kartesz & Meacham 1999). Previous reports record this species from the panhandle of Texas and Oklahoma (Great Plains Flora Association 1991). A single specimen confirms its presence in Kansas.

Voucher specimen: **KANSAS. Douglas Co.:** Lawrence, University of Kansas Campus, T12S, R20E, sec 36, SW 1/4, SE 1/4, near 38°57'29"N, 95°14'54"W, elev 305 m, weedy plantings and sidewalk cracks on campus, 30 Aug 2002, *Morse 8534*.

***Calibrachoa parviflora** (Juss.) D'Arcy (Solanaceae). This prostrate annual occurs throughout the southern U.S. and tropical America and is probably a recent introduction into the Great Plains. Freeman et al. (1998) reported it from central Kansas. Two populations were discovered in eastern Colorado in 2000, both along the shorelines of reservoirs.

Voucher specimens: **COLORADO. Bent Co.:** Las Animas, 12 mi N, Adobe Creek Reservoir State Wildlife Area, SE side of Adobe Creek Reservoir, T21S, R52W, sec 4, E1/2, SE1/4, elev 4,140 ft, level, grazed, shortgrass prairie and muddy to sandy shoreline, 26 Jun 2000, *Freeman 15345 & Morse*. **Kiowa Co.:** Eads, 10 mi S, 4.5 mi E, Neenoshe Reservoir, S side, T20S, R47W, sec 9, SW 1/4, SW 1/4 & sec 16, N 1/4, elev 3,930 ft, open, sandy to muddy shoreline and adjacent, wooded perimeter of reservoir, 20 Aug 2000, *Freeman 15982 & Morse*.

Carex albicans Willd. ex Spreng. var. **australis** (L.H. Bailey) Rettig (Cyperaceae). Rettig (1990) recognized three varieties of *C. albicans*. Variety *albicans* occurs in the Great Plains from eastern Nebraska south through eastern Kansas and into central Oklahoma (Rolfsmeier & Wilson 1997; Taylor & Taylor 1994; Yatskievych 1999). Recently, a population of approximately 100 individuals clearly referable to var. *australis* was discovered in southeast Kansas in a sandy, oak woodland. The nearest documented populations in Arkansas (Hyatt 1998) and Missouri (Yatskievych 1999) are more than 250 km away.

Voucher specimens: **KANSAS. Neosho Co.:** Thayer, 0.5 mi W, Thayer City Lake, N side, 37°29'01"N, 95°29'13"W, post oak-blackjack oak woodland on sandstone, gentle S facing slope with a few mesic ravines, 17 Apr 2001, *Freeman 16776*.; Thayer, 0.5 mi W, N side Thayer City Lake, T29S, R18E, sec 31, NW 1/4, NW 1/4, elev 305 m, mowed parkland, picnic area, and open blackjack oak-post oak forest, soil sandy, 23 Apr 2001, *Morse 5486 & W. Michener*.

Carex swanii (Fernald) Mack. (Cyperaceae). *Carex swanii* is broadly distributed throughout the eastern U.S. and southeastern Canada. A small population recently discovered in eastern Kansas extends the range of this species by more than 300 km from the nearest known stations in central Arkansas (Hyatt 1998) and southeastern Missouri (Yatskievych 1999).

Voucher specimen: **KANSAS. Douglas Co.:** Junction of US Hwy 56 and Co Rd 1055 in Baldwin City, 3 mi N, 2.25 mi E, T14S, R20E, sec 13, S 1/2, SW 1/4, near 38°49'30"N, 95°08'30"W, elev ca 290 m, open, black-post-blackjack oak forest and upland tallgrass prairie on N- and W-facing slopes, surfacing sandstone, sandy soil, 27 Jun 2002, *Morse* 8383. [Additional voucher at MICH]

***Carum carvi** L. (Apiaceae). Caraway is a Eurasian biennial that has become established sporadically in waste places in the northern Great Plains (Great Plains Flora Association 1991). The species now is added to the Kansas flora based on a population recently discovered in the extreme eastern part of the state.

Voucher specimen: **KANSAS. Miami Co.:** Somerset, 1 mi E, T17S, R24E, sec 3, SW 1/4, NW 1/4, near 38°36'00"N, 94°45'00"W, elev 275 m, weedy floodplain forest and rocky gravel bars along S side South Wea Creek, 5 Oct 2000, *Morse 5186.*

***Catharanthus roseus** (L.) G. Don (Apocynaceae). A native of the Old World tropics, rosy periwinkle has been planted extensively as an ornamental in the U.S. Kartesz and Meacham (1999) mapped records from scattered states in the southern U.S. Recent observations and a single collection confirm the presence of *C. roseus* as an adventive species in Kansas.

Voucher specimen: **KANSAS. Douglas Co.:** Lawrence, University of Kansas Campus, T12S, R20E, sec 36, SW 1/4, SE 1/4, near 38°57'29"N, 95°14'54"W, elev 305 m, weedy plantings and sidewalk cracks on campus, 30 Aug 2002, *Morse* 8533.

Chamaesyce prostrata (Aiton) Small (Euphorbiaceae). Prostrate mat-spurge is a common annual in the southern half of the Great Plains. Kansas and Nebraska records occur westward to the Colorado border (Great Plains Flora Association 1977), but there are no records for that state. It now may be included based on a single collection from extreme east-central Colorado.

Voucher specimen: **COLORADO. Kit Carson Co.:** Burlington, 3 mi E along US 24, T8S, R43W, sec 35, NW 1/4, NW 1/4, elev 4,010 ft, disturbed, open roadside just S of I-70 overpass, soil silty, 18 Aug 2000, *Freeman 15764 & Morse.*

Cyperus diandrus Torr. (Cyperaceae). *Cyperus diandrus* is confined to the extreme eastern Great Plains (Great Plains Flora Association 1977) except in Nebraska, where it is fairly widespread (Rolfsmeier 1995). In far western Missouri, Yatskievych (1999) mapped records from Jackson and Dade counties. Previous reports of the species in Kansas (Gates 1940) were based on misidentified specimens of the superficially similar *C. bipartitus* Torr. The species now may be included in the Kansas flora based on an overlooked specimen collected 40 years ago. Several recent attempts to relocate this population have been unsuccessful.

Voucher specimen: **KANSAS. Atchison Co.:** Mouth of Independence Creek, 28 Jul 1961, *Blocker 789* [KSC].

***Deschampsia danthonioides** (Trin.) Munro ex Benth. (Poaceae). This tiny annual, native to western North America and South America (Cronquist et al. 1977),

has been reported as adventive in Ohio, New York, and Maine (Kartesz & Meacham 1999). The first record from Iowa, where it apparently was a contaminant in grass seed, is reported here. The site has been revisited several times, but there is no evidence that plants have persisted.

Voucher specimen: IOWA. **Bremer Co.:** Waverly, S edge of town, T91N, R14W, sec 10, SE 1/4, SE 1/4, 42°42'03"N, 92°28'34"W, elev 990 ft, small area of reseeded lawn on W side of US 218 at 2416 4th Street SW, exposed, loamy soil, 6 Jul 2001, *Freeman 17518*.

Dichanthelium dichotomum (L.) Gould subsp. **dichotomum** (Poaceae). *Dichanthelium dicotomum* is known from several counties in extreme western Missouri (Yatskievych 1999), but has not been reported from Kansas. Recent examination of specimens at KANU revealed a single specimen misidentified as *D. acuminatum* (Sw.) Gould & Clark var. *fasciculatum* (Torr.) Freckmann, which represents the first verified record for the state.

Voucher specimen: **KANSAS. Franklin Co.:** 1 mi E, 3 mi S Homewood, ridge of N-facing cliffs above small stream on W side of road, plants in sandy soil, dry, 20 Aug 1976, *Brooks 12447*.

Dichanthelium polyanthes (Schult.) Mohlenbr. (Poaceae). Kartesz and Meacham (1999) mapped records of this taxon, as *D. sphaerocarpon* (Ell.) Gould var. *isophyllum* (Scribn.) Angelo, from throughout the eastern U.S., westward to Missouri, Oklahoma, and Texas. For its part, *D. sphaerocarpon* is common in eastern Kansas, but no attempt has been made to distinguish the other members of the complex to which that species belongs. Recent examination of Kansas specimens identified as *D. sphaerocarpon* at KANU revealed a single specimen of *D. polyanthes*, which represents the first verified record for the state.

Voucher specimen: **KANSAS. Cherokee Co.:** 3.5 mi E Crestline, moist open woodland, 22 Jul 1982, *McGregor 33433*.

×**Elyhordeum montanense** (Scribn.) Bowden (Poaceae). This naturally occurring hybrid between *Elymus virginicus* L. and *Hordeum jubatum* L. subsp. *jubatum* has been reported from nearly a dozen states and provinces in the U.S. and Canada (Kartesz & Meacham 1999). A recently redetermined specimen at KANU is the first record for Kansas.

Voucher specimen: **KANSAS. Republic Co.:** T4S, R2W, sec 28, elev 1,380 ft, silty clay loam, 25 Aug 1995, *Elliott 1162*.

Epilobium leptophyllum Raf. (Onagraceae). *Epilobium leptophyllum* is an herbaceous perennial found in fens, marshes, and seeps throughout the northern and central Great Plains (Great Plains Flora Association 1991), occurring southward to Meade County, Kansas (Great Plains Flora Association 1977). A small population discovered in extreme western Oklahoma, on a seepy, open slope near the Ogallala-Doxey contact is 180 km south-southeast of the southernmost Kansas population.

Voucher specimen: OKLAHOMA. **Roger Mills Co.:** Cheyenne, 3.5 mi S, 4 mi W, Thurmond Ranch, T12N, R24W, sec 4, NE 1/4, 35°32'51"N, 99°44'27"W, elev 2,260-2,300 ft, gently rolling sandsage prai-

rie and mixed-grass prairie with abundant oak mottes, small pond at upper reaches of Sergeant Major Creek, Tertiary Ogallala Formation, 3 Oct 2001, *Freeman 18359 & Morse*.

Erigeron canus A. Gray (Asteraceae). Hoary fleabane grows on rocky, shortgrass prairies in the High Plains from South Dakota and Wyoming, south to New Mexico. Examination of specimens at KANU revealed plants misidentified as *E. pumilus* Nutt., including six from extreme northwestern Kansas, which represent the first verified records of the species from the state.

Voucher specimens: **KANSAS. Cheyenne Co.:** St. Francis, 12 mi N, 12 mi W, upland prairie pasture, top of sandrock ledge, thin soil, 9 Jun 1967, *Stephens 11449 & Brooks*; St. Francis, 12 mi N, 12 mi W, high prairie, hilltop, dry, rocky, gravel soil, 4 Jun 1969, *Stephens 31383 & Brooks*; St. Francis, 12 mi N, 12 mi W, top of rocky, prairie hill, 5 Jun 1981, *Stephens 90302*. **Rawlins Co.:** Atwood, 8 mi SW, dry rocky prairie ridge, 27 Jun 1954, *McGregor 9449*; Beardsley, 3.5 mi S, gravelly prairie hillside, 22 May 1975, *Brooks 9662*; McDonald, ca 11 mi S, 6 mi E, T5S, R35W, sec 7, E $^1/_2$ & sec 8, W $^1/_2$, elev 3,200–3,300 ft, N-S trending canyon that joins Beaver Creek to the N, grazed, upland, shortgrass prairie, extensive outcrops of Ogallala Formation in the area, 30 May 1991, *Freeman & Brooks 3516*.

***Geranium dissectum** L. (Geraniaceae). *Geranium dissectum* is a native of Europe now established throughout the eastern and western U.S. and Canada (Gleason & Cronquist 1991; Kartesz & Meacham 1999). A single record confirms its presence in Kansas.

Voucher specimen: **KANSAS. Labette Co.:** Parsons, E side, open grassy area by Labette Creek along US 160, 7 May 1998, *Holland 9312*.

***Geranium molle** L. (Geraniaceae). Dove-foot crane's-bill is a native of Europe and western Asia (Gleason and Cronquist 1991). It is now a widespread weed in the eastern and western U.S. (Kartesz & Meacham 1999), but records from the Great Plains are rare. A specimen recently was found at KANU among 80 specimens of *G. pusillum* L. and is the only record for Kansas.

Voucher specimen: **KANSAS. Wilson Co.:** Fredonia, 6 mi N, 4 mi W, T28S, R14E, sec 7, SE $^1/_4$, SE $^1/_4$, near old farm house in scrub oak woods, 12 Jun 1995, *McGregor 41124*.

***Gleditsia triacanthos** L. (Fabaceae). Common honey-locust is native to the eastern U.S., apparently occurring naturally westward to central Nebraska and Kansas (Great Plains Flora Association 1977, 1991). However, its native range in the Great Plains has been obscured by its long history of cultivation as a shade tree and in windbreaks and fencerows. The species was not included in the Colorado flora by Weber and Wittmann (1992), but KANU now has two specimens of this tree from the eastern part of the state. Both records are presumably the result of introductions in recent decades.

Voucher specimens: **COLORADO. Kit Carson Co.:** Flagler, 3.5 mi E, Flagler State Wildlife Area, elev 4,710–4,770 ft, rocky, shortgrass prairie on the W side of Flagler Lake, 14 May 2000, *Freeman 14319*. **Yuma Co.:** Beecher Island, 3.5 mi S, dry prairie hillside pasture, 18 Jun 1966, *Stephens 4871*.

***Hibiscus syriacus** L. (Malvaceae). A native of east Asia, Rose-of-Sharon is widely planted in the U.S., occasionally escaping from cultivation (Gleason & Cronquist 1991). Kartesz and Meacham (1999) mapped records from throughout the east-

ern U.S. and in Utah. Steyermark (1977) reported the species as rarely escaping in Missouri. In the Great Plains, *H. syriacus* often persists after cultivation, but escaped plants have not been recorded in our region. A plant discovered in eastern Kansas appears not to have been planted.

Voucher specimen: **KANSAS. Douglas Co.:** Lawrence, T13S, R19E, sec 12, NW 1/4, NW 1/4, NE 1/4, 38°56'39"N, 95°15'01"W, elev 255 m, weedy forest edge along Naismith Creek, 7 Sep 2001, *Morse* 7322.

Oenothera engelmannii (Small) Munz (Onagraceae). Harrington (1954) included Engelmann's evening-primrose in his flora of Colorado; however, Weber and Wittmann (1992) excluded it because the voucher for the report was misidentified. A specimen at KANU confirms that the species occurs in Colorado.

Voucher specimen: **COLORADO. Baca Co.:** Ca 8 mi W of Elkhart, KS, on the W side of Morton County Rd B along the KS-CO border, S of the Cimarron River, T35S, R41W, sec 10, NE 1/4, SE 1/4, elev 3,610-3,620 ft, grazed, upland, rolling, sandsage prairie, soil sandy, 2 Jun 1989, *Freeman 3023*.

Oenothera laciniata Hill (Onagraceae). Weber and Wittmann (1992) stated that cut-leaf evening-primrose must occur in eastern Colorado based on nearby collections from Kansas, Nebraska, and Oklahoma. This species may be added to the Colorado list based on a collection from the extreme southeast part of that state.

Voucher specimen: **COLORADO. Baca Co.:** Ca 8 mi W of Elkhart, KS, on the W side of Morton County Rd B along the KS-CO border, S of the Cimarron River, T35S, R41W, sec 10, NE 1/4, SE 1/4, elev 3,610-3,620 ft, grazed, upland, rolling, sandsage prairie, soil sandy, 2 Jun 1989, *Freeman 3024*.

***Phyllanthus urinaria** L. subsp. **urinaria** (Euphorbiaceae). A native of tropical east Asia, peewater leaf-flower was first documented in North America in 1944 (Webster 1970). The species is now established in the southeastern U.S. and Illinois (Kartesz & Meacham 1999), where it is probably more common than herbarium records suggest (Sundell 1986). Two recent collections confirm the presence of this species in southeast Kansas.

Voucher specimens: **KANSAS. Neosho Co.:** Chanute, S edge in Holiday Park, 29 Sep 1997, *Holland 9286*; St. Paul, near new Farmers National Bank, 2 Oct 1997, *Holland 9289*.

***Pyrus calleryana** Decne. (Rosaceae). A native of China, Bradford pear is widely cultivated as an ornamental tree in the U.S. Kartesz and Meacham (1999) mapped records from more than a dozen states in the central, southeast, and south-central U.S. Cultivated plants often persist after abandonment in the Great Plains, and field observations suggest that the species has escaped in Kansas more frequently than herbarium records indicate. A collection from the eastern part of the state comes from a tree that appears not to have been under prior cultivation.

Voucher specimen: **KANSAS. Douglas Co.:** Lawrence, SE edge. Baker Wetlands, just W pull-in on N side of site, T13S, R20E, sec 18, NE 1/4, NW 1/4, 38°55'40"N, 95°14'00"W, elev 250 m, weedy woodland along edge of wetland, 16 Nov 2000, *Morse 5289, Freeman & Loring*.

***Sagina apetala** Ard. (Caryophyllaceae). Crow (1978) mapped this diminutive, introduced annual from along the west coast of the U.S. and at several widely scattered sites in the southeast. Examination of KANU specimens recently revealed two overlooked specimens of hairy-leaf pearlwort from Kansas.

Voucher specimens: **KANSAS. Leavenworth Co.:** US 24 highway at Basehor, sandy, gravelly soil around roadside pull-off, exposed, 4 May 1983, *Brooks 16545*; US 24 at Basehor, roadside pull-off area, gravelly disturbed site, 8 Jun 1983, *Brooks 16638*.

***Sedum sarmentosum** Bunge (Crassulaceae). Stringy stonecrop is a succulent ornamental native to China (Gleason & Cronquist 1991). Escaped plants have been documented in most states east of the Great Plains (Kartesz & Meacham 1999). A small population recently discovered in eastern Kansas is the first record for the state.

Voucher specimen: **KANSAS. Miami Co.:** Beagle, 2.5 mi N, 2 mi E, T18, R22E, sec 25, S 1/2, NE 1/4, 38°27'22"N, 94°15'15"W, elev 275 m, grazed woodland along trail to S end of tallgrass prairie site, 28 May 2001, *Morse 5856 & Michener*.

Silphium radula Nutt. (Asteraceae). A member of the taxonomically difficult *Silphium integrifolium* Michx. complex, rough-stem rosinweed is reported from scattered populations throughout the southeastern U.S. (Kartesz & Meacham 1999). Previously reported in the Great Plains from Oklahoma and Texas (Great Plains Flora Association 1991), this species has been confirmed in southeast Kansas based on a single collection.

Voucher specimen: **KANSAS. Neosho Co.:** Erie, 0.25 mi S, 5 mi E, along old MKT RR right of way, 17 Jul 2000, *Holland 9959*.

***Trianthema portulacastrum** L. (Aizoaceae). Desert horse-purslane is an introduced species known from widely scattered collections in the southern Great Plains (Great Plains Flora Association 1977, 1991). Three collections were made in 2000 in Kiowa County, Colorado, representing the first records for that state.

Voucher specimens: **COLORADO. Kiowa Co.:** Eads, 8.5 mi S, 4 mi E, Neenoshe Reservoir, NW side, T20S, R47W, sec 6, NE 1/4, elev 3,930 ft, shortgrass prairie immediately W of the reservoir and open to wooded shoreline, 16 May 2000, *Freeman 14545*; Eads, 10 mi S, 4.5 mi E, Neenoshe Reservoir, S side, T20S, R47W, sec 9, SW 1/4, SW 1/4 & sec 16, N 1/2, elev 3,930 ft, open, sandy to muddy shoreline and adjacent, wooded perimeter of reservoir, 20 Aug 2000, *Freeman 15983 & Morse*; Eads, 8.5 mi S, 4 mi E, Neenoshe Reservoir, NW side, T20S, R47W, sec 6, NE 1/4, elev 3,930 ft, shortgrass prairie immediately W of the reservoir and open to wooded shoreline, 20 Aug 2000, *Freeman 16037 & Morse*.

Tridens flavus (L.) Hitchc. var. **chapmanii** (Small) Shinners. (Poaceae). *Tridens flavus* is broadly distributed throughout the eastern U.S., westward through Wisconsin and southward to New Mexico. Variety *flavus* occurs in the Great Plains from southeastern Nebraska, southward through eastern Kansas and into Oklahoma (Great Plains Flora Association 1977). Variety *chapmanii* has been reported from Oklahoma (Kartesz & Meachem 1999). Recent examination of specimens from southern Kansas revealed that this variety also occurs in the state.

Voucher specimens: **KANSAS. Chautauqua Co.:** Sedan, 1.5 mi NE, open blackjack oak woods, hillside, dry rocky sandstone soil, 18 Oct 1969, *Stephens 37321*; Chautauqua, 1 mi S, 1.5 mi E, low woods along small stream, soil sandy, moist, 14 Oct 1976, *Brooks 12832*. **Cowley Co.:** Winfield, 7 mi W, sandy prairie, 3 Sep 1966, *Koch 2100*.

***Veronica persica** Poir. (Scrophulariaceae). Though bird-eye speedwell was overlooked in the Flora of the Great Plains (Great Plains Flora Association 1991), Freeman et al. (1998) reported this introduced annual from Iowa, Kansas, Nebraska, South Dakota, and Wyoming in the Great Plains. According to Weber and Wittmann (1992), previous reports of *V. persica* in Colorado were based on misidentified specimens of *V. polita* Fr. However, a recent collection in eastern Colorado confirms the presence of this species in the state.

Voucher specimen: **COLORADO. Cheyenne Co.:** Cheyenne Wells, S side of town, T14S, R44W, sec 20, NW¼, SE¼, elev 4,260 ft, rest area along US 40 and adjacent Cheyenne County Fairgrounds, well-watered grass in outfield of ball diamond, 2 Oct 2000, *Freeman 16705*.

ACKNOWLEDGMENTS

We thank Carolyn Ferguson (KSC) for providing access to specimens at the Kansas State University Herbarium and Anton A. Reznicek (MICH) for confirming our determination of *Carex swanii*. David Sutherland and an anonymous reviewer provided valuable comments about the manuscript. Support for 2000 fieldwork in Colorado was provided by a grant from the Colorado Natural Areas Program. Other studies were funded in part by the Kansas Biological Survey and the University of Kansas Natural History Museum and Biodiversity Research Center.

Hydrology and the Management of Watersheds, Third Edition is basically a textbook on hydrology and watershed management for students of natural resources. A number of improvements to the third edition reflect the needs of students and instructors. The book is divided into six major sections: **1)** Hydrologic processes and land use; **2)** Erosion, sediment yield and channel processes; **3)** Water quality; **4)** Riparian and wetland management; **5)** Special topics including snow hydrology, watershed considerations for water resource development and engineering applications, hydrologic methods, and tools and technologies for watershed analysis and research; **6)** Socioeconomic considerations in watershed management.

THOMAS R. DEGREGORI. 2002. **The Environment, Our Natural Resources, and Modern Technology.** (ISBN 0-8138-0869-3, hbk.). Iowa State Press, 2121 State Avenue, Ames, IA 50014, U.S.A. (Orders: 1-800-862-6657, 1-515-292-3348 fax; www.iowastatepress.com). $79.99, 576 pp., b/w photos, graphs/figs., 6" × 9".

Contents: **1)** Green consumerism; **2)** Racism, elitism, and environmentalism; **3)** Life in the bush; **4)** Paradise in the Pacific?; **5)** The American Indian: The "original ecologist"?; **6)** Demystifying the environment; **7)** Technology and the "primitive"; **8)** The human endeavor as a creative force; **9)** Technology and the promise of modernity. ABSTRACT

Two species of *Corchorus* (Tiliaceae) are reported for Mexico: *Corchorus olitorius* L. of Asian origin and *C. trilocularis* L., native of the tropics of Africa and Asia. The first species was introduced into Brazil and the Antilles toward the end of the 19th century and is now recorded for Mexico from the state of Sinaloa. The second species is known from Veracruz and Chiapas, Mexico, and as well as Panama and Ecuador. The exchange and trade of seeds from other continents could be an important way for their introduction and that might explain the presence of these two species in Mexico. At present six species of *Corchorus* are known to occur in Mexico. A dichotomous key for the identification of the Mexican species of the genus is provided, as well as descriptions of the two species, a map of geographic distributions for these species in America, and their vernacular names.

KEY WORDS: *Corchorus olitorius, C. trilocularis*, aloctonous species, Tiliaceae, Mexico.

RESUMEN

Se dan a conocer dos nuevos registros de especies alóctonas del género *Corchorus* (Tiliaceae): *Corchorus olitorius* L. de origen asiático y *C. trilocularis* L., nativa de los trópicos de África y Asia. La primera especie fue introducido a Brasil y a las Antillas desde finales del siglo 19, en nuestro país se reporta por primera vez del estado de Sinaloa; la segunda especie se registra de Veracruz y Chiapas, México, ademas de Ecuador y Panamá, se desconoce la fecha exacta de su arribo al continente americano. Se propone que el intercambio y comercio de semillas provenientes de otros continentes, puede ser una vía importante para su introducción, lo que podría explicar su presencia en México. En la actualidad son seis las especies reconocidas de este género para México. Se proporciona una clave dicotómica para separar de el género *Corchorus* de México, así como la descripción de las dos especies, un mapa de distribución geográfica para estas especies en América y sus nombres comunes.

PALABRAS CLAVE: *Corchorus olitorius, C. trilocularis*, especies alóctonas, Tiliaceae, México.

INTRODUCTION

The genus *Corchorus* (Tiliaceae) was originally described by Linnaeus in 1753, who included four species in the genus: *Corchorus capsularis* L., *C. hirsutus* L., *C. olitorius* L., and *C. siliquosus* L. At the present time the genus is considered pantropical with approximately 40 species, with about 10 species in the New World (Howard 1989). *Corchorus olitorius* and *C. capsularis*, of Asian-African

[1]Fellowship COFFA, IPN

[2]Fellowship EDD, IPN

origin, have been cultivated since the XIX century in some tropical regions of America for their well known jute fiber.

In Mexico, Standley (1923) registers the presence of three species: *Corchorus hirtus* L., *C. orinocensis* Kunth, and *C. siliquosus* L.; later Standley and Steyermark (1949) recognize *Corchorus aestuans* L. for Mexico and South America; Fryxell (2001) recognize: *C. aestuans*, *C. siliquosos* and *C. hirtus* for the Flora Novo-Galiciana. In the present work *C. olitorius* and *C. trilocularis* L. are added to the previous list, resulting in six species presently reported for Mexico.

The genus *Corchorus* is characterized as follows: annual or perennial herbs, subshrubs, or shrubs, with simple, stellate, or stellate-dendritic hairs or glabrous; leaves alternate, simple, with stipules, persistent or deciduous; blades dentate, serrate or crenate, occasionally with two teeth prolonged into long setae at base; inflorescences lateral or leaf-opposed, bracteate, shortly pedunculate, 1-to several-flowered umbellate or racemose cymes; flowers hermaphroditic; calyx valvate, sepals 4–5, generally free, often apiculate or caudate at apex; petals 4–5, yellow, free, usually shortly unguiculate, with an inconspicuous glandular patch at the base of each petal; androgynophore usually present; stamens 4 to many, free, filaments free or connate; anthers with two theca, introrse, dorsifixed; ovary 2-to10-locular, ovules 2 to many per locule, placentation axile, parietal, or pendulous; style terete, papillate; capsules cylindrical to subglobose, muricate, glabrous, glabrescent, or pubescent, 2- to 10-valved, valves sometimes with transverse septae adaxially; seeds many and small.

METHODS

Specimens of *Corchorus* were studied in the herbaria CHAPA, ENCB, MEXU, UAS, and XAL. Specialized works on the genus were reviewed, with the morphological characteristics of stem, leaves and fruits being compared with the respective descriptions in the works of Martinez (1981), Edmons (1990), and Halford (1995). For the particular case of *C. trilocularis*, the pubescence of the fruit was observed in the compound microscope. The specimens were also compared with the phototypes of the herbarium S-LINN, deposited in the ENCB herbarium. Synonymies and vernacular names were taken from literature sources.

RESULTS

Two species of *Corchorus* are added to the family Tiliaceae in Mexico, *C. olitorius* and *C. trilocularis*. The first one is native of the region of India and Malaysia and is widely cultivated for its fiber, well known as jute. *Corchorus trilocularis* is native to the region of Africa and Asia and is less important from a economic point of view, not being a commercial crop. A dichotomous key for the identification of all Mexican species of *Corchorus* is included below, followed by morphological descriptions, uses, and specimens examined for each of the two newly reported species, as well as a distribution map (Fig. 1).

KEY TO THE SPECIES OF *CORCHORUS* IN MÉXICO

1. Subligneous more than 1 m tall; ovary with 5–6 celled; capsules with 5–6 _____ **Corchorus olitorius**

1. Herbs smaller than 1 m tall; ovary with 2–4 celled; capsules with 2–4 valves.
   2. Capsules 2 valved; ovary 2 celled.
      3. Shrubs; branchlets subglabrous; leaves glabrous below; ovary puberulent; capsules aplanate with the apex obtuse and with 1–4 minute apical beaks ____ **Corchorus siliquosus**
      3. Herbs; branchlets densely tomentose and hirsute; leaves hirsute or pilose below, ovary densely sericeous; capsules teretes without apical beaks.
         4. Capsules hirsute with trichomes conspicuous ca. 1.5 mm long, lightly curved; stipules and leaves hirsute; calyx hirsute; stamen 40; ovary hispid _____ **Corchorus hirtus**
         4. Capsules glabrous or with trichomes inconspicuous ca. 1 mm de largo, right; stipules and leaves essentially glabrous; calyx glabrous; stamens 20–30; ovary appressed pubescent _____ **Corchorus orinocensis**
   2. Capsules 3–4 valved; ovary 3–4 celled.
      5. Leaves mostly ovate, slightly cordate, base rounded and sometimes with a pair of teeth prolonged; stamens 9–14, capsule oblongoid with 6–8 winged and 3 or 4 apical bifid beak divergent and recurved _____ **Corchorus aestuans**
      5. Leaves narrowly ovate or linear, base obtuse or broadly cuneate never with a pair of teeth prolonged, stamens 20–30, capsule torulose without winged and only one apex straight _____ **Corchorus trilocularis**

Corchorus olitorius L. Sp. Pl. 529. 1753. (**Figs 1, 2**). TYPE: cultivated specimen *Herb. Clifford 209, Corchortus no. 1*, (LECTOTYPE: BM). Lectotype designated by Wild, Fl. Zambes. 2:84. 1963.

Corchorus olitorius var. *australiensis* Domin, Biblio. Bot. 89:380. 1927

Vernacular names in other countries, taken from the literature.—bunani waweza, eteke nyamusiri, niimbaswa-lusali, otigu-kal, pombo mgunda (Africa); yute (Argentina); gramigrain (Bahamas); yute, gringuele (Cuba); bogi, koshta, jute, chehuncho, changhas, rajaan, tossa jutee (India); feuilles lalo, lalo, petit lalo, tila-lo (Dominican Republic-Haiti).

Subligneous herb to (1–)2–4 m tall; branchlets glabrous, somewhat angular or sulcate when young, stipules 5–16 mm long, glabrous; leaves with petioles terete, thin, (1–)3–4(–60) mm long, glabrous except for simple hairs on a margin; stipules linear, (7–)10(–12) mm long, pilose or glabrous; blades narrowly ovate to ovate, ovate-lanceolate, (1.5–)10(–12) cm long and (1–)2–5 cm wide, upper and lower surfaces usually glabrous, veins sometimes pilose, base rounded and with two basal setaceous teeth to 10(–15) mm long, margin serrate to crenate-serrate, apex acute to acuminate; inflorescences leaf-opposed, solitary

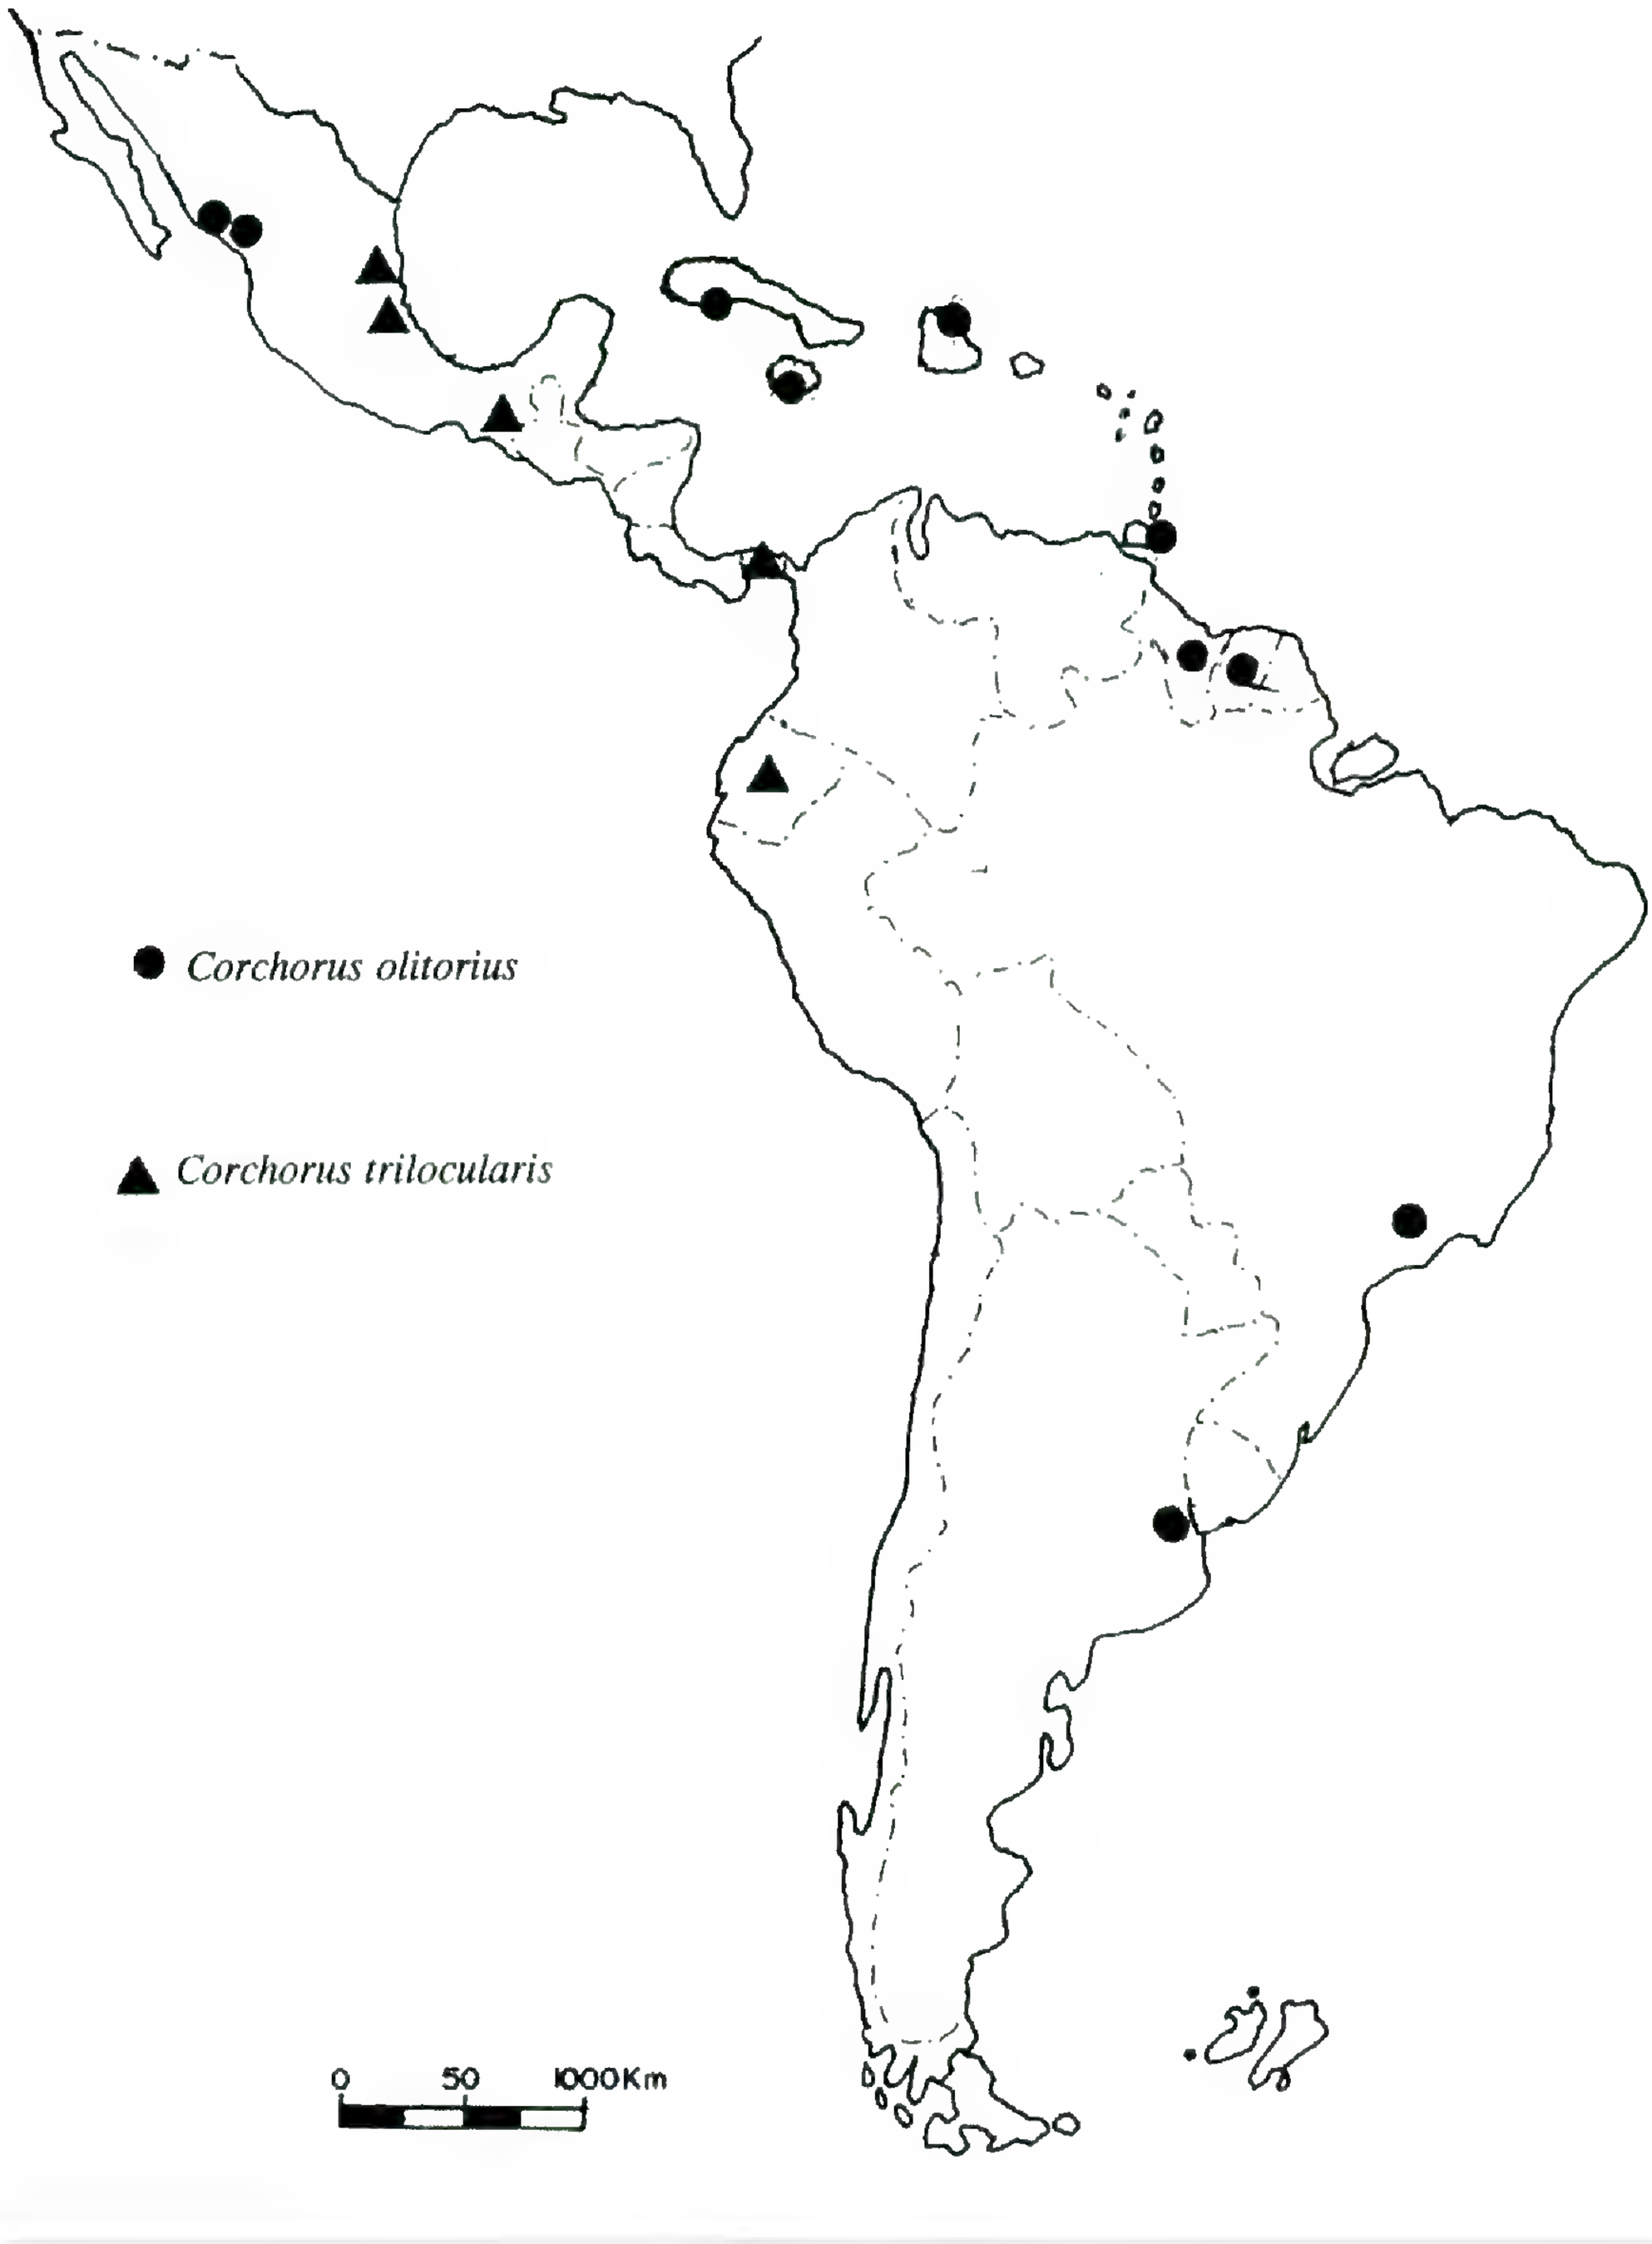

FIG. 1. Geographical distribution in America of *Corchorus olitorius* and *C. trilocularis*

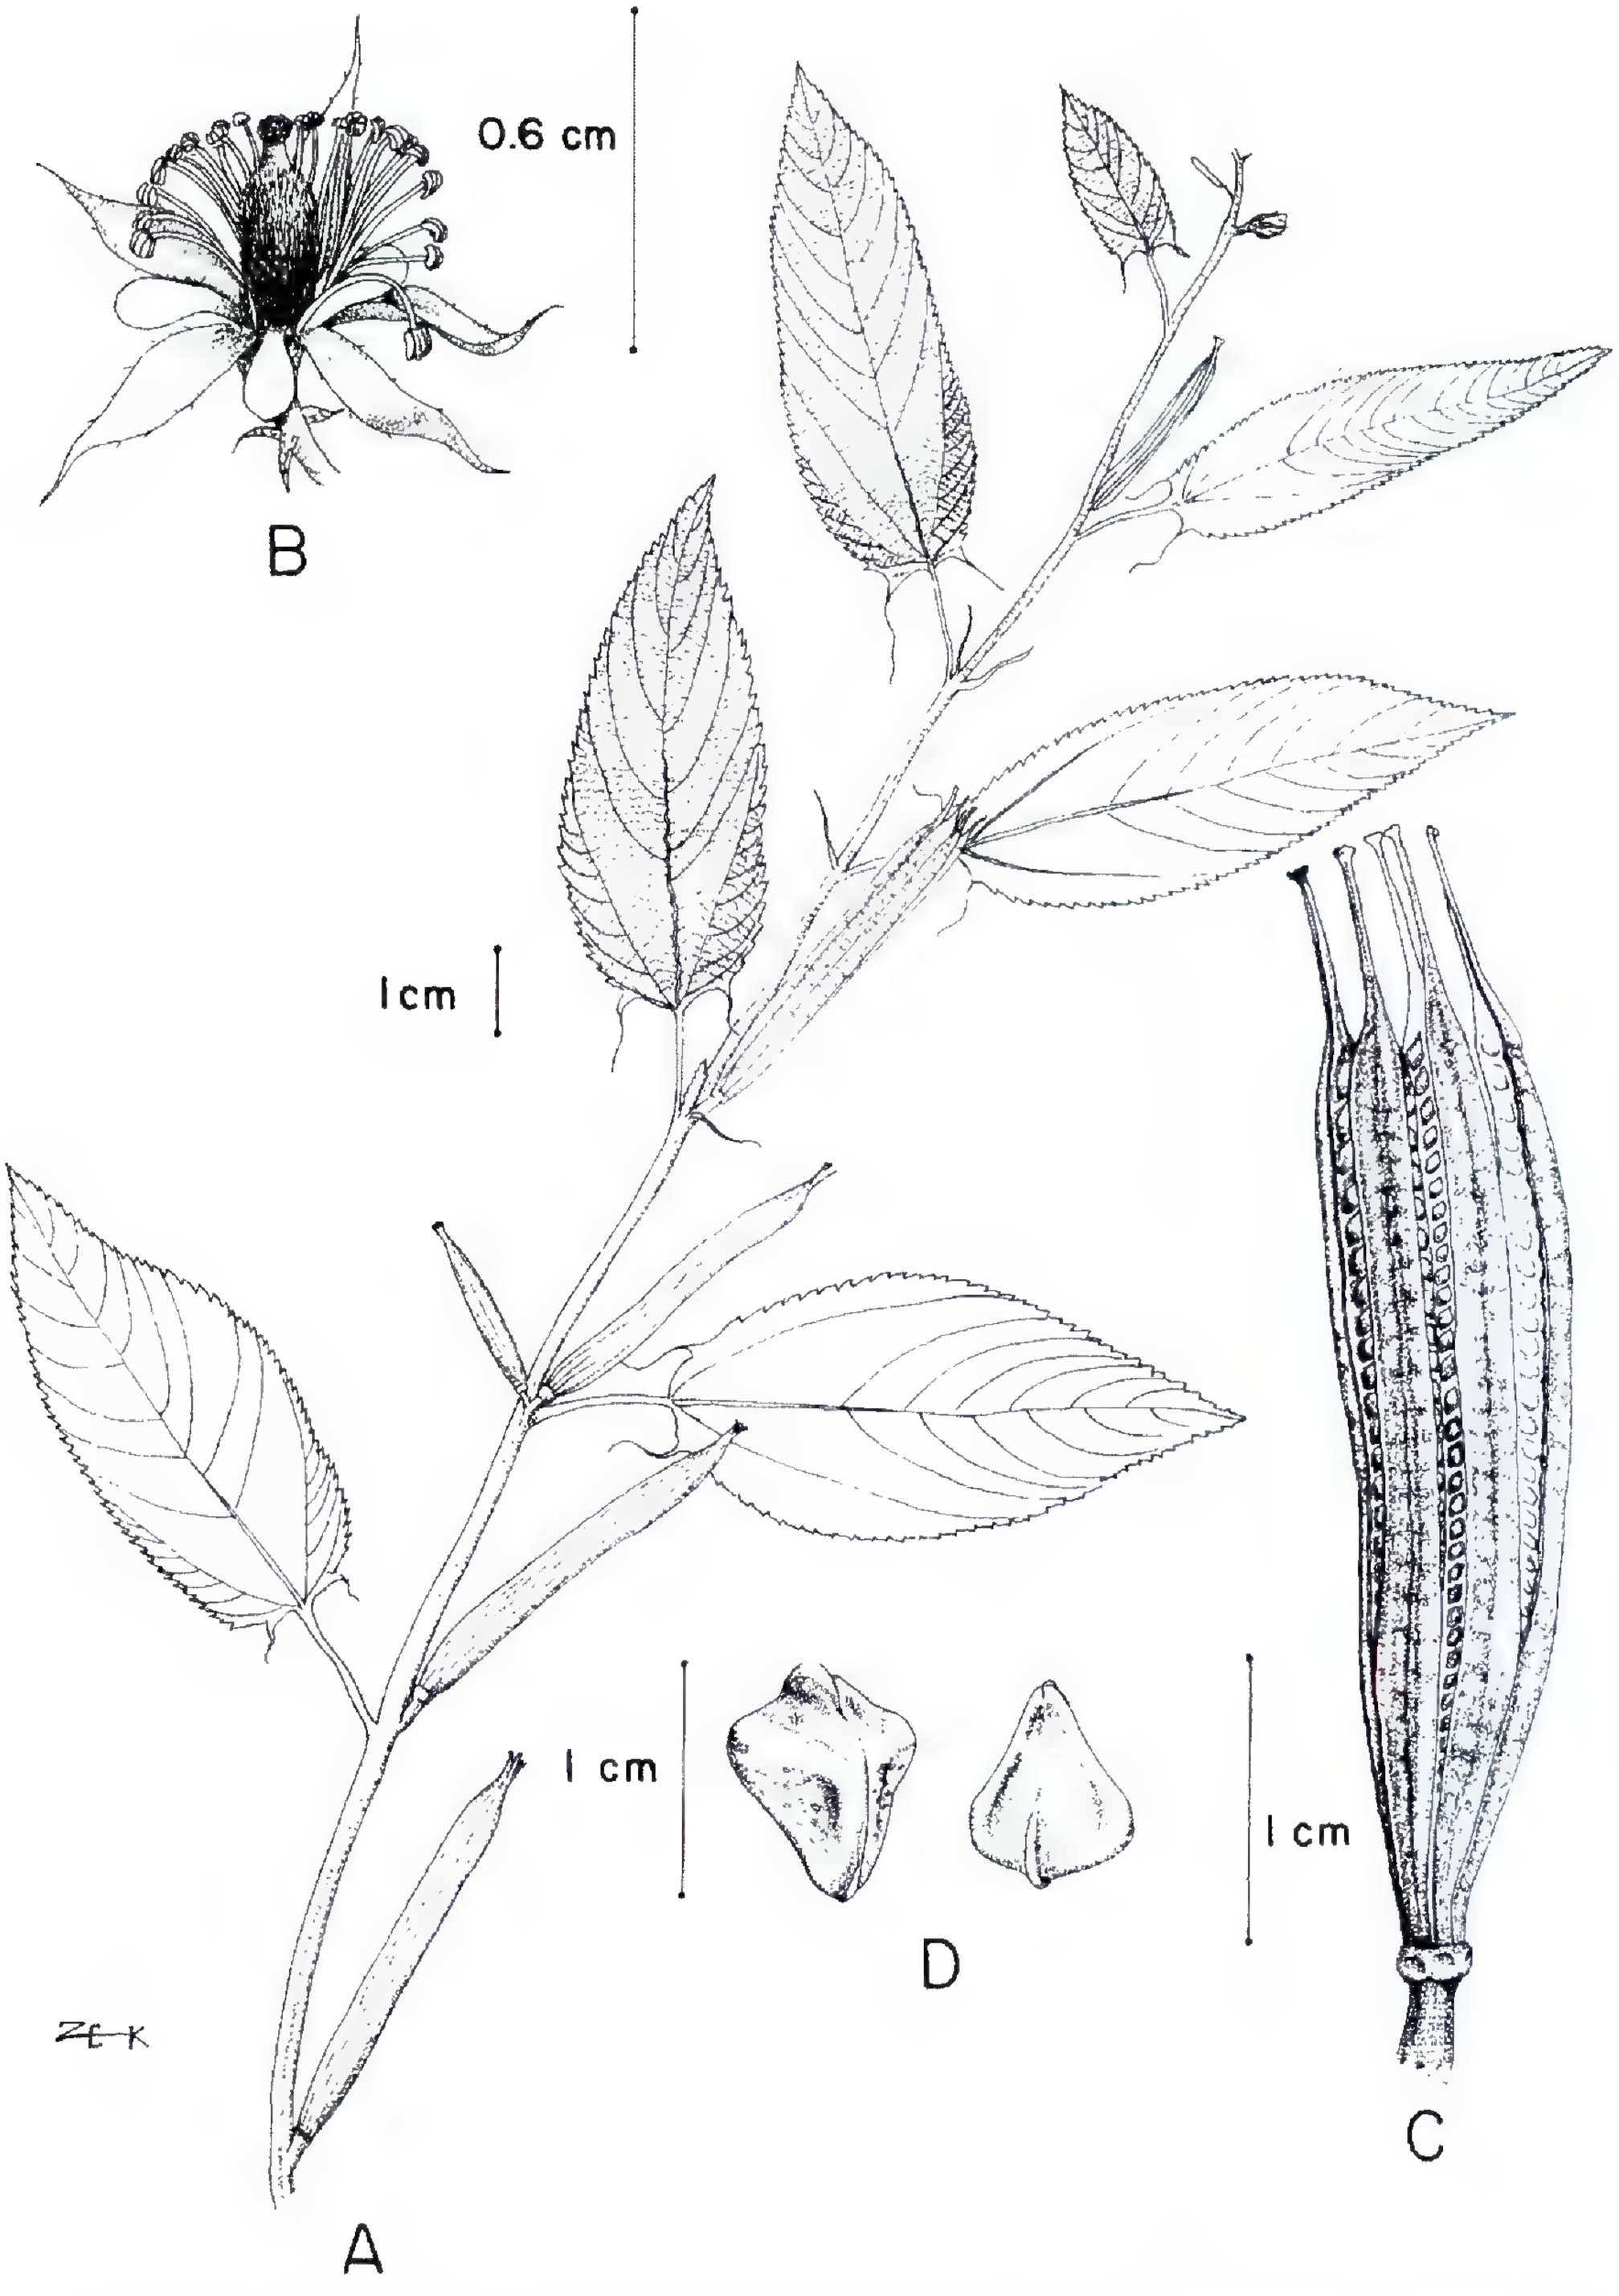

FIG. 2. *Corchorus olitorius* L. **A.** Branch with leaves, buds and fruits; **B.** Immature flower, seen laterally; **C.** Lateral view of the fruit; **D.** Seeds (based on *D. Bates, O. Blanchard and P. Fryxell 1543*).

at the nodes, geminate or ternate, pedicels very short, 1–2 mm long, glabrous, bracts (1–)3–5 mm long, pilose o glabrous; sepals valvate, 7 mm long, linear-lanceolate, concave and glabrous; petals obovate, imbricate, yellow, same length as sepals, 1 mm long and 2–3 mm wide, glabrous but minutely ciliate on margin; androgynophore 2–5 mm long; annulus 5-lobed; stamens 30–50, borne inside of annulus; filaments filiform, 3–4 mm long; anthers dorsifixed, oblong; ovary cylindrical, 5–6 celled, 10-sulcate, minutely setose and glandular, with 36–42 axial ovules per cell; style stout, glabrous, 1–2 mm long, stigma lobed, fimbriate; capsule cylindrical, (3–)4–6(–8) cm long and (3–)4–5(–6) mm wide, appressed to stem, sometimes torulose, dehiscent, 5–6 valvate, transversely septate, apex 3 to 4(–10) mm long; seeds more or less rhomboid, many, black, 1–3 mm (Fig. 2).

Specimens examined: **MÉXICO. Sinaloa:** a 2 Km del ejido La Campana, km 25 carr. Culiacán Guamuchil, municipio de Culiacán, *Leobardo Chávez Montes* y *Fco. Javier Niebla Armenta 124* (UAS); carr. Culiacán-Los Mochis, Km 19, al NE hacia el Cerro La Chiva, *J. A. Prado V.* y *V. Llamas A. 201* (UAS); pie del Cerro El Tule, lado W, orilla de la brecha a la torre de microondas, ca. 5 km de Culiacán, municipio de Culiacán, *Rito Vega. 7295, Hipólito Aguiar H., Cenón Aguirre C.* y *Ricardo Cebreros B.* (UAS); carretera internacional a Costa Rica Km 5, municipio de Culiacán, *Salomé Ochoa Avalos* y *Germán A. Bojórquez B. 162* (MEXU); El Camichin, a 3 km al poniente de Guadalupe de los Reyes, municipio de Cosalá, *Rito Vega 3487, Germán Bojórquez* y *Alejandro Hernández* (CHAPA, UAS); 5 mi S of Mazatlan, *D. Bates, O. Blanchard* y *P. Fryxell 1543* (ENCB).

This species is originally from India and Malaysia, with pantropical distribution where it is appreciated for its fiber (jute).

Corchorus olitorius can be distinguished from the rest of the species in Mexico by being a semishrub 1–2 m, with the stem and leaves glabrous and the inferior border of the leaves with two very long appendices, as well as by the linear capsule, which is thick and glabrous with five valves. It is known from the Pacific Coastal Plain, in the state of Sinaloa, where it grows on the edges of cultivated fields, the banks of roads, in tropical deciduous forest and in thorn forest, on alluvial soils and thin and stony soils, at altitudes that vary between (30–)50 and 700 m. Its presence in America has been reported since the latter part of the XIX century in most of the region of the Caribbean and Brazil (Ricardo et al. 1995; Schumann 1886).

From very early times *Corchorus olitorius* was cultivated as edible in Africa and the Middle East, while as a textile plant it was broadly domesticated in India (Simmonds 1979). Well known as jute, it is presently cultivated in the west of Bengal, Bangladesh, Burma, Nepal, China, Malaysia, and Sri Lanka (Maiti 1995). With the same objective it was introduced into Brazil and Cuba at the end of the 19th century, and in the latter country it has become naturalized in the western part (Schumann 1886; Ricardo et al. 1995; Rodríguez 2000). In Argentina its presence may be more recent (Dimitri & Rial 1952).

This species occurs in Africa in grassland and savannas, and diverse uses are attributed to it there, such as paper production and the extraction of indus-

trial alcohol (Irvine 1961; Edmons 1990). In India, the seeds are used as a purgative and an infusion of the leaves is used as a tonic (Bhandari 1978).

Corchorus trilocularis L. Syst. Nat. ed. 12, 2:369.1767. (**Figs. 1, 3**). TYPE: protologue ARABIA: *Forsskål s.n.* (LINN 691.2) type info. fide Flora of Tropical East Africa (2001).

Vernacular names in other countries, taken from the literature.—apoik, lumere, teke (Africa); hardikaket, kagle-ki-tambaku, karak (India).

Herbs, procumbent to ascending, up 50 cm tall; branchlets moderately covered with pilose pubescence; leaves simple, petioles 3–20 mm long with simple hairs, stipules 2–3(–7) mm long; blades narrowly ovate or linear, (2.5–)4–9(–13) cm long and 0.6–3.0 cm wide, base obtuse or broadly cuneate never with a pair of teeth prolonged, margin dentate or crenate, sometimes with a pair of basal teeth upwardly prolonged 5(–10) mm, apex obtuse or acute, upper surface with scattered simple hairs, lower surface with simple hairs frequently on midvein and secondary veins; inflorescence leaf-opposed, solitary at nodes, geminate or ternate, peduncles and pedicels 1–2(–4) mm long, bracts up 33 mm long, ciliate; sepals 5, linear, (4–)5.5–(–6.3) mm long and 10 mm wide, pilose outside, constricted toward base; petals 5, obovate, (4–)5–(6–)7 mm long and 20–25 mm wide, minutely ciliate on margin; stamens 20–30; ovary cylindrical, 3-locular, 3 mm long, shortly pubescent, stigma fimbriate; capsule torulose without winged and only one apex straight, (2.5–)3.0–5.5(–7) cm long and (1–)2.5–3 mm wide, 3-valvate, pubescence of short simple and fasciculate or palmate hairs, the latter not perceptible without magnification, at maturity more or less glabrous, apex straight, acuminate, valves partially transversely septate adaxially; seeds more or less rhomboid, dark brown to black, 0.8–1 mm diameter.

Specimens examined: **MÉXICO. Chiapas:** Mirador for Chicoasen Dam along road to Tuxtla Gutierrez to the Chicoasen, Municipio San Fernando, *Breedlove 41494* (MEXU). **Veracruz:** Barranca de Pachuquilla, a 2 km al SO de dicha población, municipio de Puente Nacional, *M. E. Medina A.* y *M. Ortiz D. 702* (XAL); Paso de la Milpa, municipio de Actopan, *F. Ventura A. 18001* (ENCB, XAL); Cerro del Brujo, 3 km al N de Jacomulco, municipio de Jalcomulco, *G. Castillo Campos* y *P. Zamora C. 8757* (XAL); Al NW de Jalcomulco, entre Tuzamapan y Jalcomulco, municipio de Jalcomulco, *G. Castillo-Campos, et al. 8347* (XAL); El Hatito, carretera de terracería El Hatito-Caño Prieto, municipio de Paso de Ovejas, *J. E. González H. 184* (XAL); Mata de Caña, municipio de Puente Nacional, *F. Ventura A. 10706* (ENCB). **PANAMÁ. Provincia Los Santos:** Las Trancas-Guararé, *Alcibiades Velázques 24* (MEXU).

Corchorus trilocularis resembles *C. orinocensis* in its herbaceous habit and the size of the leaves. However, *C. trilocularis* is distinguished by the presence of small sepals and petals and the fimbriate stigma; by the ovate-lanceolate leaf

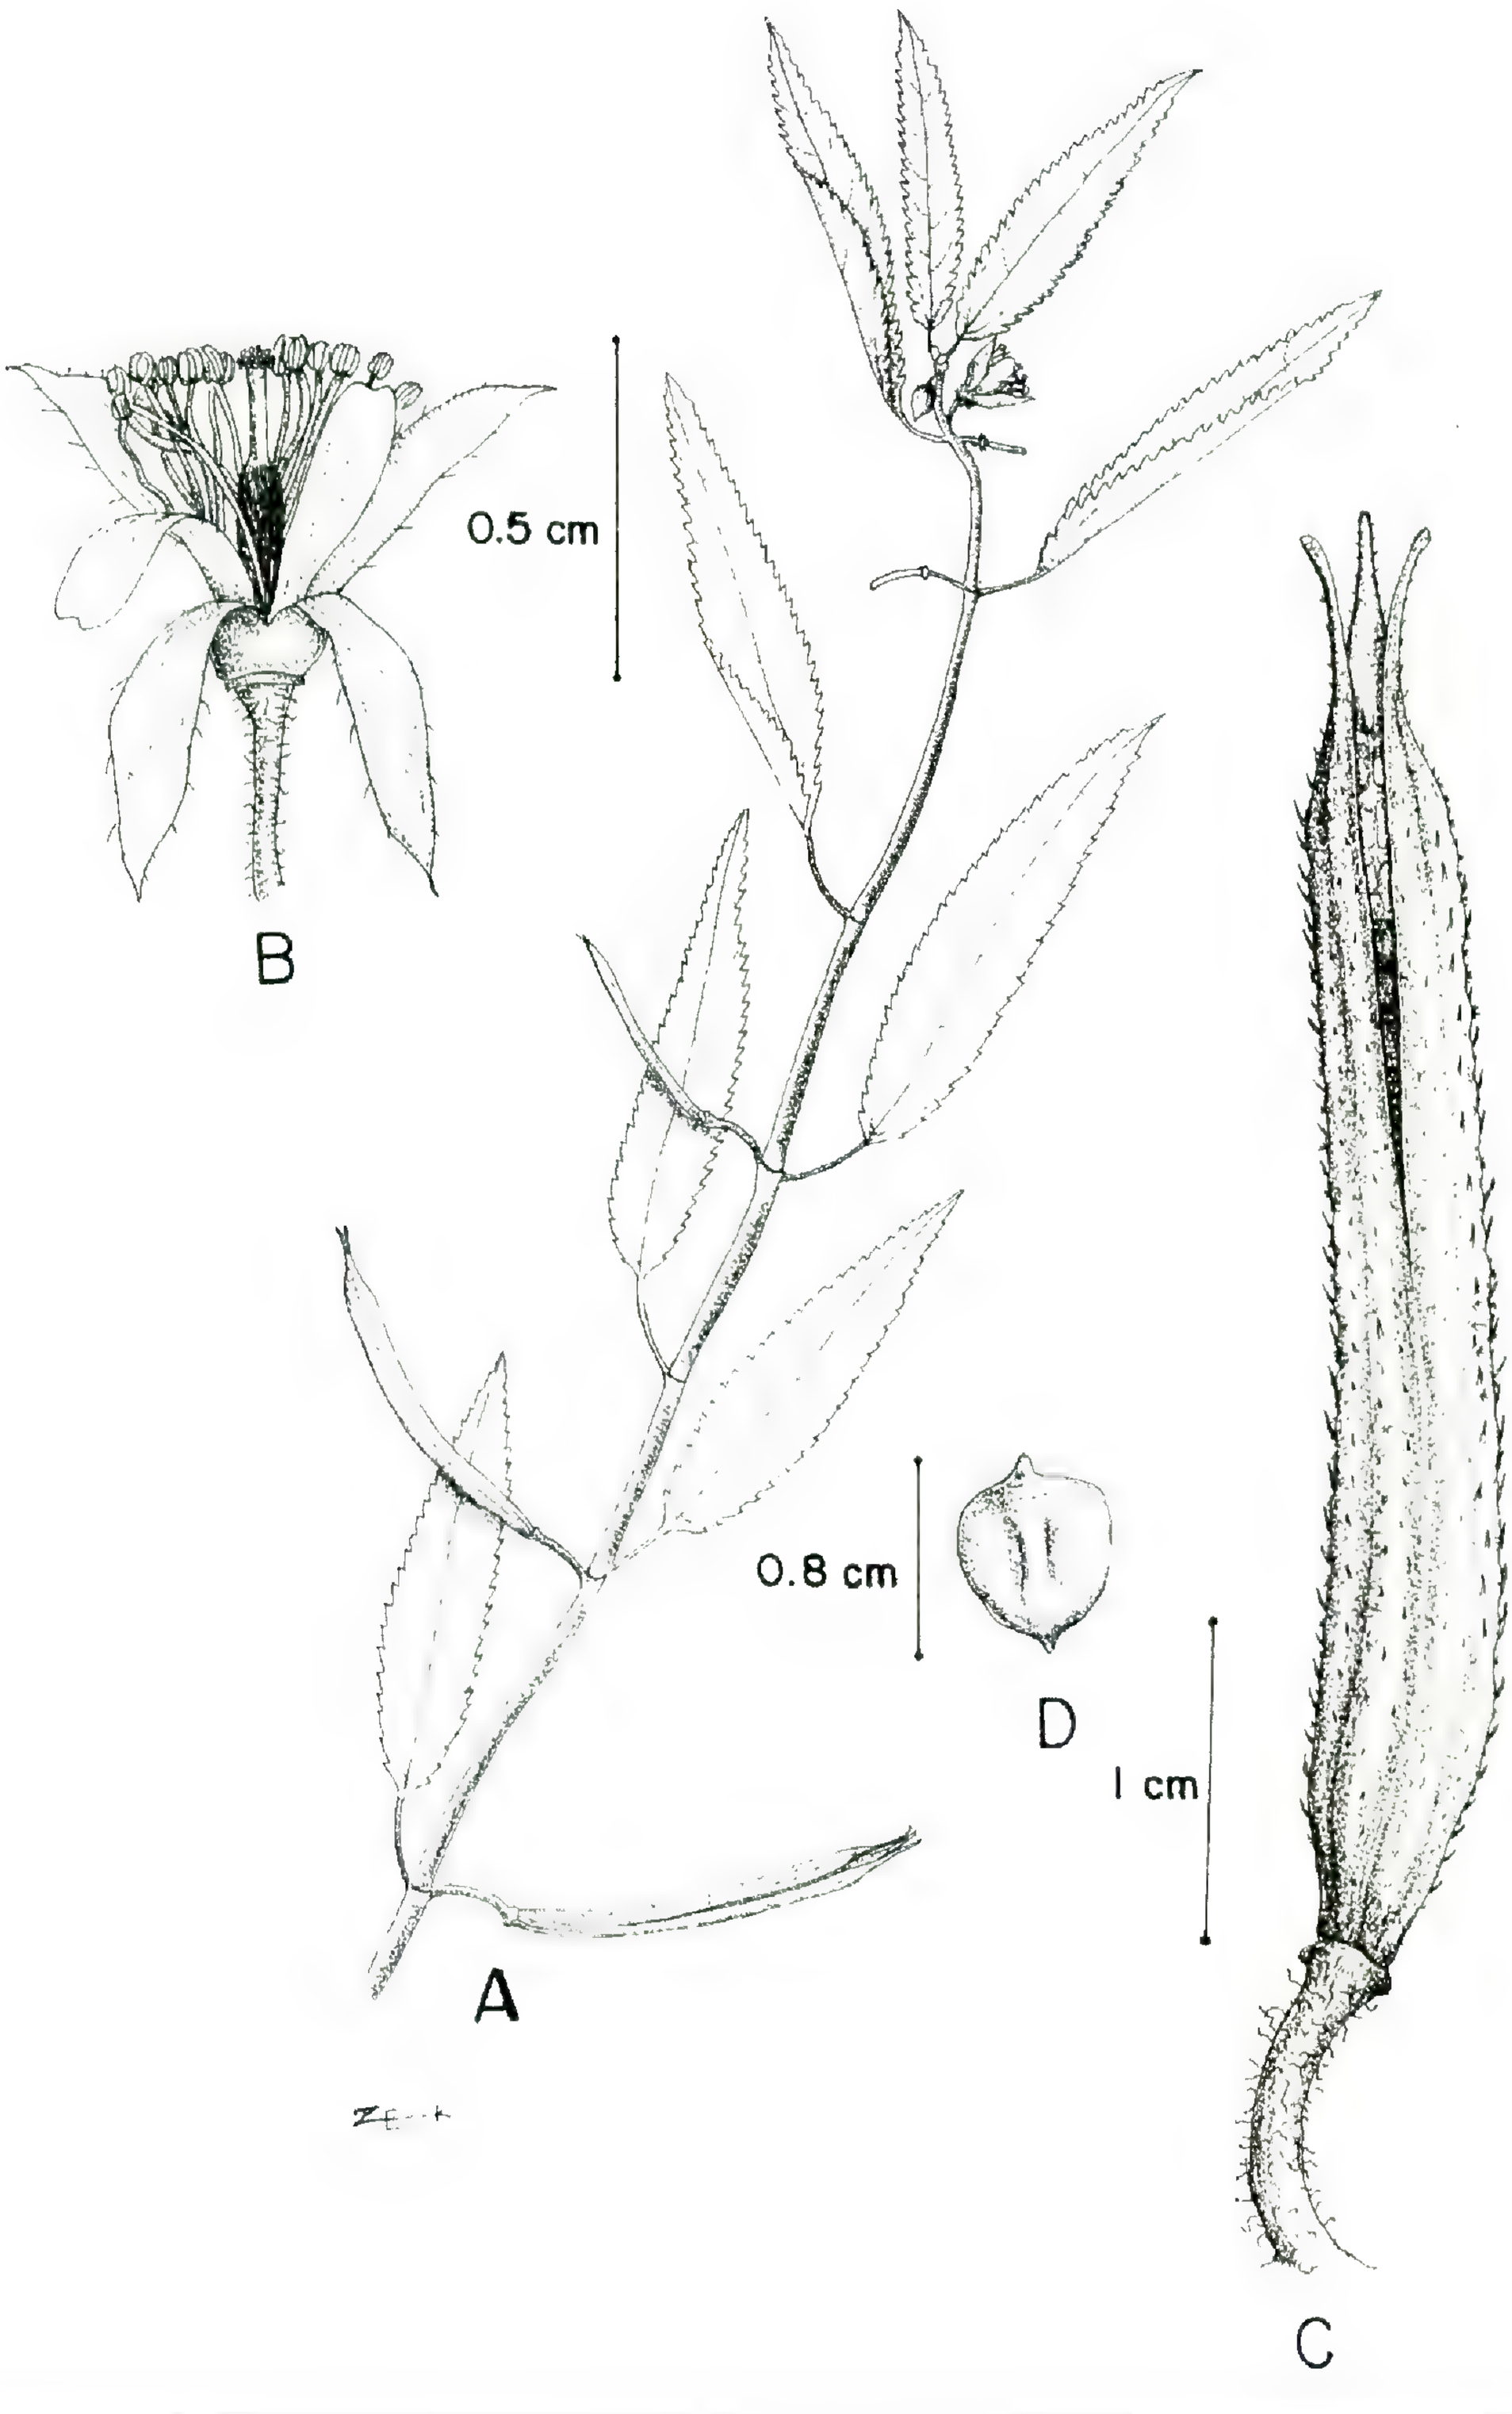

FIG. 3. *Corchorus trilocularis* L. **A.** Branch with leaves, buds and fruits; **B.** Mature flower, seen laterally; **C.** Lateral view of the fruit; **D.** Seeds. (based on *A. Velázquez 24*)

blade (linear-lanceolate in *C. orinocensis*); and, most remarkably, by its three-valved fruits with pubescence of simple and fasciculate or palmate hairs, the latter extremely small and imperceptible at first look (Fig. 3), as opposed to the two-valved fruits with only simple hairs found in *C. orinocensis*.

The presence of *Corchorus trilocularis* in America has not been established previously with certainty, because specimens with two or three-valved fruits have been identified as *Corchorus orinocensis*. In the earlier works of Macbride (1956) for Peru and Robyns (1964) for Panama, the descriptions of *Corchorus orinocensis* correspond to three-valved material.

In the revision of the Neotropical species of the genus *Corchorus*, Tiliaceae, Martínez (1981) assigned Ecuadorian specimens to *Corchorus trilocularis*.

In the revision of the family Tiliacae for the Flora of the Guyanas, Jansen and Meijer (1995) have concluded that only the two-valved specimens should be assigned to *C. orinocensis* based on Kunth's 1823 description.

Corchorus trilocularis is widely distributed in Africa, Asia, and Australia, including in the xerophytic regions of Arabia and India (Bhandari 1978; Edmons 1990). At present there is no clear indication of the date of arrival in the Americas. In Mexico it has been collected in the states of Chiapas and Veracruz, in disturbed areas of deciduous and semi-deciduous tropical forest and in Panama in tropical rain forest.

Although *Corchorus trilocularis* is of little economic importance, it is used at the domestic level; for example, in Africa, the leaves are used in traditional medicine to reduce swellings; an infusion of leaves and branchs is used to produce an alcoholic drink; the seeds are used for certain stomach disorders and to induce vomiting; and it is used as an ornamental plant and as food for livestock (Edmons 1990).

CONCLUSIONS

With these two new reports of *Corchorus*, the number of species known for Mexico rises to six. *Corchorus olitorius* is presently known only from Sinaloa, although its presence in the region of the Caribbean and South America as a useful plant has long been known. Its origin in the Indo-Malay region and its discovery in the Pacific coastal plain in Mexico leads to the supposition that trade of agricultural products, mainly seeds with Oriental countries, has been the route of introduction of the species into Mexico.

In Mexico *Corchorus trilocularis* behaves as weed adapted to the disturbed conditions in southern Mexico, in dry and sub-humid warm vegetation types and in cloud mountain forest. In the Old World it is a characteristic species of the arid zones of Africa, Arabia, and India, in areas of cultivations, grasslands, savannas, and xerophyllous shrubs, while it is also present in the warm-humid zones of India and Australia. Its presence in the Ecuador and part of Central America leaves unanswered questions about this apparently disjunct distribution.

In the specimens of *C. trilocularis* collected in Mexico and Central America, we observe that the pubescence of the mature capsule is of simple and fasciculate trichomes similar to specimens collected in Australia (Halford 1995). Specimens collected in Africa present mature capsules with simple and palmate trichomes (Edmons 1990).

It seems likely that more intensive collection in Mexico, Mesoamerica, and South America will lead to a more definite hypothesis as to the manner and route of introduction of the species into the New World, including whether the introduction is recent or ancient.

ACKNOWLEDGMENTS

The authors thank Pedro Leyva for the specimen drawing, and curators of the herbaria cited here for access to their valuable collections. The first author thanks COTEPABE, IPN (Project CGPI S99001) for financial support to visit the Missouri Botanical Garden herbarium in August 2000.

ABSTRACT

Thelypteris rhachiflexuosa Riba, described from Veracruz is recorded from Chiapas, where it was found in Northern Highlands. Additional data about distribution, habitat, and morphology are discussed.

RESUMEN

Thelypteris rhachiflexuosa Riba, descrito de Veracruz, es registrado para las Montañas del Norte de Chiapas. Se discute información sobre su distribución, hábitat y morfología.

INTRODUCTION

The genus *Thelypteris* comprises about 900 species—distributed around the world—with high diversity in the tropical and subtropical regions. One hundred thirty three (133) species have been recorded for Mesoamerica and about 50% of these are found in Chiapas (Smith 1995).

The Northern Highlands of Chiapas is one of the less well known areas from a botanical viewpoint (Breedlove 1981). Nevertheless, a few studies have been carried out in this area (Pérez & Sarukhán 1970; López-Mendoza 1980), and it has been considered one of the most important regions for endemic taxa (Schutzman et al. 1988; Went 1989, 1998). Unfortunately it is also one of the most altered places, due mainly to anthropogenic activities (cattle raising and sun coffee plantation). This has resulted in loss of both primary vegetation and floristic diversity.

During a floristic exploration of the tropical forests in the Northern Highlands in 1999, we collected several samples of ferns, among them a *Thelypteris* with a flexuose rachis and 2–4 pairs of alternate, undulate pinnae.

This specimen proved to be *Thelypteris rhachiflexuosa* Riba, previously known only from the region of Los Tuxtlas, Veracruz. This species was collected and described by Riba (1989) and recorded as endemic to Veracruz (Ibarra-Manríquez et al. 1997; Riba & Pérez-García 1997; Riba 1998).

Voucher specimen: **MEXICO. Chiapas:** Mpio. Amatán, Mt. Palmar, 10 km E of Amatán, Northern Highlands, 23 May 1999, 800 m, *Pérez-Farrera 1967*; (Herbarium of Escuela de Biologia, UNICACH; CHIP) (Fig. 1). *Thelypteris rhachiflexuosa* is being grown in the Botanical Garden "Faustino Miranda" in the Instituto de Historia Natural under accession number 085.

In Chiapas this species occurs in "bosque tropical perennifolio" (tropical rain forest) according to Rzedowski (1978), or "selva alta perennifolia" (Miranda & Hernández-X. 1963). This vegetation is comprised of three strata. The first stratum is dominated by *Brosimum alicastrum* Sw., *Dialium guianense* (Aubl.) Sandw., *Manilkara zapota* (L.) Royen, *Guatteria anomala* R.E. Fries, *Calophyllum brasiliense* Camb., *Pouteria sapota* (Jacq.) H.E. Moore & Stearn, and *Pterocarpus hayensii* Hemsl. In the middle stratum are usually *Bursera simaruba* (L.) Sarg., *Pimenta dioica* (L.) Merrill, *Miconia trinervia* (Sw.) D. Don. ex Loud., *Oreopanax xalapensis* (Kunth) Decné & Pl., *Trophis racemosa* (L.) Urban, *Saurauia belizensis* Lundell, and *Dendropanax arboreus* (L.) Planch. & Decne. The third stratum or understory typically consists of *Astrocaryum mexicanum* Liebm., *Chamaedorea concolor* Martius, *Chamaedorea elegans* Martius, *Chamaedorea tepejilote* Liebm., *Chamaedorea arenbergiana* Wendl. *Desmoncus chinantlensis* Liebm. *Begonia nelumbiifolia* Cham. & Schlecht., *Anthurium pedatoradiatum* Schott, *A. schlechtendalii* Kunth. In addition, some epiyphytes and hemiepiyphytes are found in these habitats, e.g., *Monstera deliciosa* Liebm., *Anthurium pentaphyllum* (Aublet) G. Don. var. *bombacifolium* (Schott) Madison, and *Polypodium* sp. *Thelypteris rhachiflexuosa* is sometimes found in secondary vegetation or coffee plantations.

The soils in this area are red clay derived from lutitas (López-Mendoza 1980). The topography is abrupt, with steep slopes (70%). The landscape is karstic and the bedrock consists of a complex of Eocene and Oligocene marine limestone (López-Hernández 1994; Pérez & Sarukhán 1970). This species occurs at elevations from 600–800 m (Fig. 2).

DISCUSSION

Thelypteris rhachiflexuosa is in the subgenus *Goniopteris*. In Mesoamerica about 41 species are known in this subgenus, with about 34 species in Mexico (Yatskievych, pers. comm.), and approximately 17 in Chiapas (Smith 1995). There are still taxonomic problems at the species level.

This record for Chiapas extends the distribution of this species into Mesoamérica. This taxon has a distribution pattern similar to that of other woody species restricted to the Caribbean slope, an area including Los Tuxtlas, Veracruz and northern mountains of Chiapas (Wendt 1998). We expect that *T. rhachiflexuosa* will also be found in the State of Tabasco.

Thelypteris rhachiflexuosa is similar to *T. oroniensis* L.D. Gómez, endemic to Costa Rica, in its zig-zag rachis, but differs from that species in its meniscioid secondary veins. The specimen of *T. rhachiflexuosa* collected in Chiapas dif-

FIG. 1. Herbarium voucher *Thelypteris rhachiflexuosa* from Chiapas.

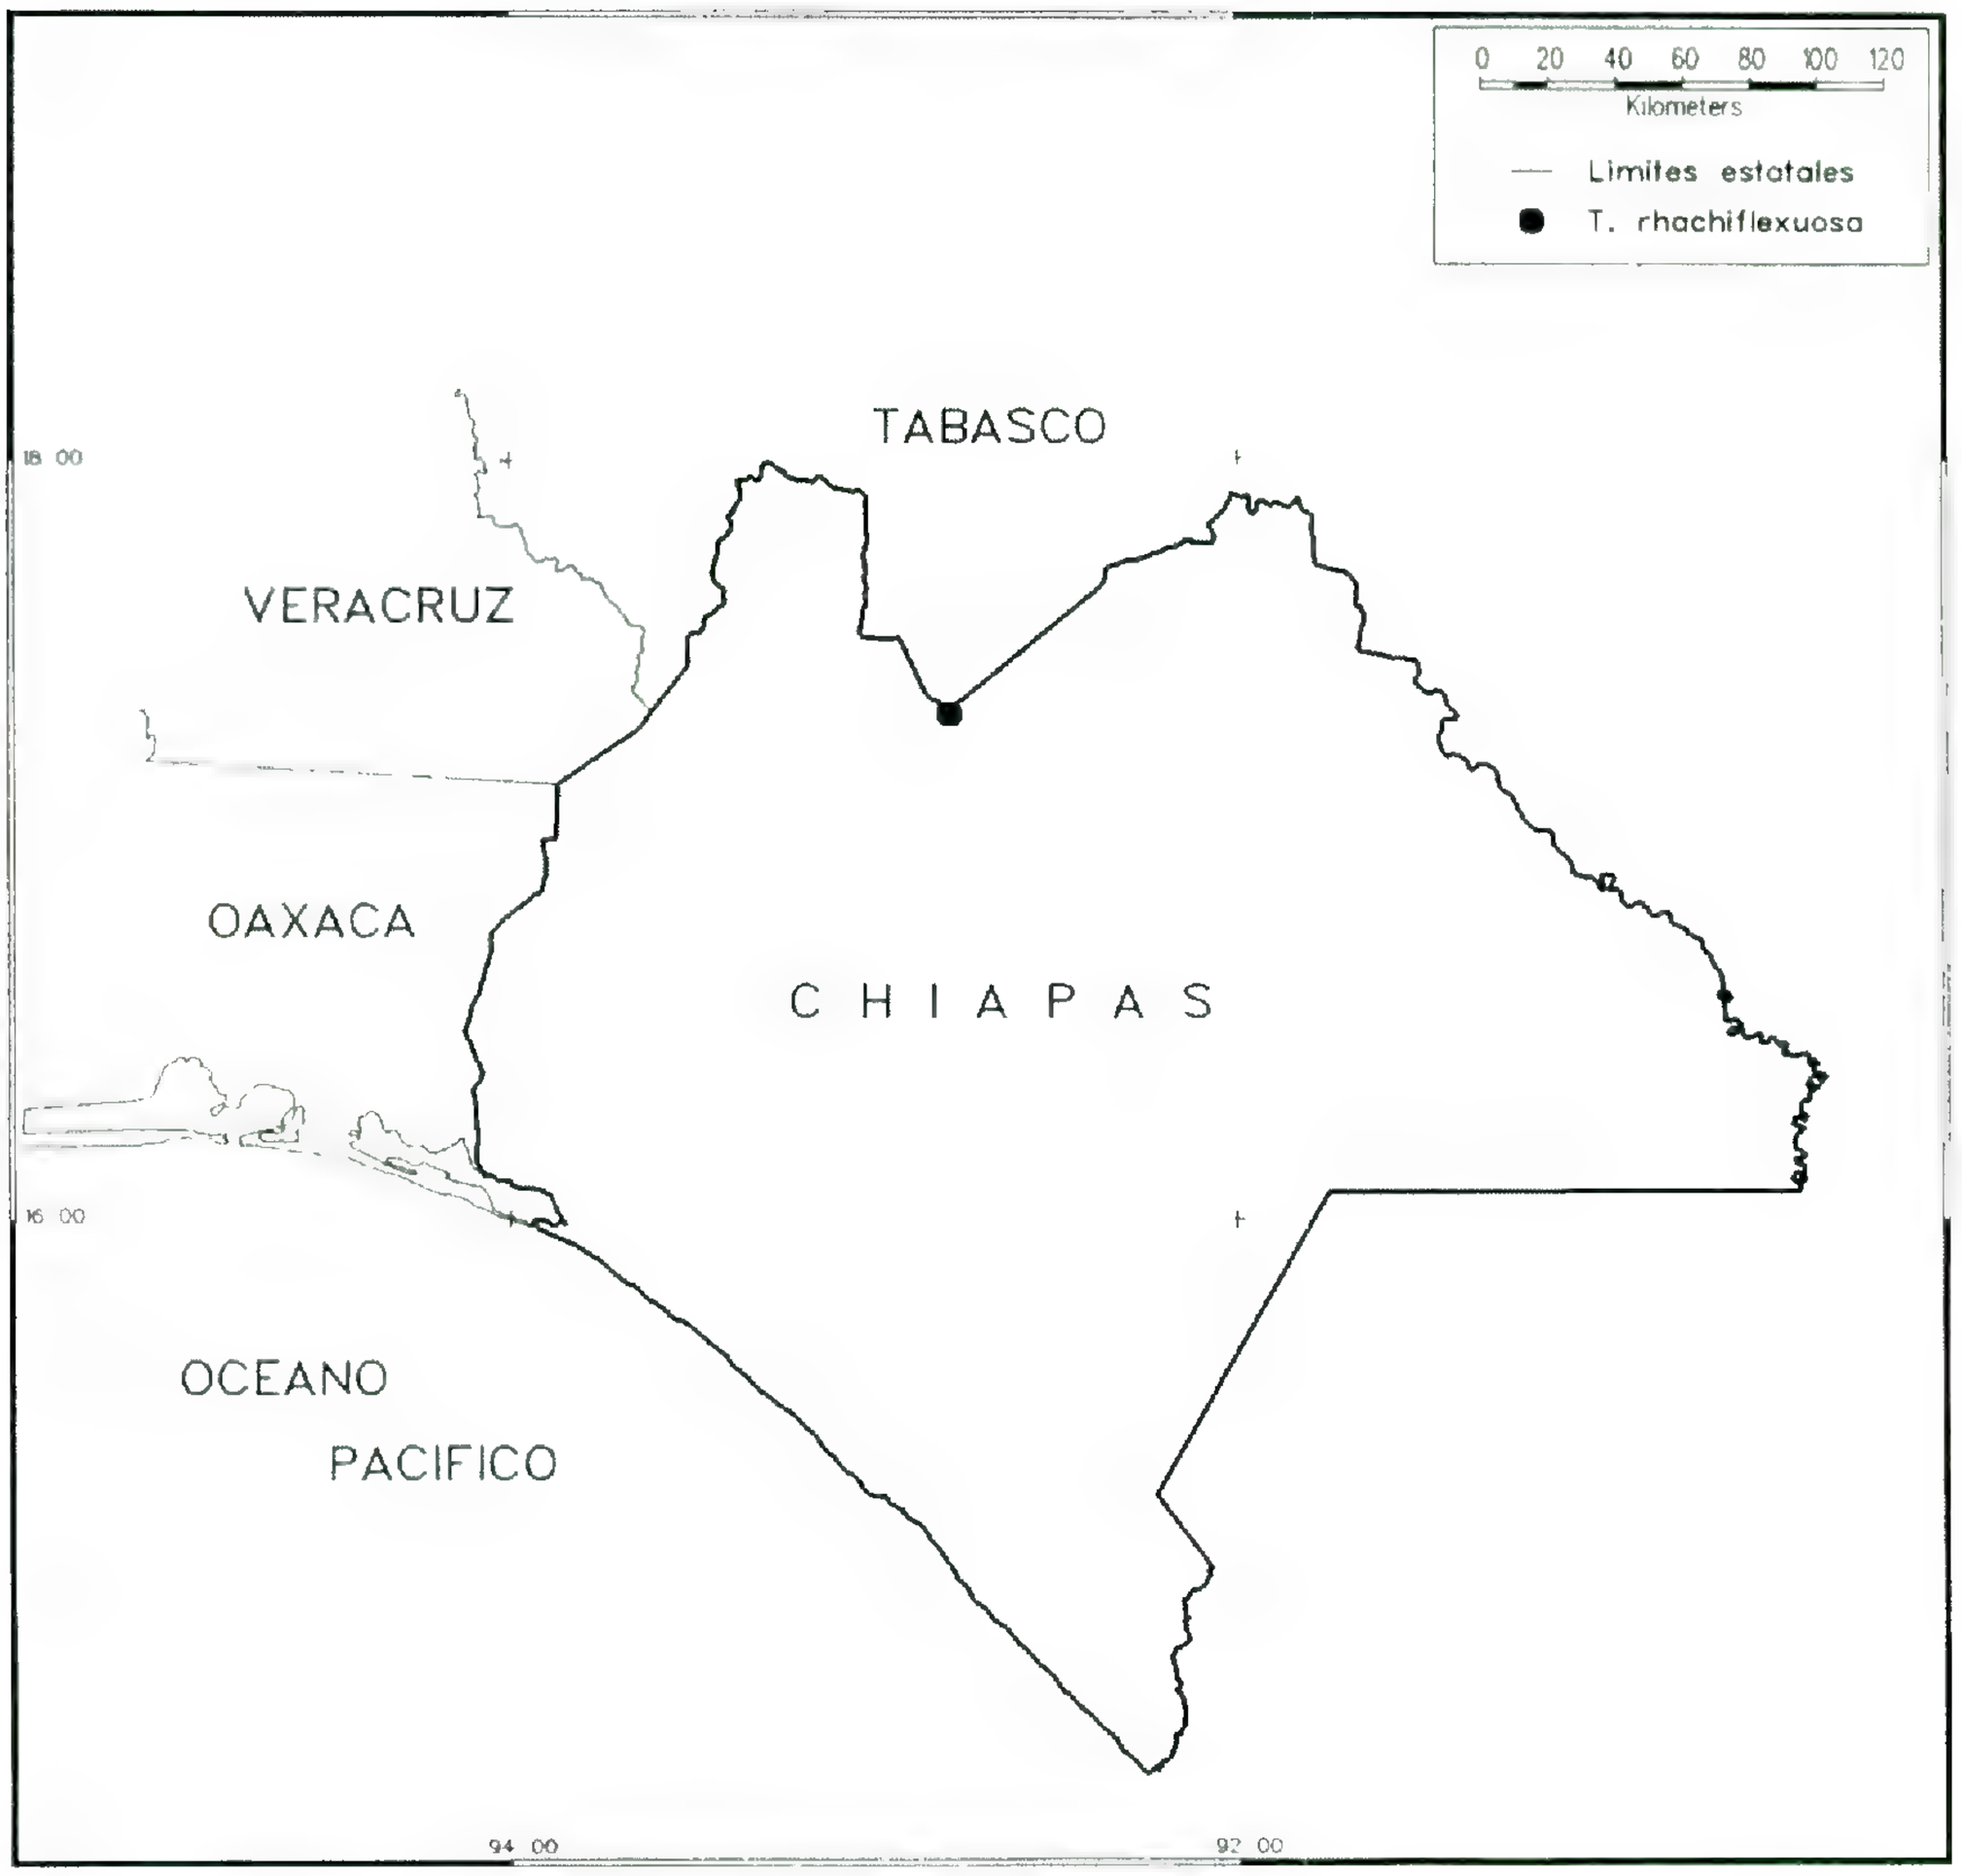

Fig. 2. Distribution of *Thelypteris rhachiflexuosa* in Chiapas.

fers slightly from the voucher collected in Veracruz in having more setulose sori. *Thelypteris rhachiflexuosa* sometimes grows with *Thelypterisghiesbreghtii* (Hook.) C.V. Morton and differs from this species with regard to straight rachis, costae, veins and leaf tissue moderately to densely hairs below.

ACKNOWLEDGMENTS

The authors thank Jesús de la Cruz Rodríguez, Emerit Meléndez López, Tomas Acero Acero, Oscar Farrera Sarmiento, and Francisco Hernández Najarro for their help in the field work and processing of plants. Special thanks to Blanca Pérez García and M. en C. Eleazar Carranza for their comments in the manuscript, Alan Smith and George Yatskievch for helpful comments, and Biól. Laura Noble Camargo for help with the map. The first author thanks the Escuela de Biología de la Universidad de Ciencias and Artes de Chiapas for financial support to explore the northern zone of Chiapas.

Note.—The first and third authors would like dedicate this manuscript to the memory of Dra. Ramón Riba y Nava Esparza, who passed away three hours after checking the identity of this species.

coste_amihai@hotmail.com

François J. Tardif

Department of Plant Agriculture
University of Guelph
Guelph, Ontario, N1G 2W1, CANADA
ftardif@uoguelph.ca

Polygonum douglasii E.L. Greene subsp. *johnstonii* (Munz) Hickman is native to western North America. Its presence in southwestern Canada was to be expected since it has been recorded from several adjacent American states—Washington, Idaho, Montana and North Dakota (Kartesz 1999)—that share common habitats with the southern parts of the western Canadian Provinces. It has not been recorded from Saskatchewan until now (Vernon Harms, pers. com.). Subspecies *johnstonii* grows on sandy soils, open rocky places in dry grass communities and Ponderosa forests. It flowers from June to August. Four point collections in the grasslands from southern Saskatchewan are indicated on the map that accompanies the herbarium label of the specimen cited. Since its occurrence is also probable in Alberta and British Columbia, further research is necessary to determine its exact distribution in Canada. The closest related taxon is *Polygonum douglasii* subsp. *douglasii* (Hickman 1984). *Polygonum douglasii* subsp. *johnstonii* differs from subsp. *douglasii* mainly through the erect, almost sessile or short-pedicellate achenes. Subspecies *douglasii* has spreading or reflexed, long-pedicellate achenes). Other distinguishing characters, an identification key and line drawings of the two taxa can be found in Hickman (1993).

Voucher specimen: **CANADA. Saskatchewan:** Grasslands Park, 9 mi SE of Val Marie, 17 Jul 1989, *E.R. Hooper 11110* (USAS).

ACKNOWLEDGMENTS

We thank Vernon Harms for confirming the novelty of the taxon in Saskatchewan; George Ledingham for the additional information about the collection from USAS; and Luc Brouillet for reviewing the manuscript.

KOENIGIA ISLANDICA (POLYGONACEAE) NEW FOR UTAH

Mihai Costea[1]

Department of Plant Agriculture
University of Guelph
Guelph, Ontario, N1G 2W1, CANADA
coste_amihai@hotmail.com

François J. Tardif

Department of Plant Agriculture
University of Guelph
Guelph, Ontario, N1G 2W1, CANADA
ftardif@uoguelph.ca

Koenigia islandica L. is a circumpolar species that extends south in North and South America, in scattered alpine summits of the Rocky Mountains and the Andes (Löve & Sarkar 1957; Freeman, unpublished). It occurs in alpine communities growing in permanently moist gravel or moss, especially around persistent nival basins near small streams, ponds, and lakes at elevation up to 3800 m (Freeman, unpublished). Sub-national conservation status has been assessed to S1 (critically imperiled) in Montana, Wyoming (U.S.A.), Alberta and Manitoba (Canada), S2 (imperiled) in Colorado (U.S.A.) and S2S3 in British Columbia, Labrador and Newfoundland (Canada). The species is possibly extirpated (SH) from Ontario, Canada (NatureServe Explorer 2002).

Voucher specimen: **U.S.A. UTAH. Duchesne Co.:** Ashley Forest, Uinta Mountains, Uinta drainage, Gilbert Bench E of Gilbert Peak, T5NR4W S24 N1/2 USM, elevation ca. 3600 m, alpine community, growing in a seep, apparently rooted in moss, 9 Aug 2000, *S. Goodrich, A. Huber, F. Bartlett and J. Frandsen 26308 (5)* (BRY, NY).

Koenigia islandica can be mistaken with seedlings of *Epilobium* spp. or with dwarf plants of *Polygonum minimum* Small. In the latter case, it can be easily distinguished by its opposite or whorled leaves and the flowers with 3 tepals and 3 stamens (*P. minimum* has alternate leaves and flowers with 5 tepals and 8 stamens).

ACKNOWLEDGMENTS

We warmly thank Stanley Welsh for confirming our finding and Craig Freeman for sharing with us his unpublished treatment of *Koenigia* for FNA.

Hobe Sound, FL 33455, U.S.A.

ABSTRACT

New distribution records of *Agalinis* species are reported including *Agalinis harperi* Pennell new to Texas.

RESUMEN

Se citan nuevas localidades de especies de *Agalinis* incluyendo *Agalinis harperi* Pennell nueva para Texas.

Agalinis harperi Pennell grows in the southeastern United States from South Carolina westward to Louisiana (Godfrey & Wooten 1981; Vincent 1982). It is on the Louisiana Natural Heritage Program's watch list for rare species (Louisiana Natural Heritage Program 1999). Hays (1998) recently clarified the nomenclature for this species, previously named *A. pinetorum*.

A population of approximately 500 plants was discovered in northern Newton County growing in an open rocky barren on Scrappin Valley, a hunting preserve and Habitat Management Area (HMA) for the Red-cockaded woodpecker owned by Temple-Inland Forest Products Corp. The species has not been reported for Texas (Hatch et. al. 1990; Jones et. al. 1997), but it has been collected in four Louisiana parishes bordering Texas (MacRoberts 1989; Thomas & Allen 1998; Vincent 1982). *Agalinis harperi* is similar to *A. purpurea* (L.) Pennell but can be distinguished by the more narrowly-linear, usually ascending leaves (0.5–1 mm) and by the longer distance between nodes, and thus by a more sparse vegetative appearance.

Voucher specimen: **TEXAS. Newton Co.:** Scrappin' Valley, open, rocky Catahoula barren in RCW cluster 2368E, 31.144499° N and 93.798482° W, 15 Oct 1999, *Keith* s.n. (BRIT.)

Agalinis filicaulis (Benth.) Pennell is also found in the coastal plain from Georgia westward to southwestern Louisiana (Godfrey & Wooten 1981; Vincent 1982). It is listed as an S1 species by the Louisiana Natural Heritage Program (Louisiana Natural Heritage Program 1999). Until recently, only one record of this species was known west of the Mississippi River in Allen parish (Vincent 1982; Thomas & Allen 1998; Louisiana Natural Heritage Program 1999). One

SIDA 20(3): 1321–1322. 2003

new record in Beauregard Parish and a collection from Vernon Parish previously reported in Thomas and Allen (1998) extend the range of this species. The Vernon Parish specimen was found on the edge of a nearly level pitcher plant bog, while the Beauregard Parish specimen was found in a wet open pine savannah. Both of these areas are burned frequently and have a predominately herbaceous understory. This species should be looked for in similar habitats in eastern Texas.

Voucher specimens: **LOUISIANA. Beauregard Parish:** in a wet pine savannah in RCW cluster 6230A approximately 4 mi E of Singer, 30.637805° N and 93.342741° W, 30 Oct 2001, *Keith 26* (BRIT). **Vernon Parish:** edge of pitcher plant bog, 2.5 mi ESE of Fort Polk in Fort Polk Intensive Use Area, 18 Sep 1997, *Keith s.n.* (NLU).

ACKNOWLEDGMENTS

Many thanks to the employees of Temple-Inland Forest Products Corp. including Don Dietz, Stan Cook, Bill Goodrum, Robert Wilson, and Jason Sebesta who have always been helpful and accommodating. Michael MacRoberts of Bog Research and an anonymous reviewer provided many helpful suggestions.

Rodgers (1950), Watson (1982), Johnston (1990), Texas Natural Heritage Program (1995), Jones et al. (1997), and Kartesz and Meacham (1999) include *Oxypolis ternata* (Nutt.) A. Heller in the Texas flora, apparently on the basis of a 1947 Lincoln Constance annotation of a 1945 V.L. Cory specimen (*Cory 49902* [GH]) from Hardin County that was identified initially as *Cynosciadium digitatum* DC. The Constance annotation reads: "?*Oxypolis ternata*." This apparently led Rodgers (1950) to include *O. ternata* in the Texas flora (Rodgers did not annotate *Cory 49902*) and Watson later (see Johnston 1990:57) to include it in her Big Thicket National Preserve plant list from which it has subsequently been copied by others. A search of Watson's vouchers revealed no *Oxypolis ternata* (Brown n.d.).

We examined *Cory 49902* and a duplicate at BRIT and found them to be narrow leaved *O. rigidior* (L.) Raf., which is a common morphological variant of that species over much of its range. Both specimens have paired leaflets and reticulate veins, characters of *O. rigidior* but not of *O. ternata*. Another troublesome Texas specimen has been *Correll 34924* [TEX] collected in Angelina Co. in 1967 and annotated to *O. ternata* by A.O. Tucker in 1980. It was annotated to *O. rigidior* by B.L. Turner in 2000 and reconfirmed to be *O. rigidior* by Tom Wendt (pers. comm.) in 2003. We also examined the Mathias and Constance (1961) treatment of Texas Apiaceae and found that they listed *Cory 49902* as an example of *O. rigidior* but did not mention *O. ternata* as occurring in Texas. A search of ASTC, BRIT, DUKE, F, FLAS, FSU, NCU, SBSC, SHST, TAMU (on line), TEX, and VDB revealed no Texas specimens of *O. ternata*. We have collected specimens of *O. rigidior* from Tyler County, adjacent to Hardin County, that are almost identical in appearance to *Cory 49902*. These have been deposited at TEX.

As far as we can discern, *O. ternata* occurs no closer to Texas than the cen-

tral Florida panhandle (Wunderlin 1998; Florida Atlas of Vascular Plants [www.plantatlas.usf.edu]).

Within volume twenty, number two, of this journal, Griffith and Bartel (2002) answered our request (Karges & Zech 2001) for further study and documentation of *Cupressus arizonica* within the Davis Mountains of Jeff Davis County, Texas. While the effort has been made, we found several problems with the attempt, including the main points of concern that follow. Of the three additional specimens sampled from Jeff Davis County there is no indication that any were collected from the Davis Mountains, let alone the Davis Mountains Preserve (DMP). We're puzzled as to why fresh material of the Jeff Davis County *C. arizonica* or *Juniperus deppeana* from the DMP were not included for chloroplast DNA analysis. Both would have been made available upon request. Griffith and Bartel (2002) cite two specimens of the Jeff Davis County *C. arizonica*. *Karges and Hedges 2480* is the only existing specimen, a second specimen, *Karges s.n.*, was never collected. Griffith and Bartel's (2002) reference to, and discussion of, a mixed specimen is most puzzling, since neither Hedges (pers. comm.) nor Karges collected reproductive material.

Perhaps the chloroplast DNA data does suggest that the Jeff Davis County Arizona Cypress is Alligator Juniper. However, this study's discrepancies, along with the admittedly low 63% bootstrap, leave us unconvinced. We still recognize the tree in question as *C. arizonica*, and most importantly, continue to encourage additional, careful, study of this unique tree.

ABSTRACT

A rockhouse microhabitat located in the xeric savannah/woodland community of the West Cross Timbers of North Central Texas is discussed and an associated disjunct population of *Arisaema triphyllum* is reported.

RESUMEN

Se discute un microhábitat rocoso en la comunidad sabana/arbolado de West Cross Timbers en el centro-norte de Texas y se cita una población disyunta asociada de *Arisaema triphyllum*.

"Rockhouses" or rockhouse cliff formations are deep recesses in bedrock cliffs that can maintain microhabitats that are highly buffered from the extremes in temperature and moisture typical of the surrounding macroenvironment (Farrar 1998). As discussed by Walck et al. (1996), in comparison with the outside macroenvironment, rockhouse habitats tend to be more shaded, have higher temperatures during the winter, lower temperatures during the summer, and have lower rates of evaporation and higher relative humidities. Not only is there less evaporation, but water often enters via groundwater seepage, in some cases providing a relatively stable supply of moisture. In addition, condensation on the rock walls further increases humidity locally. The result is a rockhouse can provide microclimatic conditions very different (more moderated) from those typically found in a given geographic area.

There are numerous such rockhouse habitats in various areas of the eastern United States, particularly in sandstone strata. Several recent papers (Walck et al. 1996; Farrar 1998) have discussed these rockhouses and the interesting plant taxa now known to occur in them. According to Walck et al. (1996), 11 plant taxa are endemic or nearly endemic to sandstone rockhouses in the eastern U.S. Particularly interesting is the occurrence in rockhouses of a number of bryophytes and ferns with tropical affinities (Farrar 1998).

While relatively common in the eastern U.S., such rockhouse environments seem unlikely in the West Cross Timbers of North Central Texas—particularly

since hard surface rocks are unusual in most of the region. Such rocks, however, can be found in the area known as the Palo Pinto Country in the northwestern portion of the West Cross Timbers. This rather rugged region is underlain by the oldest rocks exposed in North Central Texas, deposited during the Pennsylvanian Period. These rocks vary, but are "largely made up of soft, impure shales alternating with harder, coarse, brown sandstone and conglomerates" (Hill 1901). In one area of western Parker County, where Pennsylvanian sandstones/conglomerates are exposed, deep recesses have formed that are worthy of the term rockhouse. Striking rock walls approximately 40 feet (12 meters) tall form narrow passageways and recesses. It has been known for a number of years that one unusual plant distributional record is associated with this environment. *Carya ovata* (Mill.) K. Koch, shag-bark hickory (Juglandaceae), is disjunct to this area by about 100 miles (275 kilometers) from its main region of occurrence in East Texas (e.g., *Lipscomb 2321*, 1977—BRIT). The site is also the westernmost locality in Texas for *Asplenium platyneuron* (L.) Britton, Sterns, & Poggenb., ebony spleenwort (Aspleniaceae) (Turner et al. 2003).

The moderated microclimate of this sheltered rockhouse microhabitat stands in rather sharp contrast to the macroclimate of the exposed upland West Cross Timbers macrohabitat/community. While yearly average precipitation in the area is approximately 29 inches (74 cm) (Griffiths & Orton 1968; Hatch et al. 1990), rainfall is unevenly distributed with summers typically being extremely hot and dry. As a result, the upland vegetation has a distinctly dry area aspect—a savannah/woodland with stunted *Quercus stellata* (post oak) and *Quercus marilandica* (blackjack oak), an understory of grasses (Diggs et al. 1999), and even such xerophytic, mainly western species as *Berberis trifoliolata* Moric. (agarito), *Echinocereus reichenbachii* (Terscheck ex Walp.) F. Haage (lace cactus), *Juniperus ashei* J. Buchholz (mountain-cedar), *Mimosa borealis* A. Gray (catclaw), *Opuntia leptocaulis* DC. (pencil cholla), *Zanthoxylum hirsutum* Buckley (prickly-ash), and *Ziziphus obtusifolia* (Hook. ex. Torr. & A. Gray.) A. Gray (lotebush).

Several years ago, another disjunction was discovered by one of us (O'Kennon). A large population of *Arisaema triphyllum* (L.) Schott, jack-in-the-pulpit (Araceae), was found in the mesic microhabitat between rock walls (Figs. 1 and 2) in the same extensive rockhouse as *Carya ovata* (voucher: *O'Kennon 16024*—BRIT). Interestingly, even though we estimate the population at approximately 2,000 above ground stems (the number of genetically distinct individuals is unknown), it had not been reported previously in the literature, possibly due to confusion with the related widespread species, *Arisaema dracontium* (L.) Schott, (green-dragon). The locality information was provided to Turner et al. (2003) for inclusion in the *Atlas of the Vascular Plants of Texas*. The large numbers of individual stems present and their occurrence through a rather extensive area of the rockhouse argues against any type of recent human interven-

FIG. 1. Rockhouse habitat in Parker Co., Texas with large number of individuals of *Arisaema triphyllum* in the foreground (photo by R.J. O'Kennon).

tion (e.g., transplantation). Observation of the population over two growing seasons revealed that relatively few plants produce inflorescences (roughly one in 100 during the first week of April), even fewer produce fruits (during one season only three individuals were observed with mature fruits), and most reproduction is probably by vegetation means. At the site, digging indicated that rhizomes/underground stolons could be traced between different stems signifying vegetative expansion of the population. Additionally, several transplanted plants produced offsets (traceable to the original plant) the following spring approximately 40–50 cm from the parent plants. It thus seems clear that the plants are reproducing vegetatively, and that the number of genetically different individuals probably can be determined only by molecular analyses. The apparent lack of extensive sexual reproduction is interesting in light of Kral's (1966) observation that other relict species in East Texas were also apparently reproducing predominantly via vegetative means. The disjunction between the western Parker County site and the nearest known East Texas location (Henderson County) is approximately 140 miles (225 kilometers). The occurrence of this species in the West Cross Timbers is quite unexpected given its preference for low or moist woods. However, the special microclimate (particularly reduced evapotranspiration and persistent substrate moisture) apparently has allowed the long term survival of this mesic species in an otherwise rather inhospitable macroenvironment.

The taxonomy of *Arisaema triphyllum* is controversial. Detailed study of these extremely variable plants led Huttleston (1949, 1981, 1984) to conclude that the variation seen in the species was best represented by recognizing a single species with four subspecies; he indicated that "...plants of the four subspecies are very distinctive and readily identified, at least in living condition. Since many of the key characteristics...are obscured or lost during drying, it is not always possible to identify herbarium specimens to subspecies." At the other taxonomic extreme, because "much overlap occurs in expression of the characteristics supposedly defining infraspecific taxa," because numerous intermediate forms exist, and because the ranges of the subspecies overlap, Thompson (2000) recently recognized a single variable species without infraspecific taxa. Thus, depending upon one's treatment of the variation present, the disjunct Parker County population would be either *Arisaema triphyllum* (no subspecies recognized) or *A. triphyllum* subsp. *triphyllum*. In a forthcoming flora of East Texas, we are treating the taxon as *A. triphyllum* subsp. *triphyllum*.

As discussed by Kral (1966), MacRoberts and MacRoberts (1997), and others, Texas has numerous plant occurrences which represent relicts of past climatic conditions. Further, from the study of Texas bogs (e.g., Potzger & Tharp 1954; Bryant 1977; Holloway & Bryant 1984; Bryant & Holloway 1985) and from knowledge of modern day plant distributions (e.g., Turner et al. 2003), it is clear

FIG. 2. Closeup of *Arisaema triphyllum* (photo by R.J. O'Kennon).

that Texas vegetation was profoundly influenced by the climatic change associated with glaciation, even though actual glaciers were hundreds of miles to the north of Texas. The Parker County occurrence of *Arisaema triphyllum* thus probably represents an "Ice Age holdover" (MacRoberts & MacRoberts 1997) from a colder and wetter period of the Pleistocene when vegetational areas were shifted considerably to the south and west. It is known, for example, that at 15,000 years before present, the mean annual air temperature of Texas was 5° C less than at present, conditions were moister, and there was a more widespread forest mosaic over most of Texas (Bryant 1977; Stahle & Cleaveland 1995). Other modern day reflections of such past conditions can be seen in the many species and genera typical of East Texas showing up in isolated disjunct pockets on the Edwards Plateau (e.g. *Hamamelis virginiana* L., witch-hazel) as well as many other interesting disjunct species and communities (Palmer 1920; Diggs 2002).

While rare in Texas, rockhouses do provide an interesting window into biogeographic history. As noted by Farrar (1998), the disjunct occurrences of plant species in rockhouses "document, as clearly as do fossils, a record of changing climate and vegetation." When this phenomenon is taken together with the study of bogs, and an understanding of other current day plant distributions, the impact of glacial history on the vegetation of Texas becomes increasingly understandable.

If there was ever a dust jacket that made you want to open up a book it is the one on this book. It pictures the glorious bald cypress (*Taxodium distichum*) with its stunning buttress-like trunks, reflecting on the Neches River. This book is a reflection of Geraldine Watson and her love of nature, East Texas, the Neches River, and the Big Thicket. "The book is a series of essays about a river and its environment, and the kind of people such environs produce, which includes myself."

Geraldine Watson, botanist, plant ecologist, naturalist, and conservationist, was one of several people instrumental in raising attention and serving as a national conscience to save at least some thing of the Big Thicket in East Texas. Thank you Geraldine for your hard work and for giving us a book full of history and memories! Thanks to the T.L.L. Temple Foundation for a generous grant to help publish the book and to the Big Thicket Association for their assistance —*Barney Lipscomb, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX 76102-4060, U.S.A., barney@brit.org.*

William Dean Reese, 'Bill' to family members and his many friends, died, age 73, on 4 February 2002 in Lafayette, Louisiana after a short battle with cancer.

Bill was born in Baltimore, Maryland on 10 September 1928. His formative years were spent on a dairy farm, and as a result he always considered himself a 'farm boy at heart.' Perhaps as a result of his experiences on the farm Bill had a practical approach to life and an unquenchable appreciation for nature. This view never left him. Bill strived to pass this view on to his children and grandchildren. Realizing that his children and grandchildren would never experience the joys of farm life he decided to record memories of his years on the farm, primarily for their benefit. These memories were privately published in 1997 as *Lone Hickory. Reminiscences from the Reese Farm at Gwynnbrook, Maryland, 1930s-1940s*, with corrections made in 1998.

Bill enrolled in the University of Maryland in 1945, but his undergraduate studies were interrupted by two tours in the United States Army. In 1946–48, as a member of the Signal Corps, he was stationed in the Philippines; between 1950–51 he was a cook in Fort Hood, Texas. Bill's great love of cooking (and eating!) good food was perhaps initiated by this experience. In 1953 Bill was graduated from the University of Maryland with a B.S. in Botany. It was during his undergraduate studies that Bill's interest in bryophytes was piqued. In one of his biological science laboratories Bill observed the release of living antherozoids from moss antheridia, an observation that led to his second bryological publication, *On observing bryophyte antherozoids* (Bryologist 58:335–336. 1955). In the Fall of 1953 Bill began graduate studies in bryology at Florida State University under Dr. Ruth S. Breen, graduating with an M.S. in Botany in 1955 and a Ph.D. in Botany in 1957.

Upon graduation, Bill was offered and accepted an appointment as Assistant Professor of Biology at The University of Southwestern Louisiana (now The University of Louisiana at Lafayette). He remained at this university throughout his 30-year professional career, advancing to Associate Professor (1962) and Professor (1966). Bill was an outstanding teacher and served as primary advisor to 11 graduate students. In 1970 he was named *University of Southwest Louisi-*

SIDA 20(3): 1335–1338. 2003

WILLIAM DEAN REESE
(1928–2002)

ana Foundation Distinguished Professor. Upon his retirement in 1987 the University appointed him *Edwin L. Stephens Honor Professor Emeritus*, an appointment he held until his death. In addition to his teaching responsibilities, Bill served the University and Biology Department as an able administrator: Chairman of the Biology Department (1974–77) and Department Head (1981–86).

Bill was a towering figure in American bryology. His primary interest centered on the tropical/subtropical family Calymperaceae. His studies on this family began with his Ph.D. dissertation and continued for the remainder of his life. Never tiring of these mosses, he delved into their systematics and phylogeny, the evolution and functional morphology of their asexual reproduction, and the evolution of their niche specificity. At his death he left an incomplete manuscript, *Fertility in Calymperaceae: Calymperes, Mitthyridium and Syrrhopodon*. Bill's interest in bryology, however, was not limited to the Calymeraceae. He was also a superb floristic bryologist with particular interest in the mosses of the southern United States. His book *Mosses of the Gulf Coast*, which treats the species from the Rio Grande (southern Texas) to the Apalachicola River (western Florida), is the standard floristic work for that region.

Throughout his career, Bill had a total of 154 bryological publications.

Bill was a consummate botanist. Although his principal interests lay in bryology, Bill was an acknowledged authority on the taxonomy of vascular plants. He took great delight in showing visitors the many interesting native flowering plants he had transplanted around his home. His professional interest in vascular plants led to the publication of several papers as well as the book *Acadiana Flora. Native and Naturalized Woody Plants of South-Central Louisiana*, completed with his long-time colleague at the university, Garrie Landry. At the time of his death he was working on another book., *Mamou: Acadian Folklore, Natural History, and Botany of Erythrina herbacea L.*, with Charles Allen, a former graduate student. Away from botany, he had considerable knowledge of fungi, particularly the basidiomycetes, and was an avid ornithologist, delighting in pointing out to visitors the many spectacular birds native to southern Louisiana.

Bill and a colleague, John Thieret, were the first (and only) botanists to complete an exhaustive survey of the vascular flora of the five 'salt domes' [Bell Island, Cote Blanche Island (accessible only by boat), Weeks Island, Avery Island, and Jefferson Island] located along the Louisiana coast. The results of this survey were published as *Botanical Study of the Five Islands of Louisiana*. Bill was immensely proud of his part in this exploratory work and continued to revisit the accessible areas long after the survey was completed.

Bill found great enjoyment in field work. Collecting specimens of bryophytes and vascular plants was one of his great pleasures and greatly enhanced his research. In addition to collecting extensively in North America he also participated in expeditions to Mexico, the Amazon Basin in South America, the

West Indies, Australia, and China. His earliest recorded collection, a specimen of *Quercus falcata* Michx., was made just outside Tallahassee, Flordia in August 1955, and his last identified collection (*Reese 18,593*), *Pseudoleskeella tectorum* (Brid.) Kindb., was made in Otero County, New Mexico on 15 June 2000. These collections (numbering about 35,000 specimens) are now in MO and are available for study. Eventually the collections will be intercalated in the Crosby Bryophyte Herbarium (MO). Record books and journals are also on file at MO.

In addition to his duties as teacher, researcher and administrator, Bill was an exceptional editor. Although he was exacting and had little patience with foolishness, he balanced his criticisms with encouragement and insightful comments, a reflection of his quiet and even nature. When a manuscript was returned by Bill one could be certain that it was considerably improved, regardless of how many times it had been edited previously. Bill was twice Editor of The Bryologist (1970–74; 1988–1995), and Associate Editor of The Bryologist (1977–1980), and an editor for and an unwavering supporter of the *Bryophyte Flora of North America* project, for which before his death he completed manuscripts in the Brachytheciaceae, Calymperaceae, Cryphaeaceae, Hypnaceae, Leucodontaceae, Leucophanaceae, Meteoriaceae, Pterobryaceae, Ptychomitriaceae, Racopilaceae, and Splachnobryaceae.

Bill served The American Bryological and Lichenological Society as Secretary-Treasurer (1969–1970), Vice-President (1977–1979), and President (1979–1981). In addition, Bill was a member of the American Association for the Advancement of Science, Association of Southeastern Biologists, British Bryological Society, International Association of Bryologists, International Association for Plant Taxonomy, Nordisk Bryologisk Forening, Sociedad Latinamericano de Briología, Society of the Sigma Xi, and a charter member of the Hedwigian Society (Missouri Botanical Garden). In 1988 he was appointed a Research Associate by the Missouri Botanical Garden.

Bill is survived by his wife, Lorelle, two daughters, Jean Harvill and Christine Proctor, twin sons, David and William, and five grandsons.

Bryology has lost one of its pre-eminent students, his family a loving and wonderful husband, father and grandfather, and those of us who knew him well, a faithful and loyal friend.

The tribute to Bill published in Bryologist 105(4):625–634. 2002 [2003] includes a list of taxa associated with Bill, and a bibliography of his botanical publications.

BOOK REVIEW

JOHN F. NUNN. 2002. **Ancient Egyptian Medicine.** (ISBN 0-8061-3504-2, pbk.) (Orders: University of Oklahoma Press, 4100 28th Avenue, Norman, OK 73069-8218; www.oupress.com, 405-307-9048 fax). $29.95, 240 pp, 45 b/w illustrations, 32 tables, 1 map, 7" × 10".

When one considers the topic of Egyptology, the thoughts which arise are sure to concern themselves with the elaborate tombs and pyramids that can be found in any picture guide to the Ancient Egyptians; although this is an important facet of study, it allows other, more subtle aspects of the culture to be ignored. Within the 240 pages of his work, John Nunn presents a comprehensive, yet detailed, account of one of the lesser studied topics within Ancient Egyptian culture: medicine. Nunn carries the reader from a brief background of the aspects of Egyptian culture influencing their medical practice to studies of their healers, drug therapies and to their more specialized branches. Approaching the subject as a retired anesthesiologist as well as an Egyptologist, Nunn is in a unique position to act as an authority on the merging of these two subjects.

The book begins with a brief geographical and historical placement of the Ancient Egyptians, establishing the "unique environment in which their medical practice could be developed and recorded" by means of discussion of methods of food production, nutritional state, life expectancy, writing, etc. The primary concern of this first chapter is to set the stage and the background for the reader to be able to follow the remainder of the book. After establishing that the culture had the leisure to engage in activities other than defense and food production, the discussion moves to the primary source of the claims Nunn makes, the medical papyri.

Through an extensive compilation and investigation of various surviving medical texts written on papyrus (*Cyperus papyrus*), Nunn reaches his conclusions about the medical practice of the Ancient Egyptians while also acknowledging the difficulties of translation. Other important sources of information used in the investigation include human remains and artistic renditions of the disease state. In particular, the embalming techniques and environmental conditions (a dry and hot climate) of the region acted to preserve the human remains in excellent detail (causing them to desiccate faster than they would putrefy). There is a conscious effort made to avoid the pitfalls of validating the past in terms of modern concepts, while yet highlighting the fact that certain medical procedures practices by the Egyptians are in fact up to modern standards.

The remaining chapters carry the topics mentioned at the beginning to deeper levels; for example, carrying the topic of the patterns of disease, to intricate discussions about such things as parasitic, viral and bacterial diseases, deformities, and ageing processes. Furthermore the book is littered with documented studies regarding each topic, thus also serving as a reference to further reading on the particular topics. The readers will chuckle as they read the various treatments for disease states, such as those found within the chapter on specialized medical branches. Regarding sex determination during pregnancy: "Emmer (*bedet*) and barley (*it*), the lady should moisten with her urine every day, like dates and like sand in two bags. If they all grow, she will bear a child. If the barley grows, it means a male. If the emmer grows, it means a female. If they do not grow, she will not bear a child." The interesting aspect about this case is the unusual findings Nunn documents of studies done in 1963 by Ghalioungui et al., testing the treatment.

The format of the book is quite easy to follow, it increases in complexity as the reader's background is established, and where a subject is touched upon that will later be clarified, the location is specified. Although there are no color illustrations, those few well-chosen diagrams clarify the concepts dealt with in the text. The many tables are quite comprehensive and include those dealing with herbal remedies of certain, less certain and uncertain origin, as well as 29 others. While it is unlikely

that the majority of readers will be able to follow the entire book with complete understanding, the discussions are all sufficiently in-depth to maintain a specialist's interest while also maintaining that of a reader new to the field.

While the information contained within this 2002 work is merely a reprint of the 1996 cloth publication, the improved presentation of the material makes it less liable to being overlooked The book manages to bridge a gap in its particular field, building and improving upon other publications which have at best been incomplete and muddling. Nunn has presented a concise and well-rounded approach to the study of medicine in Ancient Egyptian culture, which will leave both the merely interested reader and the avid scholar, fully satisfied.—*Tiana Francesca Franklin, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX, 76102,4060, U.S.A., tianaff@hotmail.com.*

NEW BOOKS

David Pimentel (Editor). 2002. **Biological Invasions: Economic and Environmental Costs of Alien Plant, Animal, and Microbe Species.** (ISBN 0-8493-0836-4, hbk.). CRC Press LLC, 2000 N.W. Corporate Blvd., PO Box 31225, Boca Raton, FL 33431, U.S.A. (Orders: 800-272-7737, fax 800-374-3401; Canada & International 561-994-0555, fax 561-989-8732, www.crcpress.com). Price not given, 369 pp., graphs/figs., 7" × 10".

Forty-five contributors provide detailed information on components of the invasive-species problem from six continents. The book is divided into nine sections: **I** Introduction; **II** Australia; **III** Brazil; **IV** British Isles; **V** India; **VI** New Zealand; **VII** South Africa; **VIII** United States; **IX** World Overview. The book is informative and will serve "scientists, policymakers, and the public on the seriousness of non-native species invasions, which can cause extinctions and significant costs to the environment, economy, and public health."

Eric T. Jones, Rebecca J. McLain, and James Weigand (Editors). 2002. **Nontimber Forest Products in the United States.** (ISBN 0-7006-1165-7, pbk.). University Press of Kansas, 2501 West 15th Street, Lawrence, KS 66049, U.S.A. (Orders: 785-864-4154, fax 785-864-4586, www.kansaspress.ku.edu). $29.95, 445 pp., 2 figures, 6" × 9".

From press release: "*Nontimber Forest Products in the United States* provides the first comprehensive examination of these abundant resources throughout the United States, illustrating nontimber forest products' diverse importance, describing the people who harvest them, and outlining the steps that are being taken to ensure access to them."

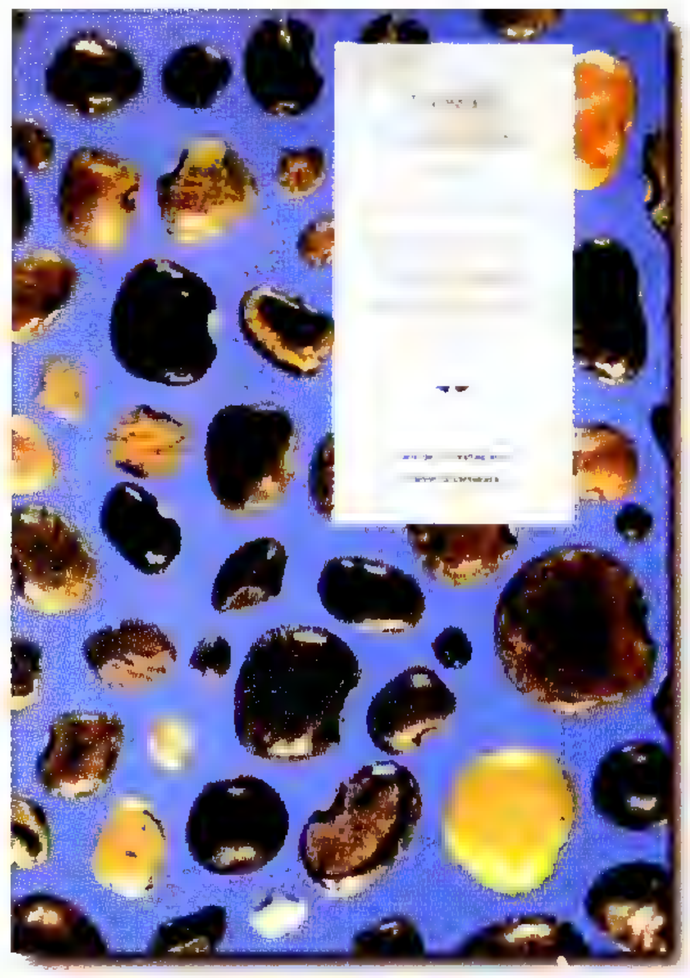
Duane A. Smith. 2002. **Mesa Verde National Park: Shadows of the Centuries, Revised Edition.** (ISBN 0-87081-684-5, pbk.). University Press Colorado, 5589 Araphoe Road, Suite 206C, Boulder, CO 80303, U.S.A. (Orders: 720-406-8849, fax 720-406-3443). $14.95, 272 pp., 63 b/w photos, 2 maps, 6" × 9".

THE RUPERT BARNEBY AWARD

The New York Botanical Garden is pleased to announce that Jason Alexander, currently a graduate student in the Department of Botany & Plant Pathology, Oregon State University, is the recipient of the Rupert Barneby Award for the year 2003. Mr. Alexander will be studying the systematics of various species of *Astragalus* in the western United States.

The New York Botanical Garden now invites applications for the Rupert Barneby Award for the year 2004. The award of US$ 1,000.00 is to assist researchers to visit The New York Botanical Garden to study the rich collection of Leguminosae. Anyone interested in applying for the award should submit their curriculum vitae, a detailed letter describing the project for which the award is sought, and the names of 2-3 referees. Travel to the NYBG should be planned for sometime in the year 2004. The application should be addressed to Dr. James L. Luteyn, Institute of Systematic Botany, The New York Botanical Garden, 200th Street and Kazimiroff Blvd., Bronx, NY 10458-5126 USA, and received no later than December 1, 2003. Announcement of the recipient will be made by December 15.

Anyone interested in making a contribution to THE RUPERT BARNEBY FUND IN LEGUME SYSTEMATICS, which supports this award, may send their check, payable to The New York Botanical Garden, to Dr. Luteyn.



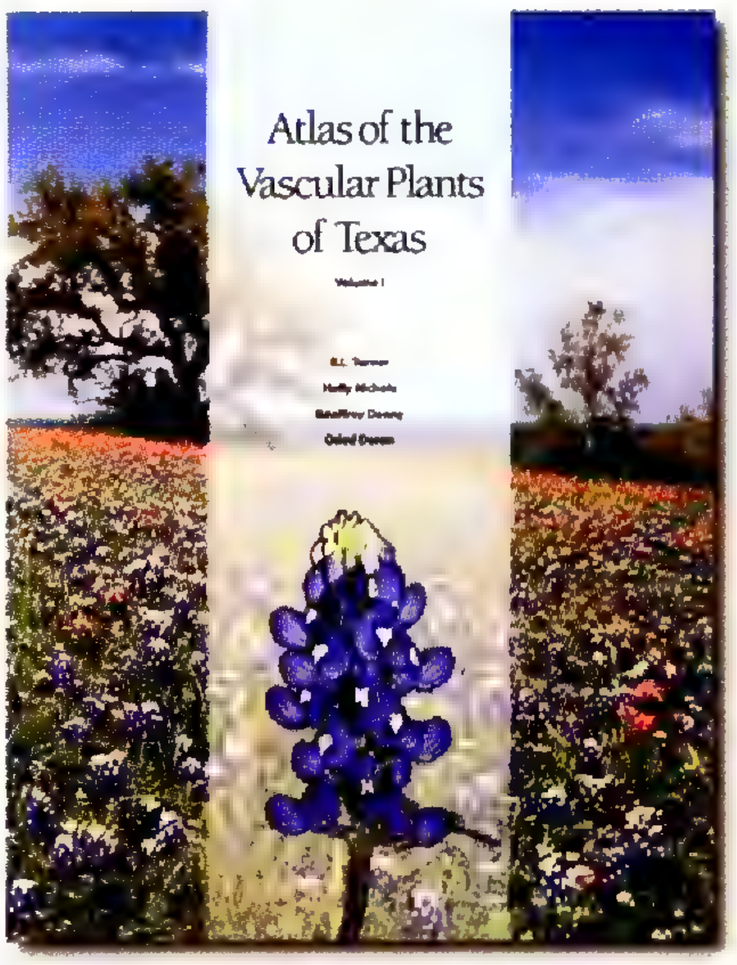
THE DELZIE DEMAREE TRAVEL AWARD

Graduate students in plant systematics are eligible to apply for the Delzie Demaree Travel Award, a $250.00 stipend to help defray expenses related to attendance at the Missouri Botanical Garden 50th Annual Systematics Symposium (10–11 Oct 2003). The 2003 symposium: Species Reconsidered: Consequences for Biodiversity and Evolution.

The application should include a letter from the applicant telling how symposium attendance will benefit his/her graduate work and letter of recommendation sent by the major professor. Please mail letters of application to: Dr. Donna M.E. Ware, Herbarium, Biology Department, The College of William and Mary, Williamsburg, VA 23185, U.S.A.

Anyone interested in making a contribution to Delzie Demaree Endowment Fund, which supports the travel award, may send their check, payable to Botanical Research Institute of Texas, to Barney Lipscomb, 509 Pecan Street, Fort Worth, TX 76102-4060, U.S.A. Thank you.

This lavishly illustrated monograph is the most comprehensive botanical treatment of beans to date. It begins with a brief history about the former taxonomical treatments of the genus, and goes on with the taxonomical criteria and a presentation about discriminant characteristics. It presents a full description of each section and species, its distribution and habitat, relationships with other species, uses and potentially useful traits, and historical notes. Color pictures, line drawings, and distribution maps lead easily to the right identification of each species.



Taxonomy, Distribution, and Ecology of the Genus Phaseolus (Leguminosae–Papilionoideae) in North America, Mexico and Central America

The *Atlas of Texas* covers about 6000 taxa. This is the result of 54 years of herbarium and fieldwork by B.L. Turner, beginning in 1948 at Sul Ross State University, Alpine, Texas. In short, the senior author has examined personally, touched, or "pored over" an estimated several hundred thousand sheets in the preparation of the forthcoming Atlas volumes. Contents include an introduction, atlas of Texas plants arranged alphabetically by family, by genus, by species, and an index.

Table of Contents

SYSTEMATICS

Castilleja albobarbata sp. nov. (Orobanchaceae) from Sierras Manantlán and Cacoma, Jalisco, Mexico
Hugh H. Iltis, Guy L. Nesom, and J. Mark Egger 1343

Ipomoea tacambarensis (Convolvulaceae), especie nueva del estado de Michoacán, México
Eleazar Carranza González 1351

Portulaca matthewsii (Portulacaceae), a new species from the "Sierra Gorda" Biosphere Reserve, Querétaro, Mexico
Gilberto Ocampo Acosta 1357

A new species of **Chaptalia** (Asteraceae: Mutiseae) from Mexico and rediscovery of **Chaptalia mexicana**
Leticia Cabrera R. and Guy L. Nesom 1363

Taxonomy of the Polemoniaceae: the subfamilies and tribes
Verne Grant 1371

A synopsis of **Machaeranthera** (Asteraceae: Astereae), with recognition of segregate genera
David R. Morgan and Ronald L. Hartman 1387

A new species of **Arida** (**Machaeranthera** sect. **Arida**—Asteraceae: Astereae) from Trans-Pecos, Texas
B.L. Turner and Guy L. Nesom 1417

Further additions to the genus **Ardisia** subgenus **Graphardisia** (Myrsinaceae)
Jon M. Ricketson and John J. Pipoly III 1423

A revision of the **Psidium salutare** complex (Myrtaceae)
Leslie R. Landrum 1449

Revision and typification of some species of **Ixora** (Rubiaceae) from Central and Southern Brazil
Piero G. Delprete 1471

A new section of **Baccharis** (Asteraceae: Astereae), and notes on allied taxa
Daniel A. Giuliano and Guy L. Nesom 1481

Two new combinations in Bolivian **Gentianella** (Gentianaceae)
James S. Pringle 1485

Botanical summary of a lowland ultrabasic flora in Papua New Guinea
W. Takeuchi 1491

New combination in **Eurybia** (Asteraceae: Astereae) from North America
Luc Brouillet 1561

A new species of **Brazoria** (Lamiaceae) from the central mineral region of Texas
MATT W. TURNER 1565

Two new species of **Liatris** series **Graminifoliae** (Asteraceae: Eupatorieae) from the southeastern United States
ROBERT KRAL and GUY L. NESOM 1573

New combinations in **Xanthisma** (Asteraceae: Astereae)
GUY L. NESOM 1585

A new species of **Solidago** (Asteraceae: Astereae) from north central Alabama
BRIAN R. KEENER and ROBERT KRAL 1589

Solidago faucibus (Asteraceae: Astereae), a new mesic forest goldenrod from the Appalachian Mountains
THOMAS F. WIEBOLDT and JOHN C. SEMPLE 1595

New names and combinations in goldenrods, **Solidago** (Asteraceae: Astereae)
JOHN C. SEMPLE 1605

Pappus variation in **Solidago** (Asteraceae: Astereae)
JENNIFER L.A. HOOD and JOHN C. SEMPLE 1617

Typification, taxonomy, and a new subspecies of **Polygonum sawatchense** (Polygonaceae) from North America
MIHAI COSTEA and FRANÇOIS J. TARDIF 1631

Typification and nomenclatural history of **Trachelospermum difforme** (Apocynaceae)
ALEXANDER KRINGS 1641

New names and new combinations in the flora of Hispaniola
HENRI ALAIN LIOGIER 1645

Glandularia verecunda (Verbenaceae): species or fruit-form?
B.L. TURNER 1647

New combination in Astereae (Asteraceae)
GUY L. NESOM and HAROLD ROBINSON 1649

DEVELOPMENT AND STRUCTURE

Anatomía comparada de la epidermis foliar en el grupo de especies **Solanum sessile**, de la sección **Geminata** (Solanaceae)
CARMEN BENÍTEZ DE ROJAS and CHIARA BERLINGIERI 1651

DOCUMENTED CHROMOSOME NUMBERS

Documented chromosome numbers. 2003: 2. Chromosome numbers of the rare Texas species, **Arida blepharophylla** and **A. mattturneri** (Asteraceae: Astereae)
A. MICHAEL POWELL 1663

FLORISTICS AND ECOLOGY

Aspectos ecológicos y estado de conservación de **Mammillaria theresae** (Cactaceae)
IRMA LORENA LÓPEZ-ENRÍQUEZ, M. SOCORRO GONZÁLEZ-ELIZONDO, MARTHA GONZÁLEZ-ELIZONDO, and JORGE ALBERTO TENA-FLORES **1665**

Type localities of vascular plants first described from Ohio
RONALD L. STUCKEY and JAMES S. PRINGLE **1677**

The east-west transition of the flora in Texas: a biogeographical analysis
MICHAEL H. MACROBERTS and BARBARA R. MACROBERTS **1693**

Rediscovery of **Tephrosia jamnagarensis** (Fabaceae), an endangered and narrow endemic plant species of Saurashtra, Gujarat, India
P.S. NAGAR, S.J. SATA, and S.J. PATHAK **1701**

Does **Polygonum patulum** (Polygonaceae) grow in North America?
MIHAI COSTEA and FRANÇOIS J. TARDIF **1707**

Polygonum aviculare subsp. **rurivagum** (Polygonaceae) in North America
MIHAI COSTEA and FRANÇOIS J. TARDIF **1709**

Uvularia (Liliaceae) in Texas
JASON R. SINGHURST, WILLIAM F. CARR, WENDY J. LEDBETTER, and WALTER C. HOLMES **1713**

Fagopyrum esculentum (Polygonaceae), new for Texas
ROBERT J. O'KENNON, CAREN MCLEMORE, and AMANDA K. NEILL **1717**

Triglochin concinna (Juncaginaceae), a new family, genus, and species for Texas
B.L. TURNER and MATT W. TURNER **1721**

Andropogon glomeratus var. **glaucopsis** (Poaceae: Andropogoneae) documented in Louisiana
DAVID J. ROSEN and JOSEPH K. WIPFF **1723**

Carex conoidea (Cyperaceae) new to Arkansas and notes on its occurrence in Arkansas and Missouri
PAUL M. MCKENZIE, TIM SMITH, and C. THEO WITSELL **1727**

Additions to the flora of Cleveland County, Arkansas: collections from Moro Bottoms Natural Area, a state-protected old-growth bottomland hardwood forest
DANNY SKOJAC, MARGARET S. DEVALL, and BERNARD R. PARRESOL **1731**

Arkansas flora: additions, reinstatements, exclusions, and re-exclusions
JAMES H. PECK **1737**

Northward range extension in Florida of the invasive fern **Lygodium microphyllum** (Lygodiaceae)
Robert W. Pemberton 1759

Muhlenbergia dubia (Poaceae) in central Texas
Geoffrey C. Denny 1763

Rotala rotundifolia (Lythraceae) new to Florida
Kathleen C. Burks, Vernon V. Vandiver, Jr., David W. Hall, and Colette C. Jacono 1765

ABSTRACT

A new species, **Castilleja albobarbata** Iltis & Nesom, is described from localities in Sierra de Manantlán and Sierra Cacoma of Jalisco, México. It differs from *C. integrifolia* primarily in features of vestiture and is geographically disjunct from the nearest populations of *C. integrifolia* by about 450 kilometers.

KEY WORDS: *Castilleja*, Orobanchaceae, Scrophulariaceae, Sierra de Manantlán, Sierra Cacoma, Jalisco, México, biogeography, rare plants

RESUMEN

Se describe una especie nueva, **Castilleja albobarbata** Iltis & Nesom, de la Sierra de Manantlán y Sierra Cacoma de Jalisco, México. Se diferencia de *C. integrifolia* principalmente por las características del indumento y está separada geográficamente unos 450 kilómetros de la población más próxima de *C. integrifolia*.

Castilleja albobarbata Iltis & Nesom, sp. nov. (**Figs. 1–3**) TYPE: MÉXICO. JALISCO: Mpio. Cuautitlán, [Sierra de Manantlán Biosphere Reserve], top of sharp crest of the Sierra de Manantlán Oriental just E of Cerro Las Capillas, along highest point of gravel road from Cerro La Cumbre to Los Jardines, 19 km due SSE of El Chante (19° 33'19" N, 104° 09' W), cliffs of basaltic sandstone conglomerate, 2800–2860 m elev., 10 Oct 1980, *H.H. Iltis 3227 with R. Guzmán-M.* (HOLOTYPE: WIS; ISOTYPES: TEX, ZEA).

Castillejae integrifoliae L.f. similis sed vestimento trichomatibus brevissimis antrorse appressis et corollarum galea albobarbata differt.

Herbaceous perennials, usually with numerous (up to 15) erect to ascending or sprawling stems originating from the common base, the stems 2–4(–7) dm tall, basally woody, simple or few-branched in the upper half; stems, leaves, and bracts eglandular, moderately to sparsely invested with short (ca. 0.05–0.1 mm long), white, flattened, antrorsely ascending-appressed hairs. Leaves yellow-green, spreading to slightly deflexed, entire, not clasping or auriculate, those of the lower stems linear to narrowly lanceolate, 25–45 mm long, 2–4 mm wide,

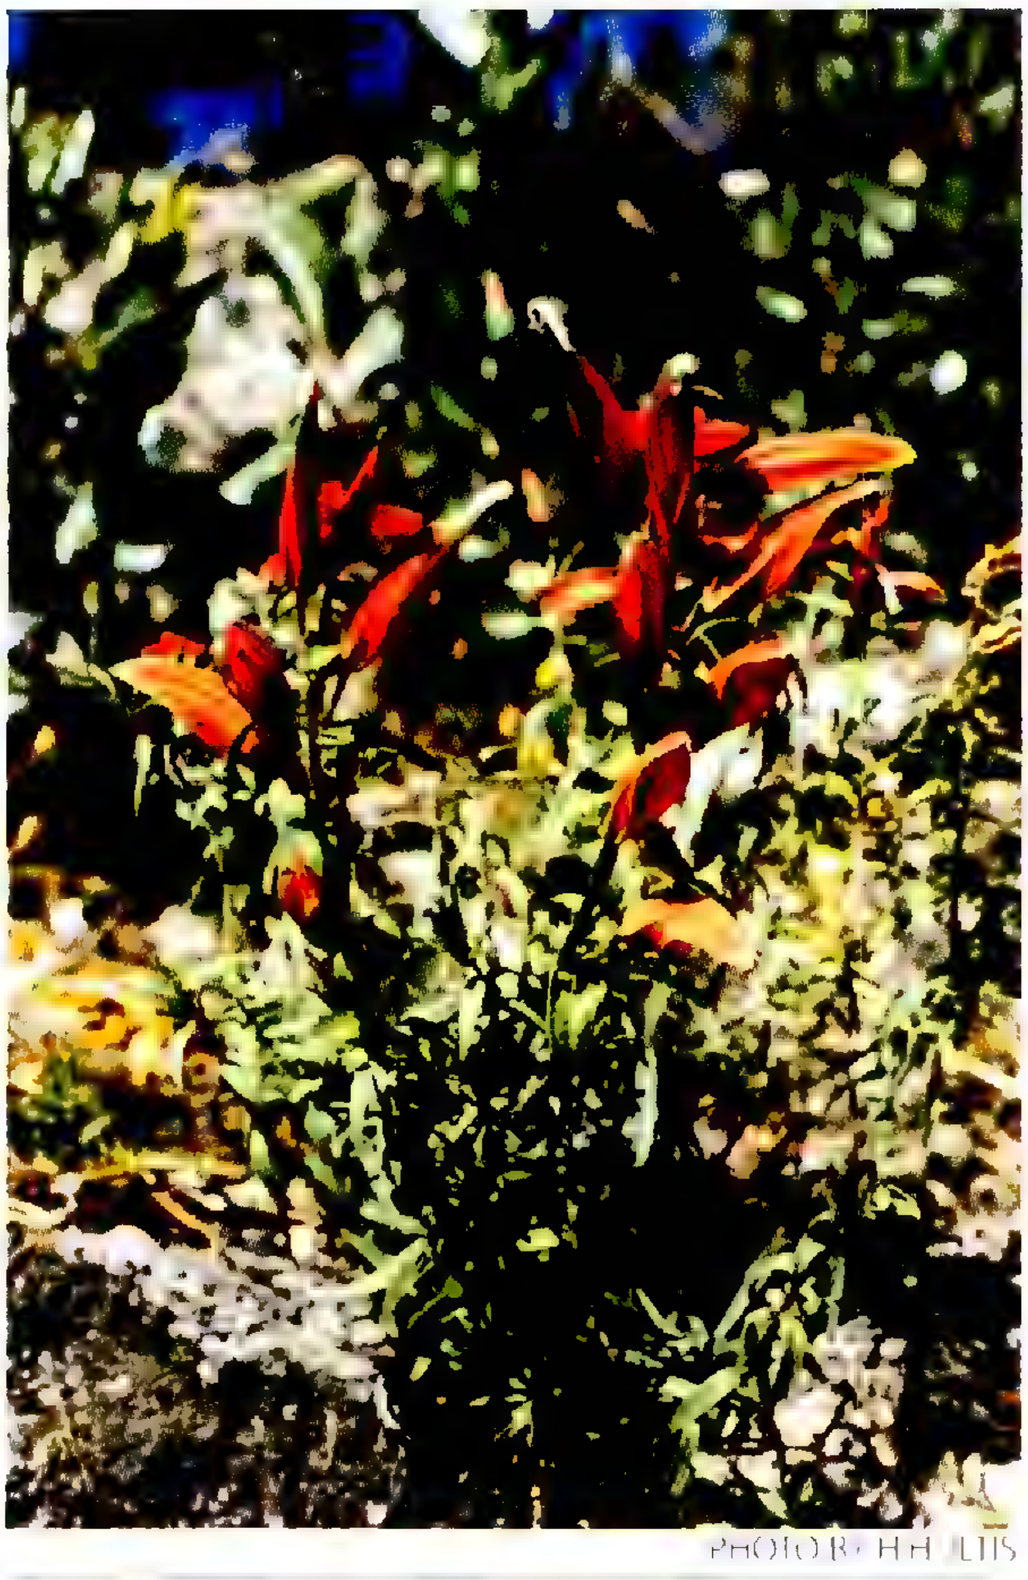

FIG. 1. Habit of *Castilleja albobarbata* (type collection).

FIG. 2. Flowers of *Castilleja albobarbata* (type collection).

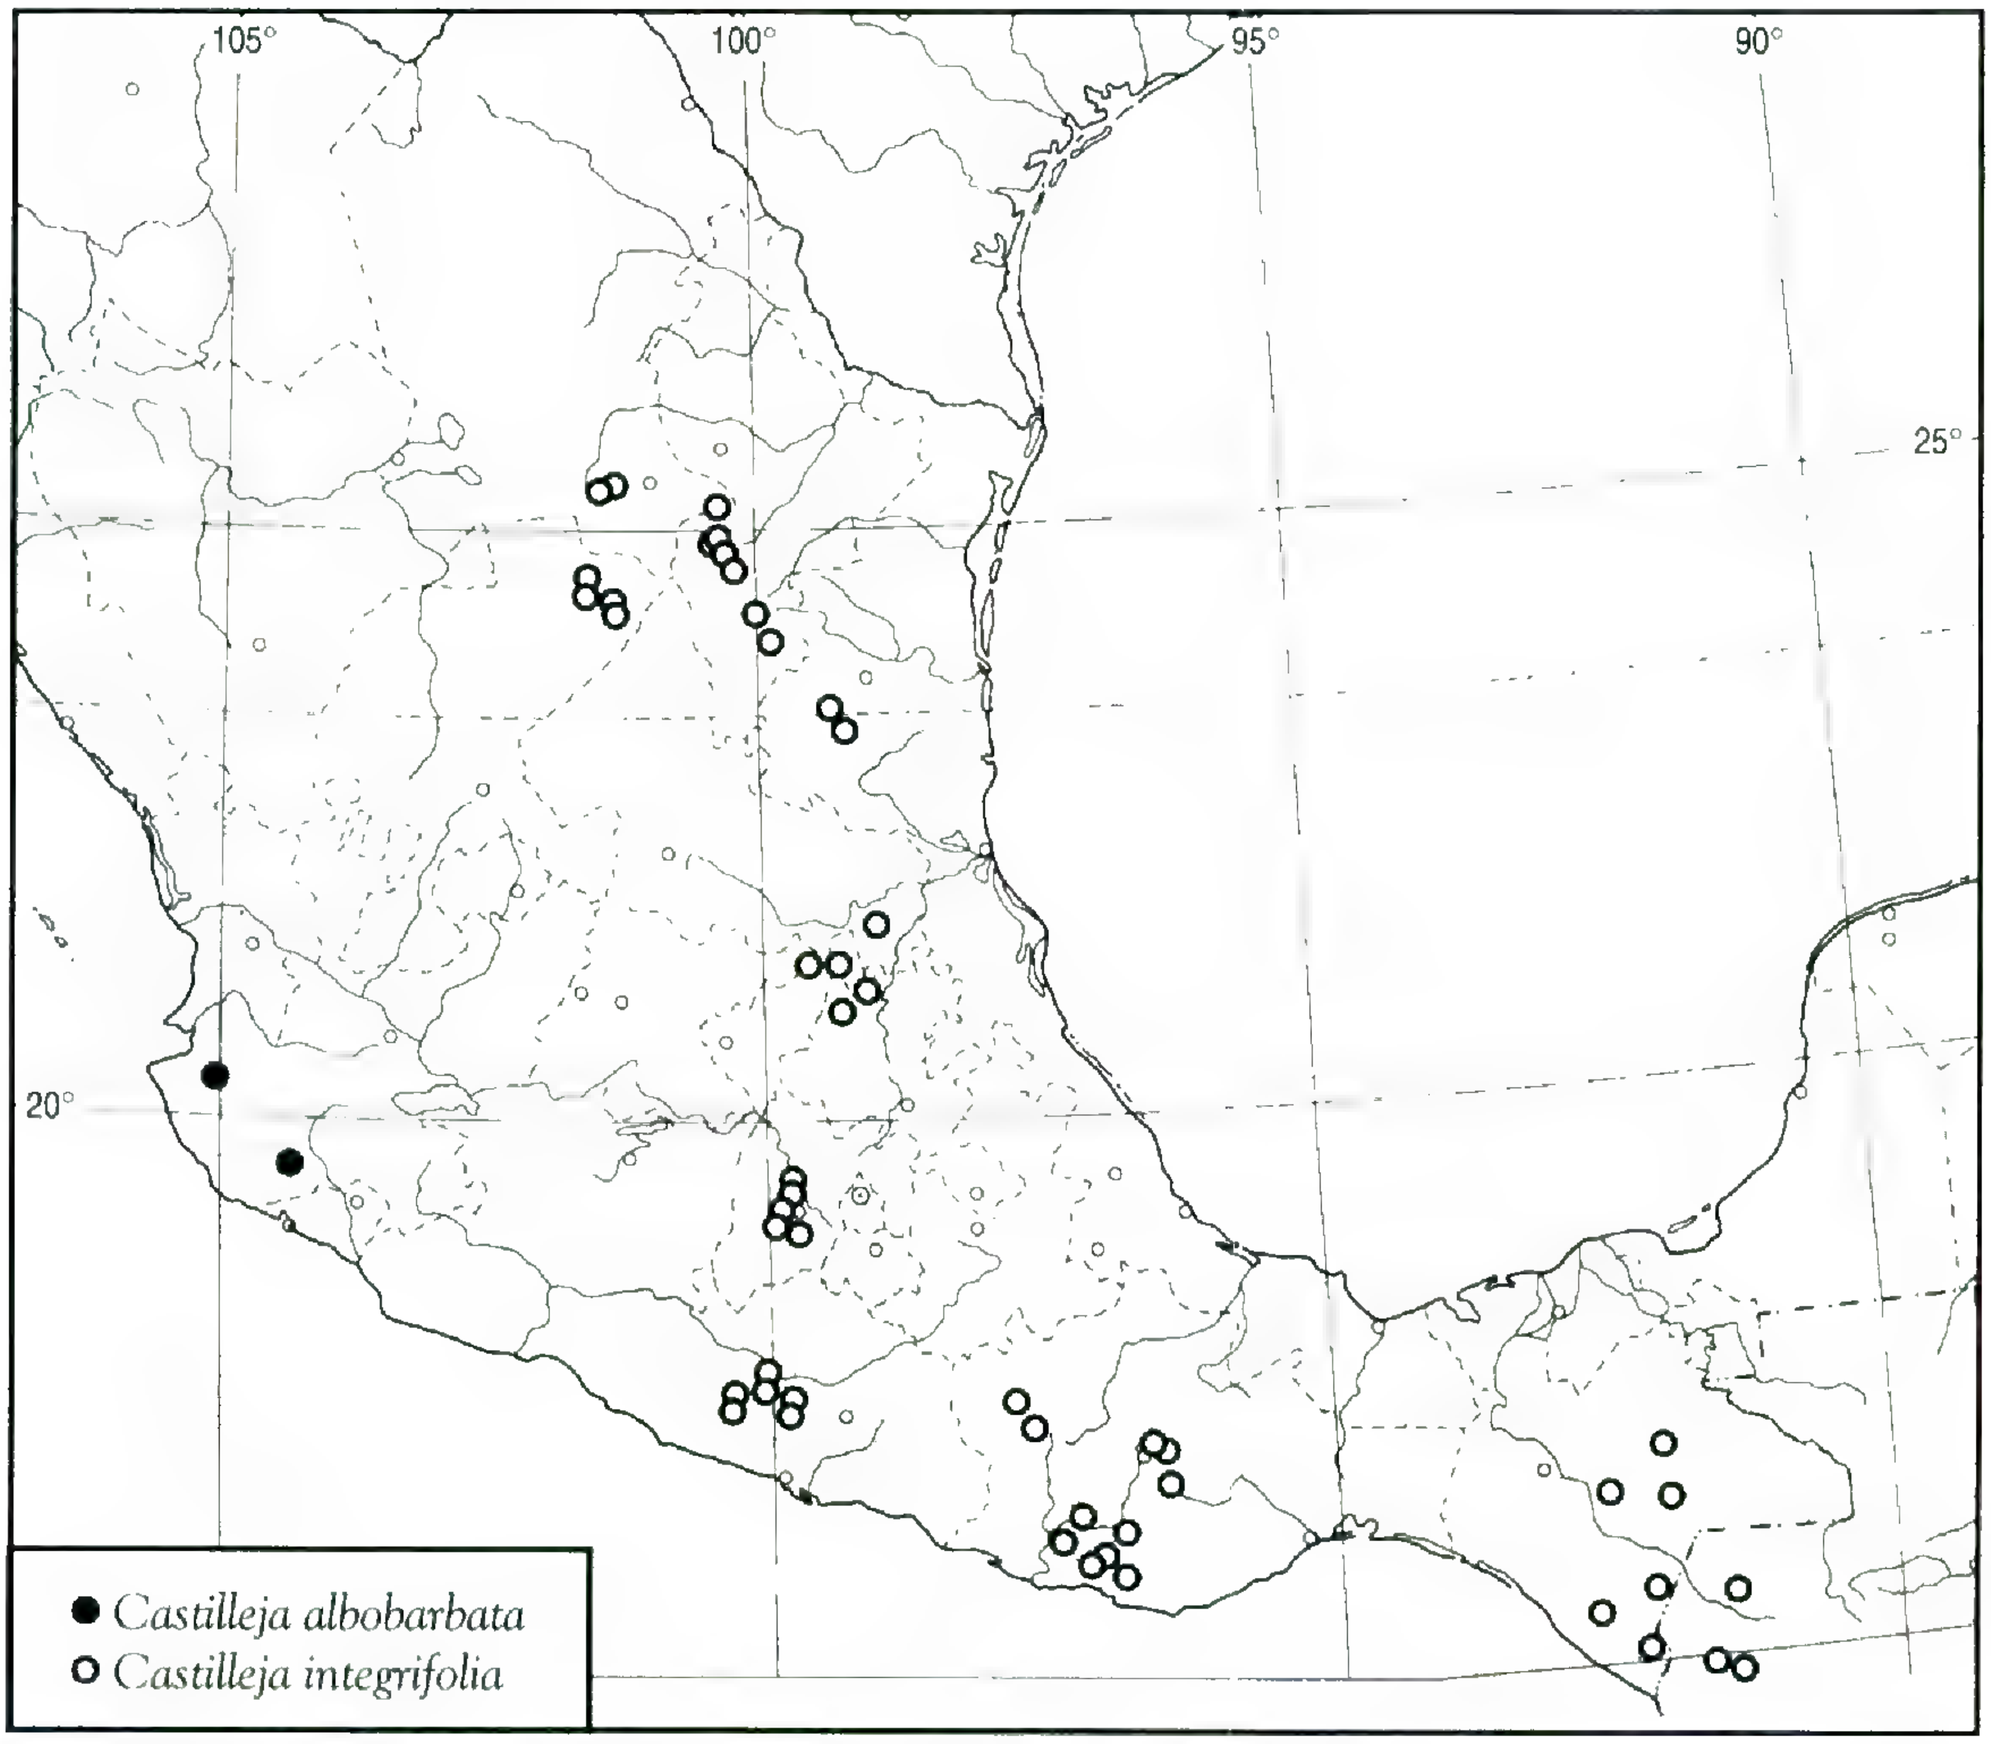

FIG. 3. Distributions of *Castilleja integrifolia* in Mexico and *C. albobarbata*. Modified after Nesom 1992.

becoming narrowly ovate-lanceolate near the inflorescence with a subclasping base and up to 6 mm wide, grading into the floral bracts. Floral bracts entire, lanceolate, 15–35 mm long, markedly enlarged from the uppermost leaves, the lower bracts completely green, the terminal persistent and conspicuous, markedly differentiated from the lower, red and obovate to widely ovate. Flowers in a racemose, somewhat secund inflorescence; pedicels 10–20 mm long, ascending; calyces 29–35 mm long, slightly gibbous abaxially, minutely hispid-strigose, brick-red with a yellow-green apical margin or sometimes yellow at the base, less commonly yellow-green throughout, the abaxial cleft 20–25 mm deep, the adaxial cleft 2–5 mm deep, the primary lobes with 2 short teeth or acute notches; corollas 40–45 mm long, the tube pale yellowish, becoming brick-red near the lower lip; the galea yellowish with red flanges, 25–27 mm long, 5/8–5/9 the length of the corolla, exserted (2–)7–15 mm from the calyx, producing a long (ca. 12 mm), densely pilose, adaxial, toothbrush-like beard of multicellular, white trichomes 2–3.5 mm long, the corolla otherwise glabrous, the lower lip composed of 3, small, thickened, greenish-yellow, incurved teeth 1–2 mm

long; stigma barely thickened, ca. 0.3 mm wide; anthers 2–2.5 mm long. Mature fruits not observed.

Additional collections examined: **MEXICO. Jalisco.** Mpio. Cuautitlán: Sierra de Manantlán, area of type collection near Cerro Las Capillas, pine woods with *Arbutus* and *Comarostaphylos*, 2800 m, 31 Aug 1986, *Cuevas 1617* (WIS) and 9 Jan 1980, *Iltis et al. 2507* (WIS, ZEA); Sierra de Manantlán, ca. 15 mi SSE of Autlán by way of Chante, rocky outcrops in cypress-pine forest, 8700 ft, 30 Jul 1949, *Wilbur and Wilbur 1989* (MICH, NY); Mpio. Cuautitlán: Sierra de Manantlán, rocky summit of canyon 3 mi W of El Guízar, 9300 ft [near type locality?], flowers red, white, and green, 23 Nov 1968, *Boutin and Brandt 2550* (MICH); Mpio. Talpa de Allende: [Sierra Cacoma], 4 km due SE of Cuale along dirt road between El Tuito turnoff (5 km N of El Tuito and 32.2 mi by road E of Mex. Hwy 200 to Minas de Zimapán) and Talpa de Allende, rare, one plant, with *Begonia* and *Prochnyanthes mexicana* atop large rock outcrop in pine forest, 20° 22' N, 105° 04' W, 1920 m (altimeter), 18 Aug 1993, *Cochrane et al. 13136* (IBUG, TEX, WIS, ZEA).

The closest relatives of *Castilleja albobarbata* are within a group of species identified as *Castilleja* subg. *Castilleja* by Holmgren (1976) and sect. *Castilleja* by Nesom (1992). These species are characterized by (1) a racemose inflorescence, (2) colored calyces but usually green floral bracts, (3) calyces with a deeply cut (anterior) abaxial cleft and a shallow (posterior) adaxial one, and (4) corollas with the galea equalling or longer than the tube. A key to most of the Mexican taxa with this character constellation (including "white-bearded *Castilleja* Iltis & Nesom ined." = *C. albobarbata*), as well as detailed discussion and distribution maps for many of them, were provided in Nesom (1992).

Within sect. *Castilleja*, *C. albobarbata* is most similar to *C. integrifolia*. This pair is distinguished among its relatives by long pedicels (10–20 mm long), a dense beard on the upper side of the galea, and loose, racemose inflorescences terminated by a cluster of colored bracts. The new species differs from *C. integrifolia* in its short, ascending-appressed (antrorsely oriented) stem hairs, compared to the cauline vestiture in *C. integrifolia* of slightly longer (mostly 0.2–0.4 mm long), deflexed (retrorsely oriented) and closely appressed hairs. The orientation of stem hairs is consistent within both species, although it may be variable in related species (e.g., *Castilleja tenuiflora* Benth.). The galea of *C. albobarbata* produces a beard similar in density and trichome length to that of *C. integrifolia*, but the beard of the new species is bright white and a striking recognition feature.

Castilleja integrifolia is a wide-ranging and variable species, distributed from the paramos of the Andes Mountains in Colombia and Venezuela, broadly through the mountainous regions of most of Central America and southern Mexico, and on northward in the Sierra Madre Oriental of northeastern Mexico as far as northern Nuevo León and Coahuila. A map of its distribution in Mexico is shown in Nesom (1992, Map 2). The type specimen was collected in Colombia (*Mutis 82*, holotype: LINN, fiche!). Within its broad range, *C. integrifolia* is fairly common in appropriate habitat and mostly consistent in its basic morphological features. Regional variants exist, however, and these are incompletely

understood. One taxon, described as *C. chiapensis* Brandegee, is based on plants from the mountains of central Chiapas, having a densely villous vestiture of golden-yellow hairs. A second form, apparently endemic to central Oaxaca and described as *C. longibracteata* Mart. & Gal., is distinguished by its broadly obovate, fimbriate-tipped apical bracts. Type material for another variant, *C. integrifolia* var. *alpigena* L. Williams from Guatemala, appears to be referable to *C. pectinata* Mart. & Gal. The range of *C. integrifolia* in Mexico most closely approaches that of *C. albobarbata* in central Guerrero and Edo. México, across a gap of about 450 kilometers. The morphological distinction between the two taxa is consistent but not great – recognition of *C. albobarbata* at specific rank emphasizes its wide geographic disjunction from *C. integrifolia*.

This taxonomic disposition is further supported by the discovery of *Castilleja albobarbata* at the far northwestern end of Sierra Cacoma, an extensive, two-parted, southeast-to-northwest oriented mountain range of the Sierra Madre del Sur that begins where Sierra de Manantlán ends at Puerto Los Mazos. This locality is about 33 kilometers southeast of Puerto Vallarta and extends the range of *C. albobarbata* more than 110 kilometers northwest of the area of the type locality at Cerro Las Capillas. It also suggests that other stations of this rare species may yet be found at high elevations in between, in that vast area of rough topography still undercollected despite many years of concerted botanical activity.

The type locality of *Castilleja albobarbata* is most remarkable floristically and ecologically (Vázquez-G. et al. 1995). Perched atop an enormous, sheer and windswept, south-facing cliff, this crest of the central section of Sierra de Manantlán forms the very edge of the Sierra Madre del Sur and reaches its highest elevation (2800–2860 meters) at Cerro Las Capillas. Below, one can see on any clear evening, far beyond the parallel ridges of ever-lower hills, the shimmering Pacific Ocean at Manzanillo, some 60 kilometers to the south. Be it due to the near continual roaring winds from off the Pacific coast or the high altitude, be it the dry crumbly sandstone conglomerate or evidence of frequent fires, the vegetation on the crest is one of an open, burnt-over pine-oak parkland (*Pinus hartwegii* Lindl. sensu lato, see comments below), the scattered trees understoried by ericaceous shrubs and tussock grass ("sacaton"), giving the appearance of a Mexican subalpine "sacatonal." The low, evergreen ericaceous scrub consists of *Pernettia prostrata* (Cav.) DC., *Vaccinium confertum* Kunth, *Comarostaphylos discolor* (Hook.) Diggs subsp. *manantlanensis* Diggs, and the remarkable diminutive *Arbutus occidentalis* McVaugh & Rosatti, the latter two here at their type locality. Amongst our scattered and rare *Castilleja* are small patches of an as yet undescribed *Alchemilla* (*A. manantlanensis* Iltis, nom. prov.) seen nowhere else, and of the robust grass tussocks of a giant *Agrostis* known apparently only from this one site. With fully 8 dm tall culms from a woody, rhizome-like base, and with many, crowded, long leaves, *A. novogaliciana*

McVaugh is unusual in other ways as well. The author himself (McVaugh 1983:42) noted that "it is quite unlike any other Mexican species of *Agrostis* and indeed may be out of place in that genus."

On the gentler, cooler, moister, north-facing slopes, a few hundred meters below the crest and less susceptible to fire, is a mixed conifer-deciduous cloud forest of *Abies religiosa* (Kunth) Schltdl. & Cham., *Pinus hartwegii*, *Cupressus lindleyi* Endl., and *Quercus* spp. In its dense understory another *Castilleja* grows in abundance, the yellow and red-flowered *C. macvaughii* N. Holmgren, a shrub to 1.5 or even 2 meters tall, strictly endemic to the high elevation cloud forests a few kilometers east and west of Cerro Las Capillas. *Castilleja macvaughii* shares its cool habitat with the recently described, more widely distributed but always local *Symplocos sousae* F. Almeda and other endemics such as *Ageratina manantlanensis* B.L. Turner. Other, more widespread *Castilleja* species, at slightly lower elevations, include *C. nervata* Eastw. and *C. pterocaulon* N. Holmgren.

Finally, even the pines at Cerro las Capillas present a taxonomic problem. "*Pinus hartwegii*" sensu lato (as noted above) is listed in Vázquez et al. (1995:106) as *P. durangensis* Martínez, according to the botanists R. Cuevas-G. and S. Carvajal-H. In the discussion, however, the local pine expert J. Pérez de la Rosa suggested it to be *P. martinezii* E. Larsen, while W.B. Critchfield identified these collections as an aberration of *P. hartwegii*. Considering the great local endemism at this locality, it may yet prove to be an undescribed local variant, and thus Critchfield correct.

The concentration of so many endemics on the slopes or at the very top of Sierra de Manantlán, some 40 species in all (Vázquez et al. 1995; Hernandez 1995:72–81), suggests that this mountain, like so many others in Mexico, acted not only as a "survivium" (refugium) of a once more extensive montane and subalpine flora during periods of glacial cooling and of its remnants in the present post-glacial warming but, in addition, because of its isolation, as an "Inselberg," an island of autochthonous speciation, even if now only a few hectares in extent.

Similarly, the Sierra Cacoma station for *Castilleja albobarbata* lies in the center of a hotbed of endemism, which though only 30 to 40 kilometers southeast to southwest of the vacation mecca of Puerto Vallarta, has until recently remained relatively uncollected. Its exploration has been facilitated by the now already deteriorating east-west gravel road that starts out (from Mexican Highway 200) 5 kilometers north of El Tuito, goes east for 52 kilometers to the *Castilleja* locality near the now abandoned Minas de Zimapán, and continues beyond for 47 kilometers to Talpa de Allende. This "brecha" Tuito-Talpa opened up since the 1960's vast, previously inaccessible, forested lands, from the subtropical northern end of Sierra El Tuito (500–1880 m) south to the higher Sierra El Cuale (1000–2300 m) north of the road, and finally to the grand, rug-

ged, isolated end of the Sierra Cacoma (with several peaks above 2600 m and one to 2740 m!). Most of the collecting evidently occurred next to the road, as with the single plant of *Castilleja*. Yet, with its rocky pine forest habitat continuing up the mountain slopes for another 1800 meters to equal the altitude of the type collection, one can predict that it may yet reveal a much larger population. And the cloud forests that probably crown the peaks also offer potentially rich scientific rewards. In any case, all along the Minas de Zimapán road, these pine to oak woods have yielded a cornucopia of rarities and recently described local endemics: *Quercus tuitensis* L.M. González and *Q. cualensis* L.M. González (González-V. 2003a, b), *Pinus jaliscana* Perez de la Rosa, *Muhlenbergia cualensis* Herrera & P. Peterson, and various novelties in the genera *Aechmea*, *Agarista*, *Aristida*, *Triniochloa*, *Pedilanthus*, *Stevia*, and *Wedelia*.

What the flora of the highest peaks may yet yield is a tantalizing question. These are, after all, extensions of Sierra de Manantlán and equivalent in altitude to that of Cerro Las Capillas (2740 vs. 2860 meters). Here is a real botanical challenge to any young botanist, for soon it may be too late. Not only are lumbering and cattle grazing expanding up the mountains to supply an ever growing Mexican population, but global warming, world-wide, is a fact botanists need to consider.

What indeed will be the fate of many of these high-altitude microcenters of biodiversity, the "Inselbergs" of evolution, these biogeographic survivia, in consequence of global warming? Surely many of these endemics and rarities would soon be pushed off their high mountain perches by a warmer climate and displaced by pine forests or even cloud forests advancing from below. But as for the large number of rarities at Las Capillas, the type locality of *Castilleja albobarbata*, their survival for the time being is assured by protection in the Core Zone of the Sierra de Manantlán Biosphere Reserve (Guzmán-M. and Iltis 1991; Halffter 1987; Vázquez et al. 1995).

ACKNOWLEDGMENTS

We are grateful to MICH for a loan of specimens, to Ted Cochrane for his excellent label data, and Rich Spellenberg for his review of the manuscript. Field work was supported by the Instituto Manantlán de Ecología y Conservación de la Biodiversidad (IMECBIO), Universidad de Guadalajara, and the National History Museums Council, E.K. and O.N. Allen Herbarium Fund, and the Davis Fund, all of the University of Wisconsin-Madison.

RESUMEN

Se describe como especie nueva y se ilustra a *Ipomoea tacambarensis* (Convolvulaceae), que se encuentra en la depresión del Balsas en el estado de Michoacán, México. Esta planta, aunque de apariencia arbustiva, es una hierba perenne que alcanza hasta 2.2 m de alto. Es similar a *Ipomoea stans* Cav., pero se distingue por su mayor tamaño (de hasta 2.2 m de alto), las hojas más grandes (de hasta de 35 cm de largo) y las inflorescencias multifloras.

PALABRAS CLAVE: *Ipomoea*, Convolvulaceae, Michoacán, México

ABSTRACT

Ipomoea tacambarensis (Convolvulaceae) from the Balsas depression in the state of Michoacán, Mexico, is described and illustrated. Although shrub-like in appearance, it does not undergo considerable secondary growth, and is thus really a robust perennial herb to 2.2 m tall. It is very similar to *Ipomoea stans* Cav., but it is distinguished by its greater size (to 2.2 m tall vs. to 1 m tall), longer leaves (to 35 cm long vs. to 11 cm long) and many flowered inflorescence (vs. flowers solitary)

KEY WORDS: *Ipomoea*, Convolvulaceae, Michoacán, México

En la vertiente hacia la Cuenca del Balsas, en el Eje Neovolcánico y dentro del municipio de Tacámbaro, Michoacán, se encontró recientemente una planta herbácea vistosa y de porte erecto que pertenece al género *Ipomoea* (Convolvulaceae). Esta especie crece en laderas y cañadas con encinares, pinares o con bosque tropical caducifolio. Comúnmente forma parte de asociaciones vegetales secundarias en pequeñas áreas dedicadas al pastoreo de ganado bovino, o en lugares con cierto grado de alteración y relativamente cercanos a caminos y poblados.

Debido al tipo de hábito tan conspicuo y por encontrarse relativamente cerca de la carretera, es raro que esta planta haya pasado desapercibida por los botánicos. Sin embargo, la zona ha sido poco explorada desde el punto de vista biológico, lo que con seguridad ha limitado el conocimiento de varios hallazgos más.

Ipomoea tacambarensis E. Carranza, sp. nov. (**Figs. 1 y 2**). TIPO: MÉXICO. MICHOACÁN. Municipio de Tacámbaro: ± 1 km al N de Paso de Morelos, cañada perturbada, con transición de bosque tropical caducifolio y bosque de encino, 1550–1600 m, 3 Sep 2002, *E. Carranza* y *V. Steinmann* 6392 (HOLOTIPO: IEB; ISOTIPOS: para distribuirse en MEXU, ENCB, XAL, EBUM).

Differt a *I. stans*, habitu ad 2.2 m alto; caule ad 3 cm diametro, ramificatione (30–)40 cm supra basin; foliis (10 -)16–30(–35) cm longis, (5–)12–24 cm latis, petiolis canaliculatis ad 4 cm longis, ad 5 mm diametro; inflorescentiis terminalibus vel axillaribus, multiflori; sepalis oblongo-ovatis, (13–)15–17 mm longis, 6–8 mm latis, aequalibus vel subaequalibus; stylo 3.5–4 cm longo.

Planta herbácea, erecta, de hasta 2.2 m de alto; tubérculo de 20 a 40 cm de largo y de 10 a 20 cm de diámetro, tallos principales 3 a 5, algo angulosos, huecos, de

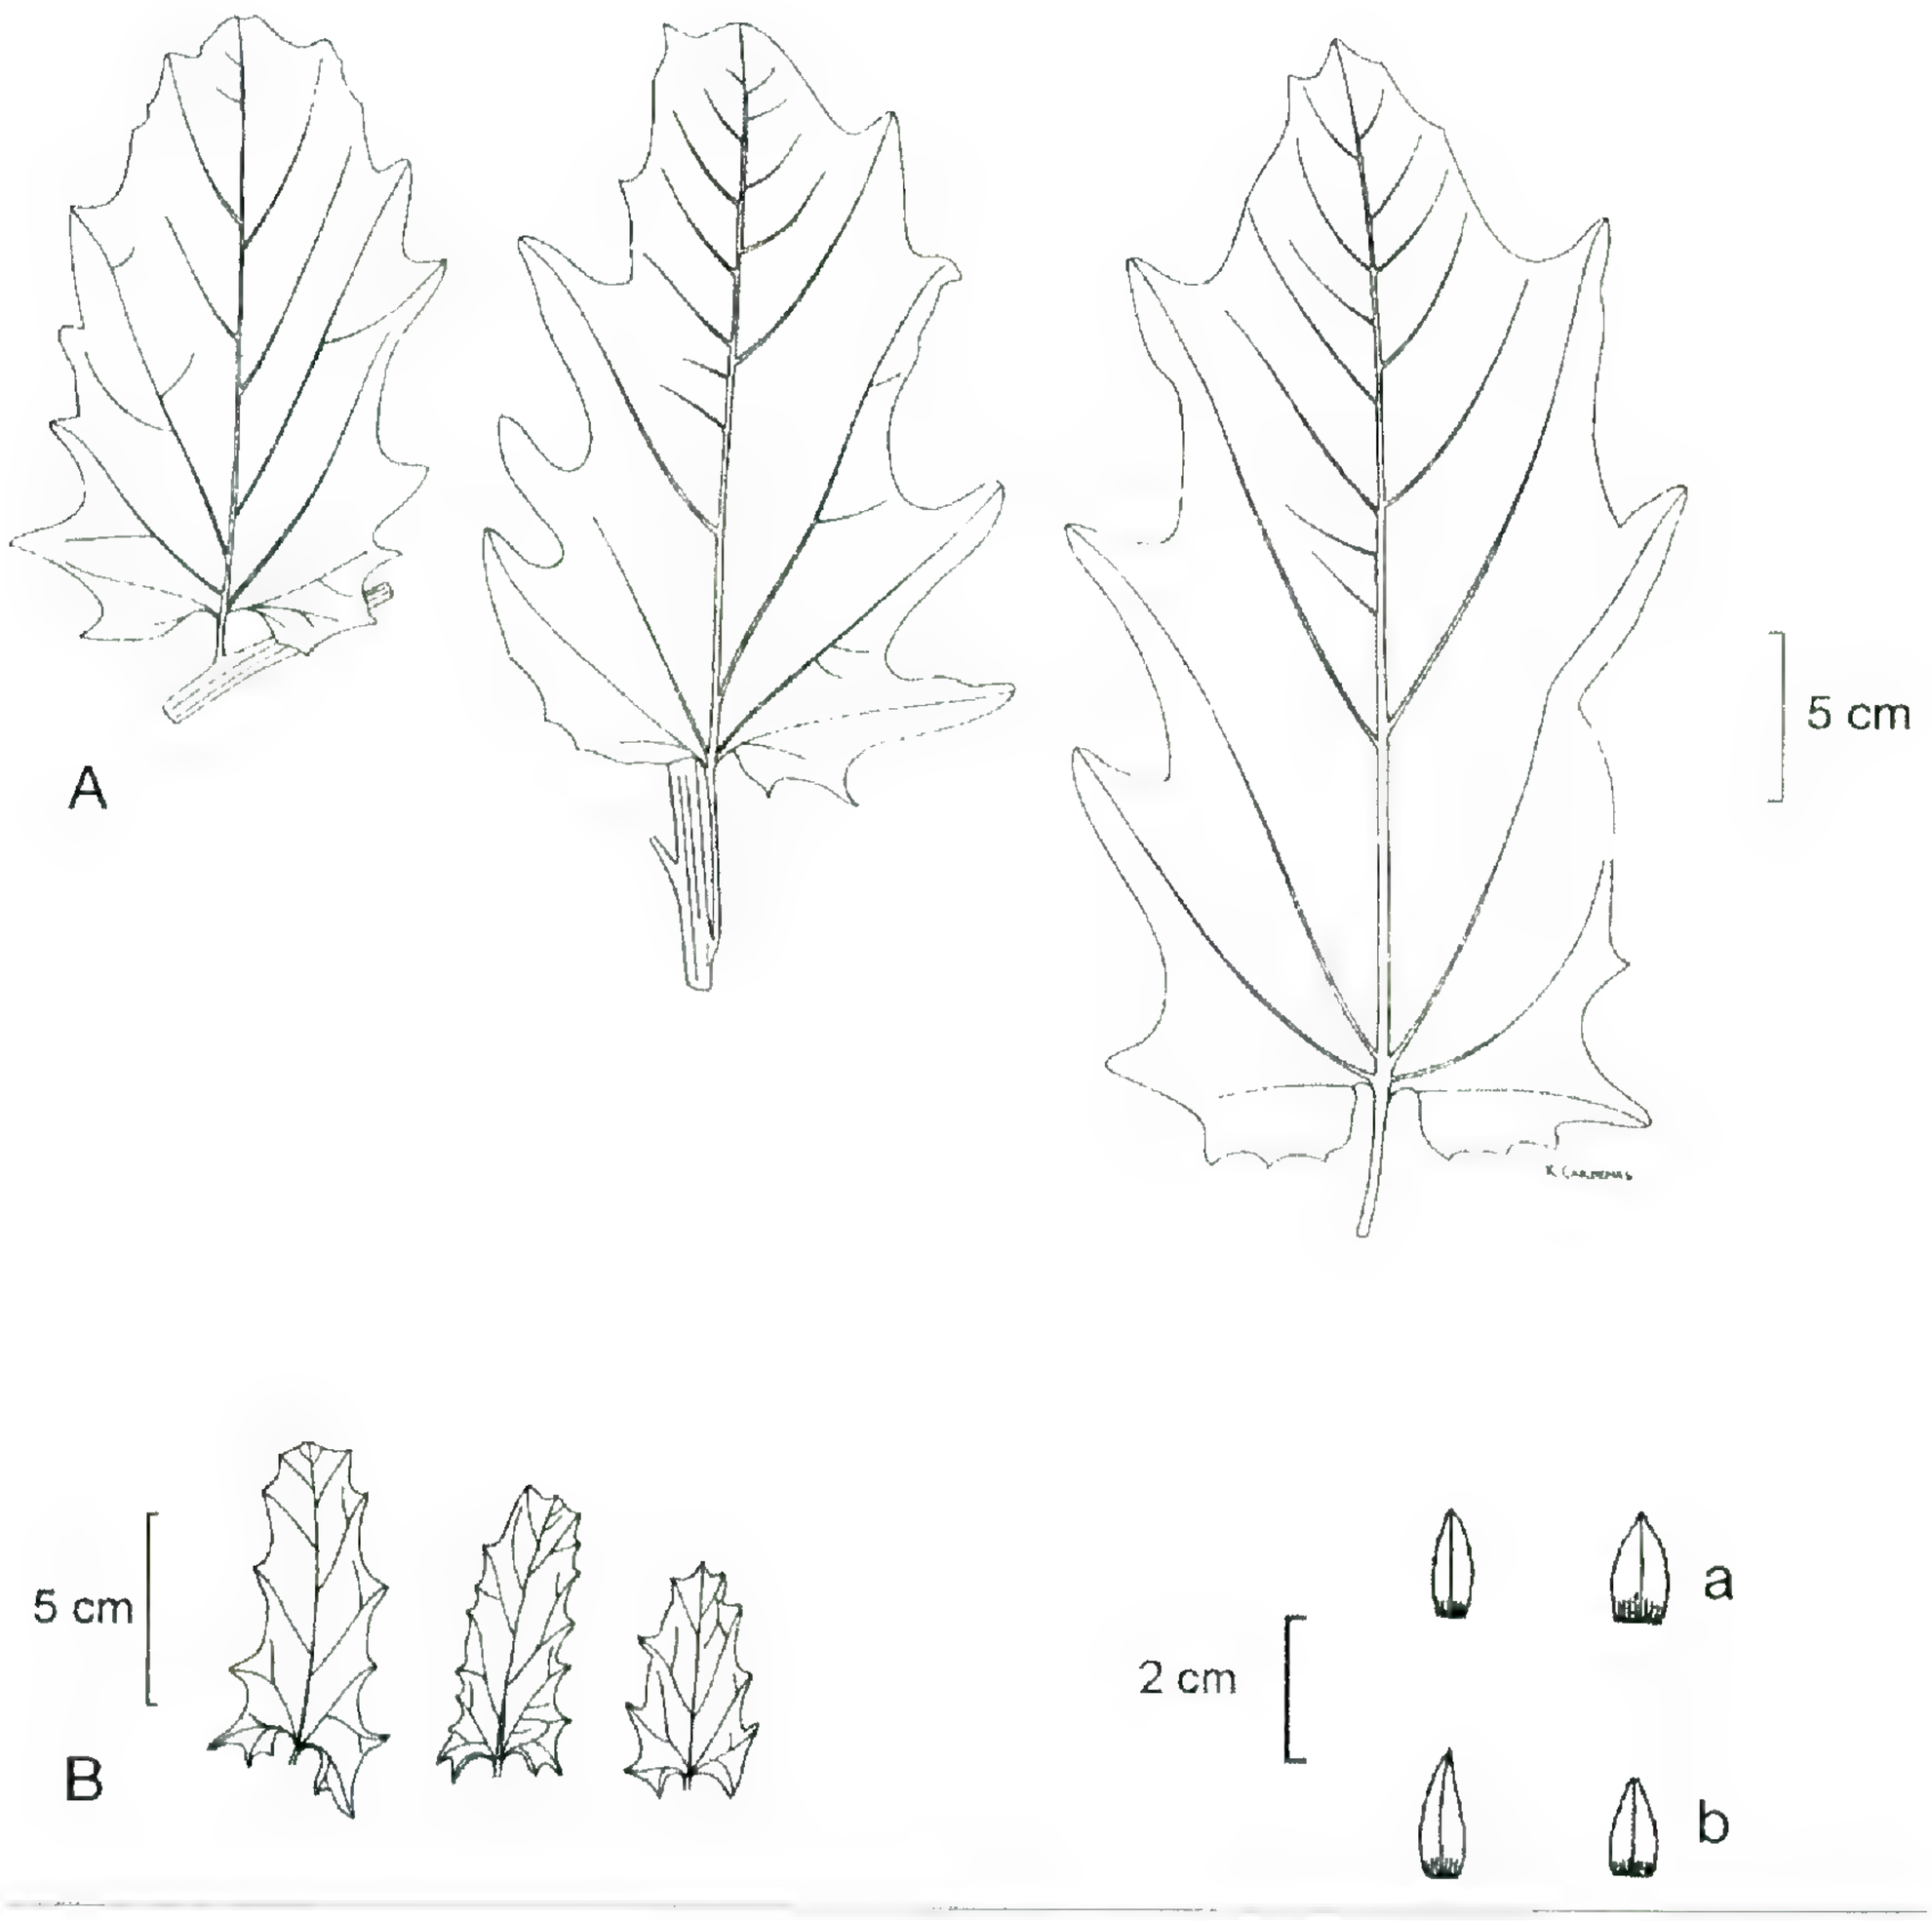

FIG. 2. Variación en tamaño de las hojas (A–B) y en la forma de los sépalos (a–b) de *Ipomoea tacambarensis* (A, a) e *Ipomoea stans* (B, b).

hasta 3 cm de grosor cerca de la base, ramificados a (30–)40 a 50 cm arriba de la base, ligeramente puberulentos; lámina foliar de contorno oblongo-ovado a anchamente elíptico, de (10–)16 a 30(–35) cm de largo, de (5–)12 a 24 cm de ancho, ápice redondeado a obtuso, base truncada a subcordada, margen profundo e irregularmente sublaciniado o dentado-lobulado, lóbulos agudos, mucronulados, venación conspicua en el envés, superficie puberulenta, a veces diminutamente pilosa en el envés, primordialmente sobre las nervaduras, pecíolo de (1.2–)2 a 4.5(–6) cm de largo, de 2 a 3(–5) mm de grueso, piloso, acanalado por el haz; inflorescencias axilares y terminales, en cimas dicasiales y monocasiales, flores (3–)5 a 15, pedúnculo primario de (6–)9 a 18(–20) cm de largo, de 2 a 3(–4) mm de grueso, glabrescente o piloso, pedúnculos secundarios de 7 a 15(–25) mm de largo, glabros, a veces pilosos, brácteas caedizas, linear-lanceoladas u oblongo-

ovadas, membranosas a escariosas, de 12 a 17 mm de largo, de hasta 6 mm de ancho, margen erósulo, o a veces irregularmente ciliado, pedicelos de (8–)12 a 30 mm de largo, glabros; sépalos escariosos, iguales o inconspicuamente subiguales, oblongo-ovados, de (13–)15 a 17 mm de largo, de 6 a 8 mm de ancho, los interiores ligeramente más anchos, glabros, rara vez los exteriores apenas pilósulos; corola infundibuliforme, de color rojo vino a azul-purpúreo, de 7 a 9 cm de largo, de 6 a 9 cm de diámetro en el limbo, el tubo más pálido que el limbo; estambres desiguales, de 2 a 4 cm de largo, filamentos blancos, pubescentes en la base, anteras de 5 a 7 mm de largo; estilo de 3.5 a 4 cm de largo, glabro, blanco, estigma globoso, algo bilobado; fruto una cápsula subglobosa a anchamente ovoide, bilocular, 4-valvada, de (8–)9 a 11 mm de largo, de (7–)8 a 9 mm de diámetro, glabra, de color pajizo a café oscuro; semillas 4, elipsoides, ± 3-anguladas, de color café, de (5–)6 a 8 mm de largo, de 4 a 6 mm de ancho, diminutamente pubescentes.

Ejemplares examinados: **MÉXICO. Michoacán. Municipio de Tacámbaro:** ± 8 km de Paso de Morelos, camino a Villa Madero, 3 Sep 2003, *E. Carranza* y *V. Steinnman* 6397 (IEB); al N de Paso de Morelos, 3 Ago 2003, *E. Carranza* y *P. Carrillo* 6390 (IEB).

Debido al hábito peculiar de esta planta, las hojas sublaciniadas o irregularmente dentado-lobuladas, fruto bilocular con semillas diminutamente pubescentes, la especie debe incluirse en *Ipomoea* serie *Tyrianthinae* (House) D. F. Austin, al lado de *I. ancisa*, *I. sescossiana* e *I. stans* (McDonald 2001).

El aspecto general de esta planta es similar al de *Ipomoea stans* Cav., principalmente en lo que respecta al porte erecto y la forma de las hojas. Sin embargo, *I. tacambarensis* tiene sépalos iguales o apenas subiguales, oblongo-ovados, los interiores un poco más anchos, hojas generalmente de 16 a 30 cm de largo y 12 a 24 cm de ancho y cimas multifloras. En contraste *I. stans* posee sépalos generalmente desiguales, los externos elípicos, los internos angostamente elípticos, hojas de 2.5 a 7 cm de largo, de 0.6 a 3 cm de ancho y flores solitarias. En el cuadro 1 se señalan con mayor detalle las diferencias entre estas especies.

Ecología.—El área donde prospera *I. tacambarensis* tiene suelos de tipo regosol y acrisol que se asientan sobre rocas de orígen ígneo, principalmente areniscas y conglomerados, entre 1500 y 1950 m de altitud. Los climas subhúmedos tanto cálidos como semicálidos predominan en el sitio tipo. Las condiciones ambientales de esta región se encuentran con diferentes grados de alteración, ocasionados básicamente por vías de comunicación, agricultura y pastoreo. Por lo menos en algunas zonas, estas plantas se ven favorecidas con dichas actividades.

Vegetación.—La vegetación donde crece esta especie varía desde la ecotonía de los bosques tropical caducifolio y de encino, en las partes con menor altitud, hasta el bosque de pino-encino en lo más alto. En la primer zona destacan especies de los géneros *Quercus*, *Bursera*, *Colubrina*, *Annona*, *Cordia* y *Ficus*. Además se encuentran plantas propias de ambientes perturbados, por ejemplo

CUADRO 1. Comparación morfológica y distribución geográfica de *Ipomoea stans* e *Ipomoea tacambarensis*.

	Ipomoea stans	***Ipomoea tacambarensis***
Hábito	Hierba erecta, hasta 1 m de alto	Hierba erecta, de más de 2 m de alto
Tallo	Hasta de 5 mm de grueso	Hasta de 30 mm de grueso
Hoja	Lámina de 2.5–7(11) cm de largo, de 0.6–3(–5) cm de ancho, subcoriácea; pecíolo de 2–4(–6) mm de largo, de 0.5–1 mm de grueso, cilíndrico	Lámina de (10–)16–30(–35) cm de largo, de (5–)12–24 cm de ancho, membranácea; pecíolo de (12–)20–45(–60) mm de largo, de 2–3(–5) mm de grueso, acanalado
Inflorescencia	Axilar; flores solitarias, rara vez en pares; pedúnculos de 0.8–5(–8.5) cm de largo, de 1–2 mm de grueso; pedicelos de 5–12 mm de largo	Terminal o axilar; cimas con (3–)5–15 flores; pedúnculos de (6–)9–18(–20) cm de largo, de 2–3(–4) mm de grueso; pedicelos de (8–)12–30 mm de largo
Sépalos	Desiguales, a veces subiguales, los externos elípticos, de 10–23 mm de largo, pubescentes, los internos angostamente elípticos	Iguales o apenas subiguales, oblongo-ovados, de (13–)15–17 mm de largo, de 6–8 mm de ancho, los interiors ligeramente más anchos, glabros, rara vez los exteriores pilósulos
Estilo	2.5–3 cm de largo	3.5–4 cm de largo
Distribución	Ampliamente distribuida en regiones semiáridas de México (Dgo., Zac., S. L. P., Gto., Qro., Hgo., Jal., Mich., D. F., Mor., Pue., Tlax., Ver., Oax.)	Restringida hasta donde se conoce, a una región semihúmeda de Michoacán, en la vertiente sur del Eje Neovolcánico hacia la Depresión del Balsas.

de los géneros *Verbesina* y *Acacia*, que manifiestan claramente la alteración de la vegetación. La zona de mayor altitud, donde también destacan elementos indicadores de disturbio, concentra como especies dominantes las que son propias de estas comunidades sobresaliendo *Pinus oocarpa* y *Quercus magnoliifolia*.

Al igual que otras especies de *Ipomoea*, a *I. tacambarensis* se le conoce con el nombre de "quiebraplatos." De acuerdo con los pobladores del lugar, tradicionalmente, los tallos y hojas son hervidos y utilizados a manera de baños, para contrarrestar los efectos de la picadura de animales venenosos (alacranes, víboras y otros); acompañados frecuentemente por la ingestión de un té preparado con el tubérculo de las mismas plantas.

El nombre de la planta alude al municipio de Tacámbaro en el estado de Michoacán, lugar donde crecen estas poblaciones.

Distribución.—Hasta ahora, sólo se conoce de la localidad tipo y en otro sitio relativamente cerca de ésta. Se sabe además, por información de los habitantes de la zona, que se encuentra en varias de las numerosas cañadas y

laderas similares, aledañas al área de colecta. Es probable que se trate de una planta endémica a esta región.

Fenología.—Florece de agosto a septiembre y los frutos maduran algunos meses después, encontrándose sus restos aún al principio de la floración del siguiente año.

AGRADECIMIENTOS

Deseo expresar mi agradecimiento a J. Rzedowski por la revisión crítica del manuscrito, en especial la diagnosis en latín, lo mismo que a A. McDonald y V. Steinmann. Igualmente agradezco a este último y a P. Carrillo por su compañía durante las exploraciones de campo, así como a R. Cárdenas por la elaboración del dibujo. Finalmente, este trabajo ha sido posible gracias al apoyo económico brindado por el Instituto de Ecología, A. C. (cuenta 902-07).

PORTULACA MATTHEWSII (PORTULACACEAE), A NEW SPECIES FROM THE "SIERRA GORDA" BIOSPHERE RESERVE, QUERÉTARO, MEXICO[1]

Gilberto Ocampo Acosta

Instituto de Ecología, A.C., Centro Regional del Bajío
Pátzcuaro, Michoacán, MÉXICO
ocampo@inecolbajio.edu.mx

ABSTRACT

Portulaca matthewsii is proposed and described as a new species. It belongs to subg. *Portulaca* sect. *Catoclasis* subsect. *Conocarpae*, and has been collected in the northern part of the "Sierra Gorda" Biosphere Reserve, in the Mexican state of Querétaro. The new taxon primarily differs from the known Mexican species of this subsection by the fibrous roots and by the stellate-tuberculate surface of the seed.

KEY WORDS: Mexico, *Portulaca*, Portulacaceae, Querétaro, "Sierra Gorda" Biosphere Reserve

RESUMEN

Se propone y describe a *Portulaca matthewsii* como especie nueva para la ciencia. Este taxon se ubica en el subgénero *Portulaca*, sección *Catoclasis*, subsección *Conocarpae*, y ha sido colectada en la porción norte de la Reserva de la Biosfera "Sierra Gorda", en el estado mexicano de Querétaro. La entidad nueva se diferencia de las especies de la subsección conocidas para México por la presencia de raíces fibrosas, así como por la superficie de la semilla que es estelulado-tuberculada.

PALABRAS CLAVE: México, *Portulaca*, Portulacaceae, Querétaro, Reserva de la Biosfera "Sierra Gorda"

During preparation of the treatment of Portulacaceae for the *Flora del Bajío y de Regiones Adyacentes*, Mexico, some specimens of the genus *Portulaca* collected in the "Sierra Gorda" Biosphere Reserve in the state of Querétaro were detected to have a campanulate capsule operculum. This feature, in addition to others, places the specimens in subsect. *Conocarpae* D. Legrand (subg. *Portulaca* sect. *Catoclasis* D. Legrand (Legrand 1962)). (Even though Legrand's approach is focused mainly in the American species of *Portulaca* and does not consider the variation presented by the genus in a global scale, his systematic arrangement has been very useful in characterizing the New World Portulacas; nevertheless, a modern revision for the whole genus is considered necessary). Beyond this placement, they could not be determined to species, so here they are proposed as:

[1]Research supported by the Instituto de Ecología, A.C. (account number 902-07), by the Consejo Nac onal de Ciencia y Tecnología (Conacyt, Mexico) and by the Comisión Nacional para el Conocimiento y Uso de la Biodiversidad (Conabio, Mexico).

Portulaca matthewsii G. Ocampo, sp. nov. (**Fig. 1**). TYPE: MEXICO. QUERÉTARO. Municipality of Landa: Puerto del Gato, 3 km al W de Acatitlán de Zaragoza, bosque de encino, ladera de cerro, 1450 m, 29 Jul 1988, *E. González 44* (HOLOTYPE: IEB; ISOTYPES: MEXU, QMEX, XAL).

Herba perennis crassiuscula; radix fibrosa; caules usque ad 15 cm longi, prostrati vel decumbentes; folia alterna, subteretia, lanceolata, oblongo-lanceolata, oblanceolata vel elliptica, 3–10 mm longa, 0.6–2.5(–3) mm lata, apice acuta vel subacuta, aliquando obtusa; sepala deltata, rubra, (3–)3.5–4.5(–5) mm longa, 2.5–4(–4.5) mm lata; petala magentea vel purpurea, obovata vel oblongo-obovata, (4–)5.5–8 mm longa, (2.5–)3–4 mm lata; stamina (13–)16–28; stylus (3–)4–5 mm longus, lobis stigmatosis 3(–4); capsula (2.5–)3–4(–4.5) mm longa, operculum campanulatum; semina reniformia, nigra vel coracina, (0.5–)0.6(–0.7) mm longa, testa stellato-tuberculata.

Fleshy perennial herb with fibrous roots; stems several from the base, usually suffrutescent in their lower portion, prostrate to decumbent, 4–15 cm long, sparsely branched above, glabrous; axilar hairs scarce, 3–5(–6) mm long; leaves alternate; petiole 1–1.5(–2) mm long; lamina lanceolate, oblong-lanceolate or oblanceolate to elliptic, 3–10 mm long, 0.6–2.5(–3) mm wide, subterete in cross section, apex acute to subacute, rarely obtuse; flowers clustered in a head in groups of 4–7, subtended by an involucre of 6–8(–10) leaves, surrounded by hairs 3–4.5(–5) mm long; sepals reddish, deltate, clasping, (3–)3.5–4.5(–5) mm long, 2.5–4(–4.5) mm wide, apex acute, margin scarious; petals magenta to purple, obovate to oblong-obovate, (4–)5.5–8 mm long, (2.5–)3–4 mm wide, apex obtuse to emarginate, usually apiculate; stamens (13–)16–28; filaments connate at the base and forming a tube 0.6–0.8 mm long, the filaments (2–)2.5–3.5 mm long; anthers 0.4–0.6(–0.7) mm long; style (3–)4–5 mm long, stigma lobes 3(–4); fruiting pedicel 0.5–0.7 mm long; capsule (2.5–)3–4(–4.5) mm long, 2–3 mm in diameter, circumscissile in the lower third; operculum campanulate; seeds (0.5–)0.6(–0.7) mm long, reniform, black to bluish-black, testa with tubercles stellate at the base.

Additional specimens examined: **MEXICO. Querétaro. Municipality of Jalpan:** 3–4 km al N de La Parada, 20 Jun 1991, *B. Servín 1146* (IEB); ± 2 km de La Tinaja, camino a El Lindero, 15 Aug 1989, *E. Carranza 1976* (IEB). **Municipality of Landa:** ± 0.5 km al SW de El Lobo, 15 Aug 2002, *G. Ocampo & E. Pérez 1202* (IEB); 1 km al SW de El Lobo, 1 Aug 1987, *J. Rzedowski 44051* (ENCB, IEB); ± 4 km al E de La Vuelta por la carretera a Xilitla, 25 Sep 2002, *S. Zamudio & V. Steinmann 12125* (IEB); along MEX 120, 5 km (by road) E of the turnoff to La Vuelta, 25 Sep 2002, *V. W. Steinmann & S. Zamudio 2832* (IEB); 12 km al SW de El Lobo, sobre la carretera a Landa, 1 Aug 1987, *J. Rzedowski 43969* (ENCB, IEB).

Portulaca matthewsii is found in the municipalities of Jalpan and Landa, Querétaro, in the northern portion of the "Sierra Gorda" Biosphere Reserve. This region is part of the Sierra Madre Oriental mountains system, and it is highly probable that the new entity also occurs in closely adjacent areas of the state of San Luis Potosí. The new species grows in rocky open places, on limestone substrate, in pine-oak forest, oak forest, oak-juniper forest and submontane scrub, as well as in grassland, from elevations of 1300 to 1600 m (4300–5200 ft). It has been collected with flowers and fruits from June to September. The local abun-

Distribution		Querétaro; possibly also San Luis Potosí	Central Mexico, (Colombia?, *P. solferina* Poelln.)	Michoacán, Estado de México, Morelos

dance of this species is reported from scarce to abundant, so it can be considered that is not in danger of extinction at present.

The new taxon belongs to subg. *Portulaca* sect. *Catoclasis* D. Legrand subsect. *Conocarpae* D. Legrand. This subsection is characterized by the size of the capsules (2.5 to 5(–6) mm long), dehiscing in its lower third portion, by its campanulate to tubular-campanulate (rarely hemispherical) operculum, as well as by its linear to oblong-elliptic leaves that are sometimes more or less compressed (D. Legrand 1962). Only two species from this subsection were previously reported to occur in Mexico: *P. mexicana* P. Wilson (Torreya 28:29. 1928) and *P. rzedowskiana* Ocampo (Sida 20:487. 2002). *Portulaca matthewsii* primarily differs from these by having fibrous roots and by the stellate-tuberculate testa of the seed. In addition, *P. mexicana* is distinguished from *P. matthewsii* by its yellow petals, and terete, linear to sublinear leaves. *Portulaca rzedowskiana* differs from the new entity by its larger dimensions of sepals, petals and capsules; and higher number of anthers and stigma lobes (Table 1).

Etymology.—The new species is named in honor of James F. Matthews, whose research on *Portulaca* represents a very important contribution to the knowledge of the genus in North America.

ACKNOWLEDGMENTS

I am grateful to Victor W. Steinmann, James Henrickson and John McNeill for helpful comments and corrections to the manuscript; and to Rogelio Cárdenas for the illustration of the new species.

BOOK REVIEW

ELIZABETH A. (BERNDT) GEORGE. Watercolour paintings and illustrations by MARGARET PIERONI. 2002. **Verticordia: The Turner of Hearts.** (ISBN 1 876268 46 8, hbk.). University of Australia Press, Crawley, Western Australia 6009, www.uwapress.uwa.edu:au. (Orders: International Specialized Book Services, 5824 NE Hassalo St., Portland, OR 97213-3644, U.S.A. 503-280-8832 fax; www.isbs.com; info@isbs.com). $84.95, 422 pp., 28 color photos, 39 figs., 44 maps, 149 color plates, 6 tables, glossary, 8 1/2" × 11 1/2".

This magnum opus is a product of ten years of collecting, mounting, and photographing 1400 specimens of *Verticordia* (Myrtaceae) by the author and more than 250 volunteer helpers. Furthermore, the artist, Margaret Pieroni, worked over a period of eighteen years to paint the 147 species, subspecies, and varieties pictured in the book. She wanted to paint each plant in full flower from the actual specimen and not only had to depend on chance to achieve that, but over the years the number of known species kept increasing. The result of this collaboration is a very comprehensive study of a genus unique to Western Australia and the Northern Territories. It is a splendid introduction for anyone who wants to become familiar with this less well known genus and a valuable resource for the specialist.

The enormous amount of material about *Verticordia* has been well-organized by the author. Her introduction discusses every aspect of the genus: from its ancient origins to its cultivation today, from chromosome studies to its use in art and craft.

The following section contains tables of species arranged by chronological order of naming, by chromosome number, by flowering characteristics, and by habit. There is a good glossary, and a key to infrageneric taxa and species. A line drawing illustrates each subgenus and section.

The main part of the book is devoted to the illustrations and treatments of the species. Each of the 102 color plates is faced by a page of text and a map showing where the species may be found. The watercolors are in the genre of botanical painting where the aim is to convey information, and these paintings show close scrutiny of the specimen by the artist. A line drawing of the reproductive system of the plant is included on each plate. This is somewhat unfortunate especially when the painting is on a colored background. The decision to show the flowering twig precluded the possibility of portraying the habit of this shrubby plant. The spectacular masses of color can be seen in the photographs.

The author's aim is to share information about *Verticordia*. It is a worthwhile project as the genus may not be well-represented in herbaria outside of Australia. The BRIT Herbarium of about 1,000,000 specimens has only ten examples of this interesting genus.—*Ruth Ginsburg, Botanical Research Institute of Texas, Fort Worth, TX, 76102-4060, U.S.A.*

ABSTRACT

A new species, **Chaptalia hidalgoensis** L. Cabrera & Nesom, is described and illustrated. It is known only from the type collection made in Mun. Zimapan, Hidalgo. The occurrence of *Chaptalia mexicana* Burkart is documented here, with description and illustration, apparently for the first time since the type was collected by Ehrenberg in 1840. The recent collection was made in Mun. Pinal de Amoles, Querétaro. Both of these Mexican species appear to be members of sect. *Chaptalia*.

RESUMEN

Una nueva especie, **Chaptalia hidalgoensis** L. Cabrera & Nesom, se describe e ilustra; ésta se le conoce únicamente de la colección tipo del Mun. Zimapan, Hidalgo. También documentamos la existencia de *Chaptalia mexicana* Burkart, proporcionando una descripción completa e ilustración; aparentemente esta especie no se había vuelto a colectar desde la colecta tipo de Ehrenberg en 1840. Esta colección reciente es del Mun. Pinal de Amoles, Querétaro. Ambas especies mexicanas parecen ser miembros de la sección *Chaptalia*.

Research by the first author toward a treatment of Mutisieae of the Bajío region of México has brought to light two interesting discoveries in *Chaptalia* Vent. A new species is described, and the first known collection of *C. mexicana* Burkart since its initial discovery in 1840 is documented.

Chaptalia hidalgoensis L. Cabrera & Nesom, sp. nov. (**Fig. 1**). TYPE: MEXICO. HIDALGO: Mun. Zimapan. Verdosas, bosque de pino, encino y *Juniperus*, 1750 m, 20 Nov 1991, *V.M. Huerta 1352* (HOLOTYPE: IEB!).

Chaptaliae lyratifoliae et alio sect. *Chaptaliae* similis flosculis centralibus fungenter staminatis—differt ab omnibus coniunctione rhizomatum, scaporum bracteatorum, foliorum coriaceorum lyratorum, flosculorum pistillatorum interiorum numerosorum, et acheniorum non rostratorum; differt a *C. lyratifoliae* scapis bracteatis, phyllariis marginibus glandulosis, flosculis pistillatis exterioribus paucioribus ac flosculis pistillatis interioribus multo paucioribus, et flosculis bisexualibus corollis brevioribus.

Plants perennial, fibrous-rooted, rhizomatous. **Leaves** coriaceous, 3–5 cm long, blades 1.5–3.6 cm long, 1.1–2.1 cm wide, elliptic-oblong to ovate, lyrate, with an ovate to ovate-cordate terminal portion and 1(–2) pairs of basal lobes, margins

[1]Current address: Leticia Cabrera R., Biological Sciences Department, Northwest Missouri State University, 800 University Drive, Maryville, MO 64468, U.S.A.

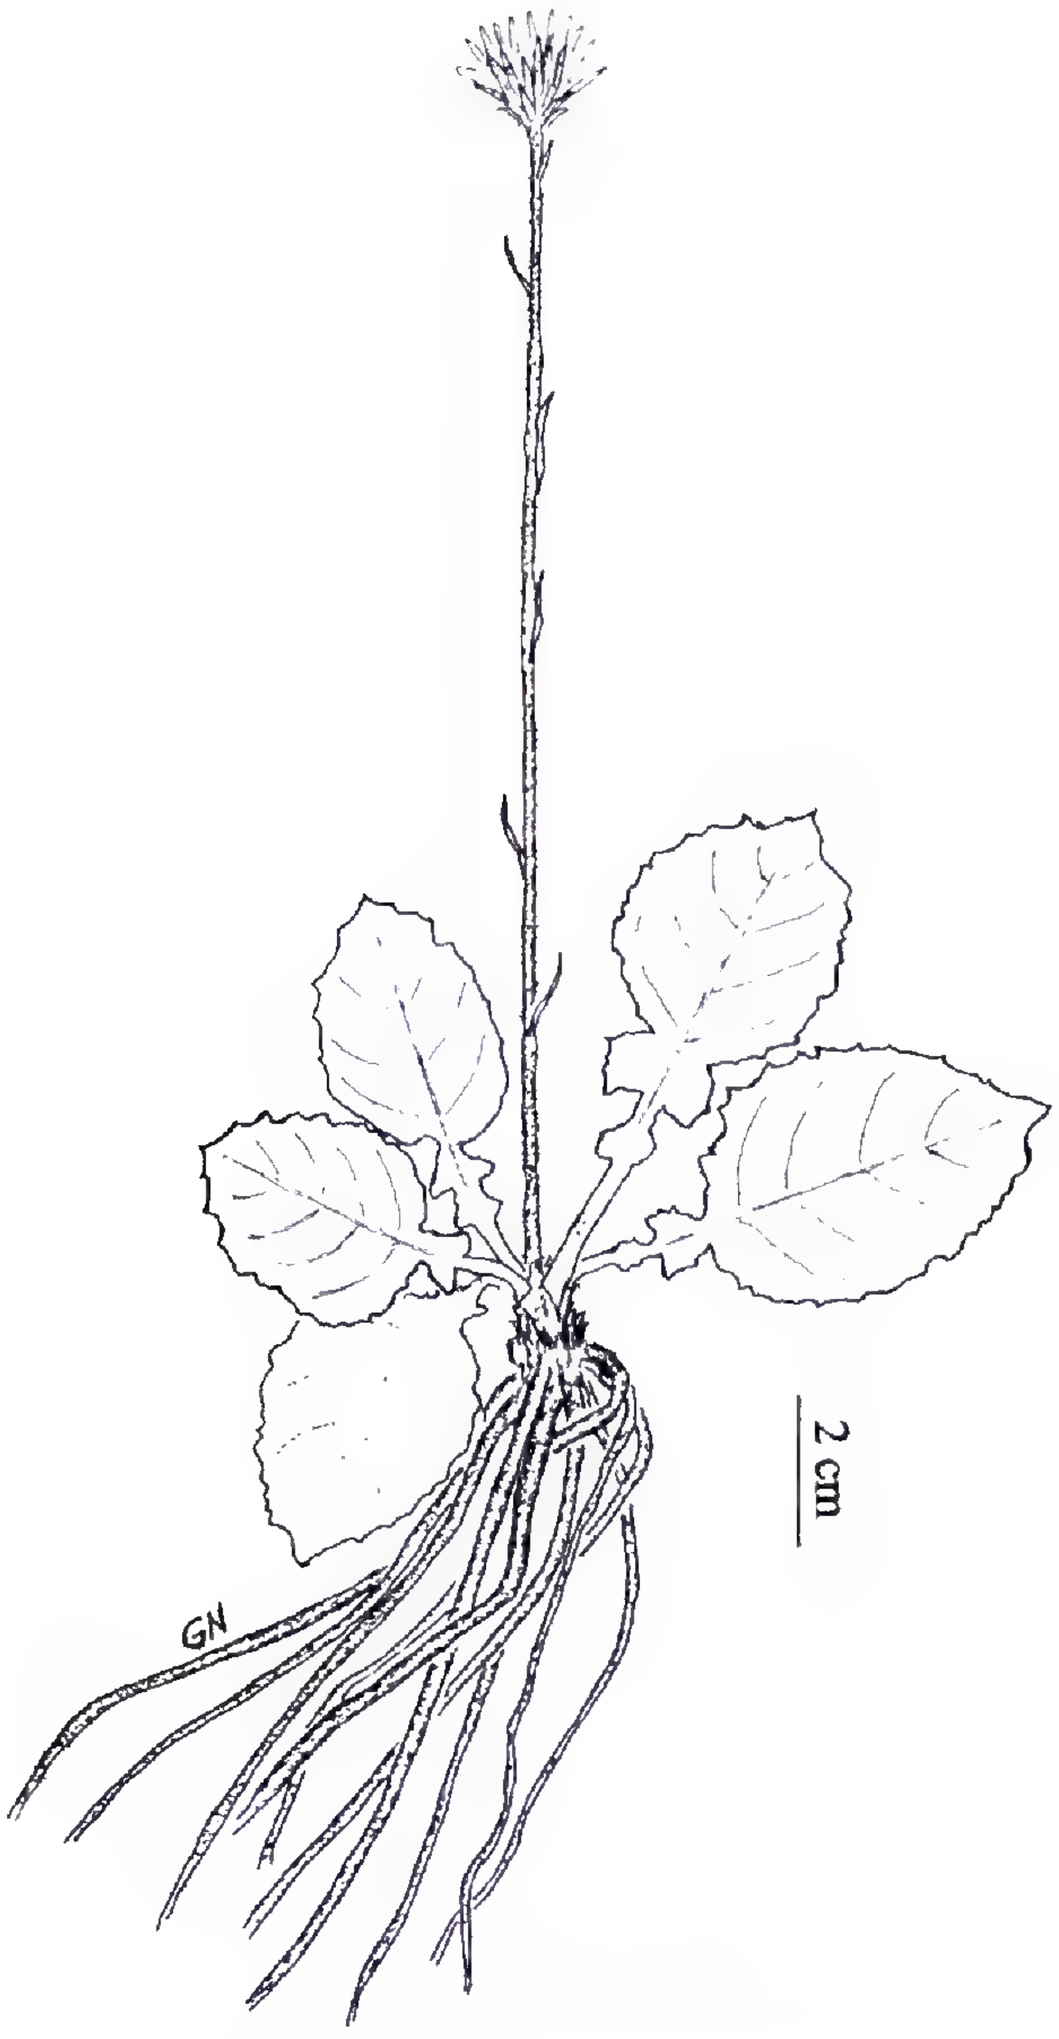

Fig. 1. Habit of *Chaptalia hidalgoensis*, from the type.

crenate to denticulate, revolute, apex acute to obtuse and mucronate, the base cordate, lower surface white-gray tomentose, upper surface villous-arachnoid, glabrescent. **Scapes** 1–3 per plant, 8–12 cm tall, villous to almost glabrous, tomentulose close to the head, 6–9-bracteate, bracts linear-lanceolate, 3–5.2 mm long, also with 3 bract-like phyllaries close to or subtending the involucre (i.e., bracts transitional to phyllaries). **Heads** solitary, 1.1–1.7 cm tall, 1.4–1.8 cm wide; involucres turbinate, 0.8–0.9 cm tall, phyllaries 3-seriate, green, herbaceous, all acute, scarious at the margins, with the distal area usually dark-red, the dorsal surface somewhat arachnoid, soon glabrous, the outermost linear-lanceolate, ca. 2.8 mm long, 0.5–0.7 mm wide, margins sparsely glandular, the central lanceolate, 4–5.2 mm long, 0.8–1 mm wide, margins sparsely glandular, the innermost ca. 8 mm long, ca. 1 mm wide, margins glabrous. **Florets** trimorphic—*outer*

pistillate and ligulate, *middle* pistillate with reduced ligules, *inner* bisexual and tubular-bilabiate: **outer florets** 15–21 in 1 series, ligules white-cream in color, sometimes somewhat purple with age, with an abaxial purplish midstripe at maturity, 10 mm long, ca. 1 mm wide, the tube 2.8 mm long, the inner lips 1–3, filamentous, 1–1.2 mm long, the style 5.2 mm long, including the branches 0.2–0.3 mm long; **middle florets** ca. 7, ligules ca. 6 mm long, ca. 0.4 mm wide, the tube almost as long as the ligule, inner lip absent; style 6 mm long including the ca. 0.5 mm long branches; **inner florets** ca. 22, corollas bilabiate, creamy in color, 7 mm long, including the 5 mm long tube and the recurved lobes 2–3 mm long; stamens 4.5 mm long, appendage 1.5 mm long, tails ca. 1.2 mm long, thecae ca. 1.8 mm long. **Achenes**: (outer pistillate florets) immature but apparently fertile, ca. 2 mm long, papillose over whole surface, cylindric; pappus biseriate, ca. 5 mm long; (inner pistillate florets) fertile, ca. 2.5 mm long, fusiform, apparently not beaked, papillate; pappus uniseriate, 5–5.5 mm long; (bisexual florets) sterile, ca. 2 mm long, cylindric, with few hirsute hairs; pappus biseriate, 6.2 mm long. Known only from the type collection, where it was reported as scarce.

Chaptalia hidalgoensis (as well as *C. mexicana*, below) appears to be a member of sect. *Chaptalia*, as outlined by Nesom (1995)—recognized by the production of functionally staminate (pseudo-bisexual) central florets, ligules of the outer pistillate florets with a purplish, abaxial midstripe at maturity, and heads nodding in bud. Previously, only one of the six species of sect. *Chaptalia* was known to produce consistently bracteate scapes—both of the species discussed in the present manuscript have bracteate scapes. The behaviour of the heads in the two species treated here in detail is inferred from their putative relatives.

Within sect. *Chaptalia*, *C. hidalgoensis* mostly closely resembles *C. lyratifolia* Burkart in its coriaceous and lyrate leaves. One of the plants of the Huerta collection shows production of short rhizomes (the other plant collected without any below-ground parts) and because of the similarities of *Chaptalia hidalgoensis* to *C. lyratifolia*, which characteristically is colonial through production of creeping or stoloniform rhizomes, it seems probable that *C. hidalgoensis* also has a colonial habit. A summary of distinctive contrasts of the new species with *C. lyratifolia* is given in the key below (following comments on *C. mexicana*). The latter species is distributed from central Nuevo León and adjacent Coahuila and Tamaulipas into central San Luis Potosí.

Rediscovery of *Chaptalia mexicana*

Chaptalia mexicana Burkart was described and illustrated (Burkart 1944) from a single collection, cited below. A more recent collection from Querétaro is the second known and documents its continued existence, although the species, which was inadvertently omitted in Nesom's review of the North American and Central American species (1995), apparently is rare elsewhere.

Chaptalia mexicana Burkart, Darwiniana 6:543. 1944 (**Fig. 2**). TYPE: MEXICO. [No other locality data], 1840, *Ehrenberg 1042* (HOLOTYPE: B, fide Burkart 1944).

Recent collection: **MEXICO. Querétaro:** Mun. Pinal de Amoles, más o menos 2 km al N de Puerto de Tejamanil, bosque de encino, ladera de cerro, cañada, 2400 m, 27 Mar 1989, *E. Carranza 1571* (IEB). The sheet includes three plants.

Plants perennial, fibrous-rooted, producing rhizomes at least to 1.4 cm long. **Leaves** 3.5–9.2 cm long, dissected into 5–7 pairs of somewhat retrorse lobules, these increasing in size distally, the terminal lobe 1.6–3 cm long, 1.1–2.1 cm wide, ovate to ovate lanceolate, with the margins retrorse-crenate, the lower surface gray-white tomentose, the upper surface dark-green with red-tinges, lightly villous to glabrous with age, the midvein very prominent, villous-tomentose, dark red, becoming white-tomentose distally; petioles 0.8–1.5 cm long, winged, white-villous. **Scapes** 1–2 per plant, 4–10.5 cm tall, white-tomentose, (2–)4–6[8–10]-bracteate, bracts linear-lanceolate to trullate, 4–5.5 mm long, 0.5–0.8 mm wide. **Heads** solitary, 1.4–2 cm tall, 1.1–1.8 cm wide; involucres 0.9–1.3 cm tall, turbinate-campanulate, phyllaries 3-seriate, acuminate, the outermost red-dark, somewhat herbaceous, linear-lanceolate, 4–5.5 mm long, 0.5–0.8 mm wide, scarious at the margins, arachnoid on the dorsal surface, the central red-dark to green, somewhat scarious, lanceolate, 10–11 mm long, ca. 1 mm wide, scarious on the margins, somewhat villous on the dorsal surface, the innermost more or less scarious to somewhat greenish, lanceolate, 12–13 mm long, ca. 1 mm wide, glabrous dorsally. **Florets** trimorphic—*outer* pistillate and ligulate, *middle* pistillate with reduced ligules, *inner* bisexual and tubular-bilabiate: **outer florets** 15–17 in 1 series, ligules white-cream, with an abaxial purple midstripe when mature, [7]12–14 mm long, 1.1–1.8 mm wide, the tube 3–3.5 mm long tube, the inner 2 lips ca. [1]1.5–2.1 mm long, filamentous; style ca. 5.8–8 mm long, including the [0.6]0.2 mm long branches; **middle florets** 7 mm long, 0.7 mm wide, the tube 2.5–3 mm long, inner lip ca. 0.5 mm long; style 8 mm long including the ca. 0.2 mm long branches; pappus 5 mm long; **inner florets** 17–20, 8.5 mm long, the tube ca. 4.5 mm long, the semi-erect to recurved lobes ca. 4 mm long; stamens ca. 6 mm long, the filaments 2 mm long, the tails ca. 1.2 mm long, the appendage ca. 1.5 mm long, thecae ca. 2.5 mm long, fertile. **Achenes**: (outer pistillate florets) fertile, ca. 3–4 mm long, fusiform, papillose; pappus biseriate, 4–7 mm long; (inner pistillate florets) fertile, 3.5 mm long, fusiform, apparently not beaked, sparsely papillose, pappus 5 mm long; (bisexual florets) sterile, ca. 3 mm long, narrowly cylindric, glabrous; pappus uniseriate, 8 mm long. Square brackets [ ] enclose data from Burkart description.

The scape of the Ehrenberg type of *Chaptalia mexicana* (as illustrated by Burkart) appears to have 8–10 bracts, vs. (2–)4–6 in the recent Carranza collection, and several other measurements in Burkart's description vary from the recent collection, but the combination of bracteate scapes and the highly dis-

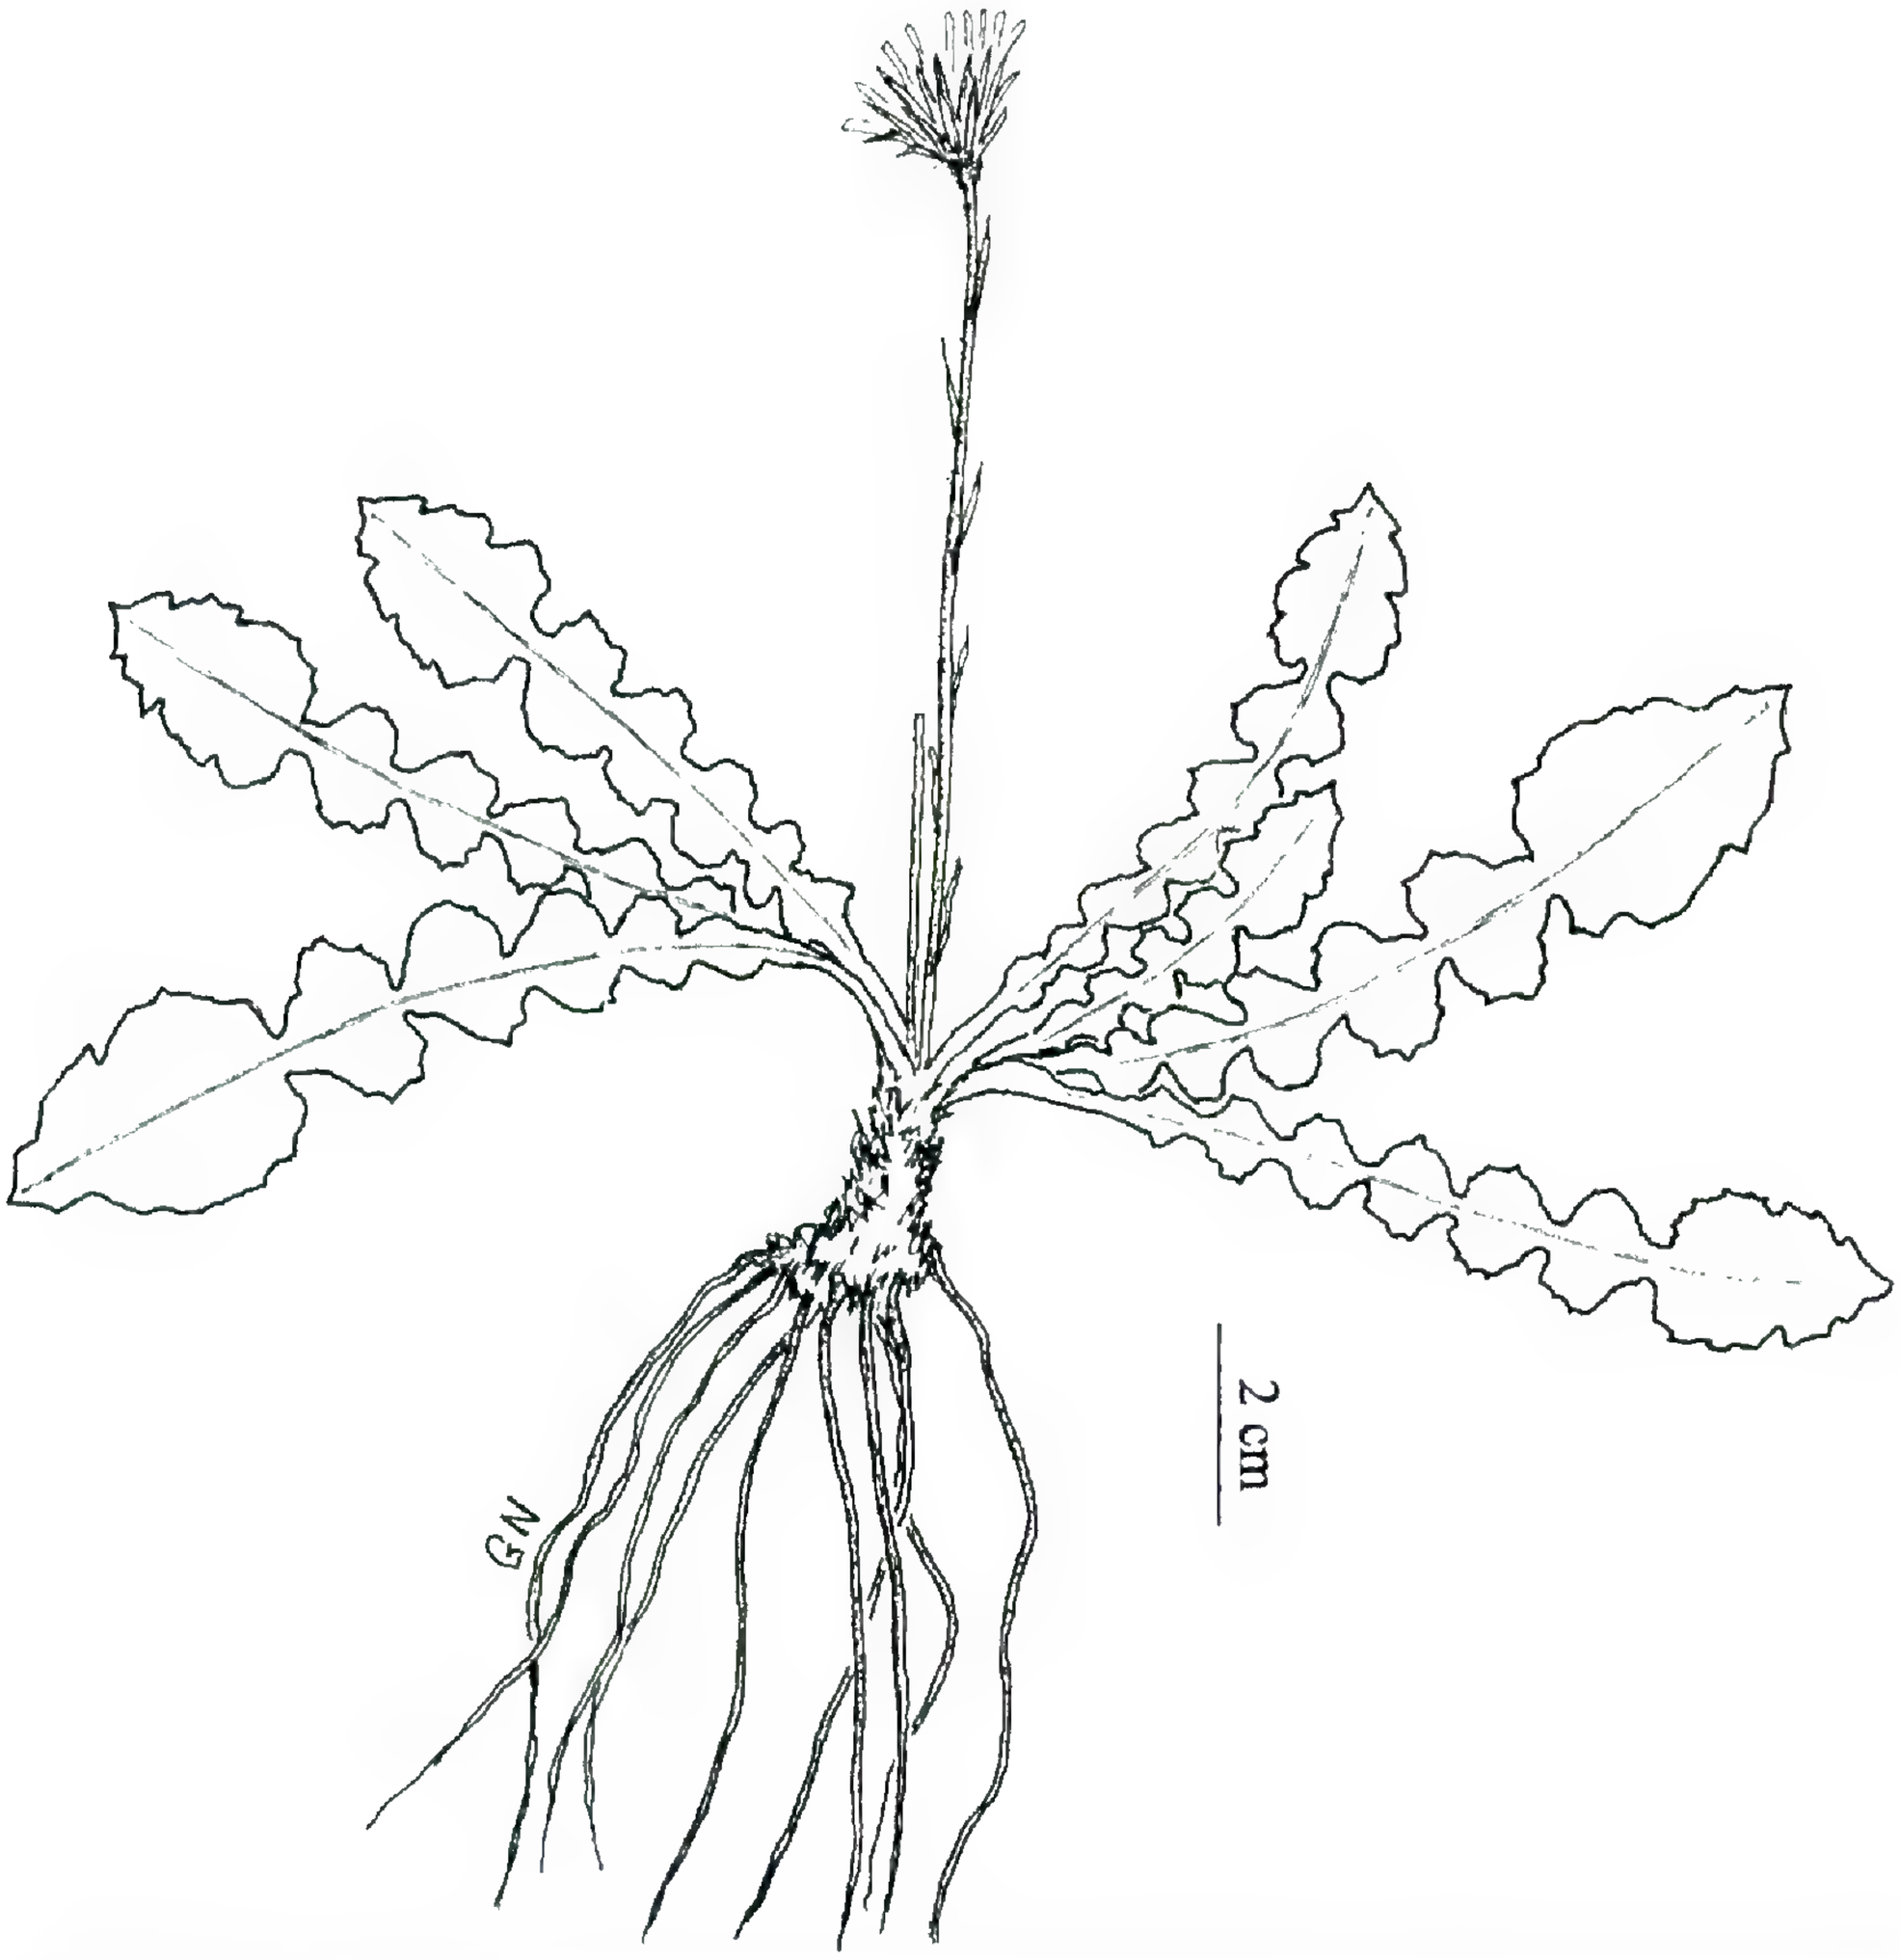

FIG. 2. Habit of *Chaptalia mexicana*, from *Carranza 1571*.

sected leaves is so remarkable that it is difficult to conclude that these are not the same species.

To arrive at an identification of *Chaptalia mexicana* using Burkart's key (1944, p. 524), which places the species in sect. *Lieberkuhna*, one must follow the choice "Flores centrales hermafroditas" (vs. "Flores centrales del capítulo masculinas, con ovario atrofiado."). His protologue for the species described "flores centrales hermafroditas" (p. 544), but he explicitly noted further down in the description that he did *not* see the achenes (probably meaning mature achenes, since his illustration included essentially similar ovaries at the base of each of the three kinds of corollas). It seems clear that Burkart would have placed this species in his sect. *Euchaptalia* if he had observed central florets

with sterile achenes. Our observation is that ovaries of the central (pseudo-bisexual) florets of *Carranza 1571* are glabrous and remain narrowly cylindric, while those of the pistillate florets are papillose and swell with the production of embryos.

Ehrenberg's type collection apparently did not include rhizomes, and the rhizomes on the Carranza collection are short, but because of the similarities of *C. mexicana* to *C. lyratifolia* and *C. estribensis* (leaves coriaceous and lyrate to cordate; style branches U-shaped, see comments below), it seems likely that the former also is colonial through production of creeping or stoloniform rhizomes.

KEY TO THE SPECIES OF SECT. *CHAPTALIA*

1. Leaves basally attenuate, not lyratiform; plants without rhizomes, occurring individually.
   2. Scapes bracteate; pistillate florets in 1 series, prominently ligulate; fertile achenes with a short, slightly constricted neck. _____ **Chaptalia pringlei** Greene
   2. Scapes ebracteate; pistillate florets in 2 series, those of the outer series ligulate, those of the inner series with ligules absent or greatly reduced; fertile achenes with a nearly filiform beak.
      3. Leaves oblanceolate-spatulate, with a narrowly attenuate petiolar region; fertile achenes 6–9 mm long, including the slender neck 1/2–1/2 as long as the achene, sparsely papillate over the whole surface. _____ **Chaptalia madrensis** Nesom
      3. Leaves elliptic to elliptic-obovate, without a petiolar region; fertile achenes 3.5–5.2 mm long, including the slender neck 1/4–1/5 as long as the achene, glabrous except for the sparsely papillate neck region. _____ **Chaptalia tomentosa** Vent.
1. Leaves basally cordate and/or distinctly lyratiform; plants rhizomatous and colonial.
   4. Leaf blades thin-herbaceous, sometimes reddish. _____ **Chaptalia hintonii** Bullock
   4. Leaf blades thick-coriaceous, not reddish.
      5. Leaf blades cordate, without lyrate extensions, with orange-tawny vestiture on the abaxial surface. _____ **Chaptalia estribensis** Nesom
      5. Leaf blades cordate to truncate at base, distinctly lyrate, with white vestiture on the abaxial surface.
         6. Leaves dissected into 5–7 pairs of somewhat retrorse, roughly equal-sized lobules; scapes bracteate. _____ **Chaptalia mexicana** Burkart
         6. Leaves lyratiform, usually with one terminal primary lobe and 0–2(–4) smaller basal lobules; scapes bracteate or ebracteate.
            7. Scapes bracteate; phyllary margins sparsely glandular; outer pistillate florets 15–21, inner lip 1–1.2 mm long; middle florets (pistillate) ca. 7, fewer than outer; corollas of bisexual florets 7 mm long. _____ **Chaptalia hidalgoensis** Cabrera & Nesom
            7. Scapes ebracteate; phyllary margins eglandular; outer pistillate florets 24–38, inner lip absent or less than 0.5 mm long; middle florets (pistillate) often more than 90, usually 3× more numerous than outer; corollas of bisexual florets 9–12 mm long. _____ **Chaptalia lyratifolia** Burkart

Generic placement

Katinas (1998) transferred *Chaptalia hintonii* to the genus *Gerbera* Gmel., which otherwise (except for one South American species) has been recognized

only from Africa and Asia. Her rationale for the transfer emphasized the production of staminodes on the outer pistillate florets of *C. hintonii*, a feature characteristic of *Gerbera* but usually not of *Chaptalia*, and the "U-shaped" style branches of *C. hintonii*. We acknowledge that generic limits among taxa of the *Gerbera* complex are somewhat ambiguously drawn and may yet require taxonomic adjustments, but it does seem clear that *C. hintonii* is a member of the group of five species within sect. *Chaptalia* (as recognized here) characterized by production of stolons and cordate to lyratiform leaves (*C. estribensis*, *C. hidalgoensis*, *C. hintonii*, *C. lyratifolia*, and *C. mexicana*). All species of this group also produce the U-shaped style branches. Style branches are more slender and "V-shaped" in the three species of sect. *Chaptalia* with basally attenuate leaves and without stolons (*C. madrensis*, *C. pringlei*, and the type of the genus, *C. tomentosa*)—the style branch morphology is more like that of species of sect. *Leria* (DC.) Burkart, which includes *C. nutans* (L.) Polak., *C. texana* Greene, and others. The similarities of *C. tomentosa* and its two closest relatives to the five others here placed in sect. *Chaptalia*, and the apparent geographic integrity of the whole group, are taken here as evidence of close evolutionary relationship (Nesom 1995). A more detailed discussion of this problem is presented in a pair of papers by Katinas and Nesom (submitted).

ACKNOWLEDGMENTS

Loans of specimens to the first author from F, GH, IEB, MEXU, MICH, and USCH are greatly appreciated. We are grateful for helpful reviews from the editor and Beryl B. Simpson.

BOOK REVIEW

JEREMY D. GARRETT. CORAL MCCALLISTER (Illustrator). 2003. **Landscaping for Wildlife: A Guide to the Southern Great Plains.** (ISBN: 0806134895, pbk.). University of Oklahoma Press, 4100 28th Ave., Norman, OK 73069-8218, U.S.A. (Orders: www.oupress.com, 800-627-7377, 800-735-0476 [orders only], 405-364-5798 fax). $28.00, 209 pp., b/w and color illustrations, 8 1/2" × 11".

From *Landscaping for Wildlife.*—"People want to attract wildlife to their yards for a variety of reasons, but probably foremost among these is that birds and other animals bring us pleasure. The exuberant songs of cardinals and mockingbirds, the playful antics of young squirrels at feeders, and the sight of colorful butterflies dancing above wildflower patches provide us with both daily and lasting joy."

Through careful landscaping, you can make your property a year-round waystation for a wide variety of animal species, from birds, butterflies, and squirrels to bats, turtles, and opossums. Garrett explains how specific plants draw animals to your property by providing food and shelter sources.

To assist readers in designing their own "wildscape," detailed diagrams and plant listings accompany photographs of several Oklahoma Department of Wildlife Conservation-certified wildscaped properties. The detailed diagrams will help you inventory and wildscape your own property. A woodworking chapter is complete with patterns of nesting and feeding stations designed for individual wildlife species. Each section includes tables that list the common name and the scientific name of the plant or wildlife species. The tables discuss how the plants are used or what animal uses them and the relationship between flora and fauna is defined.

The detailed diagrams are especially useful in visualizing what a particular wildscaped plot will look like. Each includes a color photograph, a bird's-eye or plan view and an interpretive sketch on which the plants are identified. The bird's-eye view could be used as a guide for planting. The eleven case studies cover six kinds of settings: sunny, shady, and moist wildscapes, wildflower meadows, and butterfly and rock gardens. All of the case studies illustrate multi-layering and provision of cover.

Water sources rate their own chapter and cover several types. Three types of ponds, a re-circulating stream, and a side yard marsh are illustrated though the use of case studies. Common aquatic and wetland plants are discussed, as well as wetland-related wildlife species.

The appendices provide a design checklist and a monthly activities calendar. Sources for seeds and plants are listed, and there is a bibliography of field guides and references. Internet sites and related organizations and agencies are listed.

Landscaping for Wildlife provides beginners and experts alike with specific, detailed; yet easy-to-follow instructions for meeting water needs, feeding preferences, and nesting requirements of the wildlife found in the southern Great Plains. Although written specifically for the southern Great Plains the concept is one that could be used anywhere with appropriate substitutions for locality. Written by Jeremy D. Garrett in association with the Oklahoma Department of Wildlife Conservation and complemented by Coral McCallister's elegant and charming illustrations of wildlife as well as of various habitats and wildscapes.

The Oklahoma Department of Wildlife Conservation manages Oklahoma's wildlife resources and habitat to provide scientific, educational, aesthetic, economic, and recreational benefits for present and future generations of hunters, anglers, and others who appreciate wildlife. Jeremy D. Garrett is president of NaTour Communications, a nature-consulting firm. Coral McCallister is a biological illustrator for the Department of Zoology at the University of Oklahoma.—*Gary Jennings, Botanical Research Institute of Texas, Fort Worth, TX, 76102-4060, U.S.A.*

TAXONOMY OF THE POLEMONIACEAE: THE SUBFAMILIES AND TRIBES

Verne Grant

Section of Integrative Biology and
Plant Resources Center
University of Texas at Austin
Austin, TX 78712, U.S.A.

ABSTRACT

This paper presents a revised formal classification of the subfamilies and tribes of the Polemoniaceae based on a synthesis of new and old characters and on a traditional taxonomic approach. The genera are grouped into nine tribes and three subfamilies (Cobaeoideae, Polemonioideae, Acanthogilioideae). The five tropical and subtropical genera, which are basal in the family, fall into two primary groups: subfam. Cobaeoideae, containing *Cantua*, *Cobaea*, *Bonplandia*, and *Loeselia*; and subfam. Acanthogilioideae, containing *Acanthogilia*. The temperate herbaceous genera, which are derived, also fall into two primary groups. The subfam. Polemonioideae, related to and evidently derived from the Cobaeoideae, contains *Polemonium*, *Collomia*, *Navarretia*, *Phlox*, *Linanthus*, etc. The second main group of temperate herbaceous genera is the tribe Gilieae, which is related to the tribe Acanthogilieae and included in the same subfamily Acanthogilioideae with it. The Gilieae contains the genera *Gilia*, *Eriastrum*, *Ipomopsis*, etc. This system differs in numerous respects from the recent system of Porter and Johnson (Aliso, vol. 19(1), 2000), based on a molecular cladistic approach. Different goals and methods produce different results. It is suggested that other plant groups, which have been revised in recent times according to molecular cladistic evidence and criteria, should also be revised by taxonomic methods. Updated taxonomic classifications are needed for the useful features that they alone provide.

RESUMEN

En este trabajo se presenta una clasificación formal revisada de las subfamilias y tribus de las Polemoniaceae basada en una síntesis de caracteres nuevos y viejos mediante un método taxonómico clásico. Los géneros se agrupan en nueve tribus y tres subfamilias (Cobaeoideae, Polemonioideae, Acanthogilioideae). Los cinco géneros tropicales y subtropicales, que son basales en la familia, quedan en dos grupos primarios: subfam. Cobaeoideae, con *Cantua*, *Cobaea*, *Bonplandia*, y *Loeselia*; y subfam. Acanthogilioideae, con *Acanthogilia*. Los géneros herbáceos templados, que son derivados, también están en dos grupos primarios. La subfam. Polemonioideae, relacionada y evidentemente derivada de Cobaeoideae, contiene a *Polemonium*, *Collomia*, *Navarretia*, *Phlox*, *Linanthus*, etc. El segundo grupo principal de géneros herbáceos templados es la tribu Gilieae, que se relaciona con la tribu Acanthogilieae y está incluida también en la misma subfamilia Acanthogilioideae. Gilieae contiene los géneros *Gilia*, *Eriastrum*, *Ipomopsis*, etc. Este sistema difiere en numerosos aspectos del sistema reciente de Porter y Johnson (Aliso, vol. 19(1), 2000), basado en un método cladístico molecular. Diferentes objetivos y métodos producen resultados diferentes. Se sugiere que otros grupos de plantas, que han sido revisados recientemente con criterios y métodos cladistas moleculares deberían revisarse también por métodos taxonómicos. Las clasificaciones taxonómicas actualizadas se necesitan por las características que sólo ellas pueden ofrecer.

SIDA 20(4): 1371–1385. 2003

INTRODUCTION

Research on systematics of the Polemoniaceae is going on in several laboratories at present and is producing new evidence concerning relationships. This paper presents a revised classification of the primary subdivisions of the family—the subfamilies and tribes—in the light of the currently available information.

An earlier system (Grant 1959) was constructed before there was much pollen-morphological evidence or any DNA evidence. Both of these lines of evidence are very important for classification (see Materials and Methods for references). The two types of evidence were used in a recent system (Grant 1998; see Table 1).

I did not appreciate the full potential of the pollen evidence in 1998. It was used there to distinguish groups at low and middle taxonomic levels. In the revised system presented here it is used as a key character separating subfamilies.

An important molecular survey of the family was carried out by Johnson et al. (1996), using the chloroplast gene *matK* and a cladistic approach. This study recognized informal groupings based on the DNA cladograms, many of which differed from those in the Grant (1959) system. I took up some of these new groupings but rejected others in a revised taxonomic classification (Grant 1998, 1999; Grant & Day 1999). The taxonomic system of 1998–1999 differs significantly from the molecular cladistic groupings of Johnson et al. (1996).

Cladistic treatments of other organellar genes were made by various workers in this same period. The studies most relevant to this paper are listed in Materials and Methods. A complete list of molecular studies in the family up to 2000 is given by Porter and Johnson (2000).

Porter and Johnson (2000) then used the available molecular evidence as the main basis for a formal system of the family. The primary clades or deepest branchings in the DNA cladograms become subfamilies in their system, the secondary clades become tribes, and the third-order clades become genera or small sets of genera. Formal taxonomic names are assigned to the groups. Good descriptions of phenetic characters are given for the groups. However, it is difficult to tell what role these phenetic characters play in defining the groups; sets of diagnostic characters are lacking. The groups are basically clades. Porter and Johnson (2000, p. 55) describe their system as "a phylogenetic classification of the Polemoniaceae." It is what Mayr and Bock (2002) call a cladification.

Again, major differences exist between the cladistic system (Porter & Johnson 2000) and the taxonomic system (Grant 1998, 1999; Grant & Day 1999). A detailed analysis and discussion of these differences is given in Grant (2001). The incongruences persist in a comparison of the molecular cladistic system with the revised taxonomic system presented in this paper. Some of the differences are shown in Table 1.

TABLE 1. Comparison of recent classification systems of the family.

Grant 1959	Grant 1998, 1999; Grant and Day 1999
Tropical and subtropical taxa	**Subfam. 1. Cobaeoideae.**

	Tribe 9. Gi ieae.
	Gilia, Ipomopsis, Eriastrum, Langloisia, Tintinabulum.

Cladists, on finding differences between cladistic and taxonomic systems of the same group, commonly attribute the differences to inadequacies in the taxonomy. Johnson et al. (1996) expressed this view of the Grant (1959) system very clearly. Indeed, the 1959 system was old and in need of repair in 1996. However, there are also other explanations to consider.

The basic consideration is that one system is a product of taxonomy and the other a product of cladistics. The two approaches have different criteria, goals, and methods. Taxonomy groups organisms according to similarity and difference, cladistics groups them into ancestor-descendant lineages. Taxa are not the same as clades. Taxonomy uses the traditional definition of monophyly whereas cladistics uses a special definition of its own. In taxonomy a monophyletic group is any group of organisms descended from a recent common ancestor; in cladistics a group to qualify as monophyletic must contain all the descendants of the common ancestor (see reviews of Mayr & Bock 2002, and Grant 2003).

The differences in the definition of a systematic unit and of monophyly automatically lead to incongruence between taxonomic and cladistic systems of the same group. A group circumscribed in a given way can be monophyletic in taxonomy but non-monophyletic in cladistics. And cladists frequently and incorrectly declare a taxonomic group to be non-monophyletic when it is monophyletic by the taxonomic definition. Many of the disagreements between the taxonomic and cladistic systems of the Polemoniaceae (and other plant groups) can be attributed to the differences in working concepts and definitions (see Grant 2001, 2003).

Where incongruences between rival systems are due to the use of different working concepts, one system cannot be said to be right and the other wrong; both systems may be right by their own respective standards. The view held by many cladists, including Johnson et al. (1996) in the Polemoniaceae, that a new cladistic treatment should replace a preexisting taxonomic treatment, is not justified insofar as it is based on the working concepts. In fact, one could argue just the opposite. We should have both cladistic systems and up-to-date taxonomic classifications, so that consumers of systematic biology can have a choice.

Other incongruences between taxonomic and cladistic systems of the Polemoniaceae are due to the evidence used. Here we are comparing taxonomy with molecular cladistics, phenetic characters with DNA sequence variation, and broad databases with narrow ones. This aspect will be considered in the Discussion section.

An up-to-date formal taxonomic classification of the Polemoniaceae is needed to complement the valuable cladistic treatment of Porter and Johnson (2000). The present paper deals with the subfamilies and tribes. An updated taxonomic treatment of the genera and sections of the temperate herbaceous Polemoniaceae is also needed. Work has begun on selected temperate genera.

MATERIALS AND METHODS

I compiled a list of conventional taxonomic characters from the older literature. I then sorted out the characters that distinguish groups at higher levels in the family, and set aside those that are diagnostically useful for genera and species. Character expressions were checked in the University of Texas Herbarium where desirable.

Family-wide surveys of particular microscopic and chemical characters are very helpful. Such surveys are available for: chromosomes (Grant 1959, ch. 6); pollen (Stuchlik 1967a, 1967b; Taylor & Levin 1975); wood anatomy (Carlquist et al. 1984); corolla venation (Day & Moran 1986); flavonoids (Smith et al. 1977, 1982); and organellar DNA (several authors listed below). The older studies of chromosomes size (in Grant 1959) need to be repeated by modern methods of determining DNA quantity.

Some of the characters vary at the upper taxonomic levels, and are used in this paper, while others vary at the generic and infrageneric levels. This is illustrated by the flavonoids.

The flavonoids occurring in the family fall into three main groups: (A) the common types, kaempferol, quercetin, and myricetin; (B) 6-methoxyflavonols; and (C) C-glycosylflavones (Smith et al. 1977). Variation in these is more useful taxonomically at the genus level than at the tribal level, and only a part of the flavonoid evidence is included in this paper. Smith et al.'s (1977) findings are recorded below for the four tropical genera. One aspect, the presence or absence of types B and C is recorded below for the temperate tribes.

Numerous features of the pollen show variation within the family. Day and Moran (1986) found that the spatial distribution of the pores is especially useful diagnostically. Most members of the family fall into one or the other of two contrasting character states: pantoporate (pores scattered over the grain) or zonocolporate (pores equatorial).

The corolla tube has five sets of three parallel and separate veins, one set for each corolla lobe. In most members of the family the veins anastomose to form a network in the corolla throat or lobes. In the tribe Leptodactyloneae, however, the veins are non-anastomosing. The character may not be well exhibited in small-flowered species of other tribes (Day & Moran 1986).

Family-wide studies of DNA sequences have been carried out with chloroplasts (*matK*, *ndhF*), mitochondria (*nad1B*), and ribosomes (*ITS*) (Steele & Vilgalys 1994; Johnson et al. 1996; Porter 1997; Porter & Johnson 1998; Prather et al. 2000). The DNA relationships are clearly portrayed in the cladograms, and I have used these in constructing the taxonomic classification. However, I have not found a way to express the molecular evidence in verbal terms for inclusion in the descriptions. The Porter and Johnson (2000) system is a good representation of the molecular clades (see Table 1).

The molecular evidence is often but not always in agreement with the phenetic evidence. In cases of a conflict I reexamine the phenetic evidence with the thought that it is best to have some phenetic characters to support the molecular characters. In the recent past (Grant 1998, 1999) and again for the present study I have found some such correlated phenetic and molecular characters, and have made the appropriate taxonomic changes. If, however, molecular evidence alone points in one direction, while two or more reliable phenetic characters point to a different taxonomic conclusion, I follow the phenetics. In other words, I do not assume that the molecular evidence is always the right guide to follow.

The descriptions in the formal system consist mainly of the character states of diagnostic characters. These can be regarded as the evidence supporting the taxonomic groupings. Good complete descriptions are given by Porter and Johnson (2000).

The nomenclatural paragraphs of the subfamilies and tribes contain the essential original names and recent names. Additional synonyms may be found in Grant (1959).

SYSTEM OF CLASSIFICATION

Fam. Polemoniaceae Juss. Polemoniaceae (as Polemonia) Juss.; Gen. Pl. 136. 1789. TYPE: *Polemonium caeruleum* L.

Various life forms from small trees to annual herbs. Leaves mostly alternate, but opposite in *Phlox*, *Leptodactylon*, and *Linanthus*. Floral plan 5-5-5-3. Corolla sympetalous with epipetalous stamens, usually radial, sometimes bilateral. Corolla veins mostly anastomosing in the corolla throat or lobes, but non-anastomosing in *Leptodactylon* and *Linanthus*. Ovary superior and 3-carpellary. Fruit generally a 3-celled capsule, but 1- or 2-celled in some species of *Navarretia*. Original basic number $x = 9$; polyploids and aneuploids common.

Mainly American hemisphere; several species in Eurasia. About 347 species. These are grouped here into three subfamilies and nine tribes. The species are listed for the tropical and subtropical tribes and genera. This is not feasible for the species-rich temperate groups; for these see the species lists in Grant (1959) and Porter and Johnson (2000).

ANALYTICAL KEY TO TRIBES

1. Seeds mostly winged (sometimes wingless); chromosomes small; tropical and subtropical.
   2. Spiny desert shrub; deciduous green leaves in axils of spines; pollen zonocolporate; endemic in Baja California _____ **Acanthogilieae**
   2. Not spiny desert shrubs with leaves as above; pollen pantoporate; widespread in American tropics and subtropics.
      3. Calyx wholly herbaceous; individual flowers not subtended by bracts; life form varies.

4. Climbing vines; calyx sepals divided to base; leaves with terminal tendrils _____ **Cobaeeae**
4. Not vines; calyx synsepalous; leaves without tendrils.
5. Small trees and shrubs; Andes _____ **Cantueae**
5. Perennial herbs; Mexico and Guatemala _____ **Bonplandieae**

3. Calyx membranous with no or only small herbaceous regions; individual flowers subtended by bracts; shrubs and herbs _____ **Loeselieae**

1. Seeds without wings; chromosomes mostly medium-sized to large, but small in 1 tribe; temperate and boreal.
6. Pollen zonocolporate; seeds sandy or pale-colored; mostly in xeric habitats, common in deserts _____ **Gilieae**
6. Pollen pantoporate; seed color varies; in various habitats.
7. Seeds sandy or pale-colored; leaves opposite; leaves if cleft or divided are palmately so; chromosomes small _____ **Leptodactyloneae**
7. Seeds dark brown or black; leaves alternate or opposite; leaves if divided are pinnately so; chromosomes large or medium-sized.
8. Leaves alternate; leaves pinnately compound or lobed _____ **Polemonieae**
8. Leaves opposite, or absent in 1 small genus; leaves simple and entire _____ **Phlocideae**

Subfam. 1. Cobaeoideae (D. Don) Arn., Cobaeaceae D. Don, Edinburgh Philos. J. 10:109–111. 1824. Subfam. Cobaeoidea Arn., Encycl. Brittanica, ed. 7, 5:121. 1832. Subfam. Cobaeoideae Brand, Pflzr. 4(250):19. 1907. TYPE: *Cobaea scandens* Cav.

Various life forms from small trees to herbs, in tropical and subtropical zones. Seeds mostly winged, sometimes wingless. Pollen pantoporate. Chromosomes small.

Tribe 1. Cantueae Peter, Nat. Pflazfam. 4(3a):45. 1891. TYPE: *Cantua buxifolia* Juss.

Small trees and shrubs. Leaves simple with broad blade or pinnately divided and narrow. Calyx wholly herbaceous and synsepalous. Corolla radial to bilateral. Seeds flat with broad wings. All three groups of flavonoids (A, B, and C) present (see Materials and Methods for explanation of these groups). $2n = 54$.

Distribution and taxa.—Andes. One genus, *Cantua*, with twelve species: *C. bicolor*, *C. buxifolia*, *C. candelilla*, *C. coerulea*, *C. cuzcoensis*, *C. flexuosa*, *C. longiflora*, *C. longifolia*, *C. ovata*, *C. pyrifolia*, *C. quercifolia*, *C. tomentosa*. The former small genus *Huthia* has been submerged in *Cantua* by Porter and Johnson (2000) and Alan Prather (pers. comm.) who is currently studying the group. I am following these authors.

Tribe 2. Cobaeeae (D. Don) Meisn., Cobaeaceae D. Don, Edinburgh Philos. J. 10:109–111. 1824. Tribe Cobaeeae Meisn., Pl. Vasc. Gen. 180, 273. 1839–1840. TYPE: *Cobaea scandens* Cav.

Climbing vines. Leaves pinnately compound with a terminal tendril. Flowers large and solitary. Calyx wholly herbaceous, sepals divided to base. Corolla radial. Seeds flat with broad wings. Has flavonoids of type A only. $2n = 52$.

Distribution and taxa.—Tropical forests from Mexico to Peru. One genus, *Cobaea*, with four sections and eighteen species: *C. aequatoriensis*, *C. ascher-*

soniana, *C. biaurita*, *C. campanulata*, *C. flava*, *C. gracilis*, *C. lutea*, *C. minor*, *C. pachysepala*, *C. paneroi*, *C. penduliflora*, *C. pringlei*, *C. rotundiflora*, *C. scandens*, *C. skutchii*, *C. stipularis*, *C. trianae*, *C. triflora*. See the recent monograph of Prather (1999).

Tribe 3. Bonplandieae Baill., Hist. Pl. 10:342. 1890. TYPE: *Bonplandia geminiflora* Cav.

Subshrubs with woody base and herbaceous shoot. Leaves simple with a broad blade and serrate margin or lobed. Calyx wholly herbaceous and synsepalous. Corolla bilateral. Seeds plump with narrow wings or wingless. Has flavonoids of type B only. $2n = 30$.

Distribution and taxa.—Mexico and Guatemala. One genus, *Bonplandia*, with two species, *B. geminiflora* and *B. linearis*.

Tribe 4. Loeselieae J.M. Porter & L.A. Johnson, Aliso 17:84. 8 Jun 1998. Tribe Loeselieae V.E. Grant; Amer. J. Bot. 85:744. 17 Jun 1998. TYPE: *Loeselia ciliata* L.

Subshrubs, perennial herbs, and annuals. Leaves simple with broad blade and entire or serrate margin. Inflorescence bracts with prominent veins subtend individual flowers; these are usually large and leaflike, but may be small. Calyx synsepalous and membranous with no or only small herbaceous regions. Corolla radial or bilateral. Seeds with narrow wings or wingless. Flavonoid groups A and C present, but type B absent. $2n = 18$.

Distribution and taxa.—Mexico to southern Texas and Arizona and to northern South America. Often in the temperate zone of tropical mountains. One genus, *Loeselia*, with fifteen species: *L. amplectens*, *L. caerulea*, *L. ciliata*, *L. cordifolia*, *L. glandulosa*, *L. grandiflora*, *L. greggii*, *L. hintoniorum*, *L. involucrata*, *L. mexicana*, *L. nepetifolia*, *L. pumila*, *L. purpusii*, *L. rupestris*, *L. rzedowski*. See Turner (1994) for a recent generic treatment.

Subfam. 2. Polemonioideae Brand., Pflzr. 4(250):30. 1907. TYPE: *Polemonium caeruleum* L.

Subshrubs, perennial herbs, and annuals, of temperate and boreal zones. Seeds not winged. Pollen pantoporate. Chromosomes mostly large or medium-sized, but small in one tribe.

Tribe 5. Polemonieae Arn., Encycl. Brittanica, ed. 7, 5:121. 1832. Tribe Polemonieae Meisn., Pl. Vasc. Gen. 273. 1839. TYPE: *Polemonium caeruleum* L.

Perennial and annual herbs. Leaves alternate. Leaves pinnately compound (in *Polemonium*) or simple and pinnately lobed, or simple and entire in reduced forms (in the other genera). Capsule locules commonly containing 1 to few seeds each; sometimes many-seeded in *Navarretia*. Seeds dark brown or black, sometimes plump and rounded, sometimes small. Pollen generally pantoporate, but

zonocolporate in some species of *Collomia*. Flavonoids of type C absent; type B absent in *Polemonium* and *Allophyllum*, but present in *Collomia* and *Navarretia*. Chromosomes medium-sized or large, $x = 9$ and 8.

Distribution and taxa.—North America, extending to Eurasia. Genera: *Polemonium*, *Collomia*, *Allophyllum*, *Navarretia*. About 78 species.

Polemonium is set apart from the other three genera by leaf form and some molecular characters (Johnson et al. 1996). It could well be separated in a tribe of its own, as in the Porter and Johnson (2000) system. On the other hand, it is allied to the other genera by seed and pollen characters and by other molecular evidence (Prather et al. 2000). A conservative disposition is made here.

Tribe 6. Phlocideae Dumort., Anal. Fam. Pl., 25. 1829. Gruppe Phloginae Rchb., Handb. Nat. Pflzsystems, ed. 1, 194. 1837. Tribe Phlogieae Rohb. ex J.M. Porter & L.A. Johnson, Aliso 17:84. 1998. TYPE: *Phlox glaberrima* L.

Subshrubs, perennial herbs, and some annuals. Leaves or at least the lower leaves opposite; true leaves absent in the small genus *Gymnosteris*. Leaves simple with narrow blade and entire margin. Capsule locules mostly 1-seeded. Seeds brown, sometimes plump and rounded, sometimes small. Flavonoids of type B lacking, but type C present. Chromosomes medium-sized or large, $x = 7$ and 6.

Distribution and taxa.—North America, extending to Asia. Genera: *Phlox*, *Microsteris*, *Gymnosteris*. About 66 species.

Phlox (x = 7) could be derived from *Collomia* (x = 8) in the Polemonieae. *Microsteris* (x = 7) is a reduced annual derived from a perennial *Phlox*. *Gymnosteris* ($x = 6$) is a reduced leafless annual formerly thought to be close to *Collomia*; but phenetic and molecular evidence now indicate that its closest relative is *Phlox* or *Microsteris* (Porter & Johnson 2000). See Ferguson and Jansen (2002) on molecular relationships in *Phlox*.

Tribe 7. Leptodactyloneae V.E. Grant, Amer. J. Bot. 85:746. 1998. TYPE: *Leptodactylon californicum* Hook & Arn.

Subshrubs, perennial herbs, and annuals. Leaves mostly opposite. Leaves palmately divided, or simple and entire in reduced forms. Corolla veins non-anastomosing, in contrast to other tribes (see explanation in Materials and Methods). Capsule locules containing several to many seeds each, rarely 1-seeded. Seeds sandy or pale-colored, or sometimes brown in *Leptodactylon*. Flavonoids of types B and C present. Chromosomes small, $x = 9$.

Distribution and taxa.—Semiarid and arid habitats including deserts in western North America. Genera: *Leptodactylon*, *Linanthus*, *Maculigiia*. About 50 species.

In the system of Porter and Johnson (2000), *Linanthus* s.l. is subdivided into two genera, *Linanthus* s.s. and *Leptosiphon*, on cladistic grounds. These two taxa are indeed well differentiated, but they are also united by some common characters, and they could be treated as either subgenera of one genus or two

separate genera. A conservative treatment as *Linanthus* s.l. is preferred here because it shows the relationships of the two branches. *Maculigilia* is a recent segregate genus for the old distinctive desert species *Gilia maculata* (see Patterson 1989; Grant 1999). *Maculigilia maculata* is probably a derivative of some xerophytic member of *Linanthus*.

Leptodactylon and *Linanthus* form a closely related and isolated genus pair. This group was formerly placed in the tribe Gilieae on macroscopic characters (Grant 1959), but the more recent evidence of flavonoids and *cpDNA* and *nrDNA* point to a relationship with *Phlox* (Smith et al. 1977, 1982; Johnson et al. 1996; Porter 1997). *Leptodactylon/Linanthus* is placed in the tribe Phlocideae in the Porter and Johnson (2000) system.

However, in other characters, *Leptodactylon* and *Linanthus* are unlike the Phlocideae (or Polemonieae); namely, palmate leaves, non-anastomosing corolla veins, sandy or pale-colored seeds, small chromosomes, and an affinity for semiarid and arid habitats. The present treatment attempts to resolve the similarities and important differences by placing these genera in a separate tribe Leptodactyloneae next to the Phlocideae. This makes for a better definition of both tribes.

Subfam. 3. Acanthogilioideae (V.E. Grant) J.M. Porter & L.A. Johnson, Aliso 19:60. 2000. Tribe Acanthogilieae V.E. Grant; Amer. J. Bot. 85:744. 1998. TYPE: *Gilia gloriosa* Brand., *Acanthogilia gloriosa* A.G. Day & R. Moran.

Shrubs, subshrubs, and herbs of arid habitats, commonly in deserts. Seeds winged or wingless. Pollen zonocolporate. Chromosomes mostly medium-sized or large, but small in one tribe.

Tribe 8. Acanthogilieae V.E. Grant, Amer. J. Bot. 85:744. 1998. TYPE: *Gilia gloriosa* Brand., *Acanthogilia gloriosa* A.G. Day & R. Moran.

Spiny desert shrub. Leaves dimorphic, with primary leaves modified as persistent spines, and small deciduous green leaves in the axils of the spines. Capsule locules containing 1–6 seeds each. Seeds flat with broad wings. Chromosomes small, $x = 9$.

Distribution and taxa.—Endemic in central Baja California. One genus and species *Acanthogilia gloriosa*. Detailed information about this interesting taxon is given by Day and Moran (1986).

Tribe 9. Gilieae (Rchb.) V.E. Grant, Nat. Hist. Phlox Fam. 120. 1959. Gruppe Gilieae Rchb.; Handb. Nat. Pflzsystems, ed. 1, 194, 1837. Tribe Gilieae J.M. Porter & L.A. Johnson; Aliso 19:63. 2000. TYPE: *Gilia laciniata* Ruiz & Pav.

Subshrubs, perennial herbs, and annuals; not spiny. Leaves not dimorphic; leaves pinnately divided or dissected with narrow segments, or small and linear in reduced forms. Capsule locules usually many-seeded. Seeds sandy or pale-colored, mostly angular, sometimes banana-shaped. Pollen generally

zonocolporate, but deviating toward pantoporate in some species of *Eriastrum*. Flavonoids of type B present; type C uncommon (occurs in *Gilia* and *Langloisia*) or absent (*Gilia*, *Ipomopsis*). Chromosomes mostly medium-sized, sometimes large; $x = 9$, 8, and 7.

Distribution and taxa.—Widespread in arid habitats, common in deserts. The genera as treated here are *Gilia*, *Tintinabulum*, *Ipomopsis*, *Eriastrum*, *Langloisia*. About 105 species.

A broad concept of *Gilia* as a genus composed of six sections is adopted here and elsewhere (Grant 1999, 2001). Gilia s.l. with a basic chromosome number of $x = 9$ in all sections (and $x = 8$ in part of one section) is basal in the tribe. *Tintinabulum* ($x = 9$) is a small specialized genus close to *Gilia*. *Ipomopsis*, *Eriastrum*, and *Langloisia* with $x = 7$ appear to be derivatives of *Gilia* (Grant 2001).

Molecular cladists consider *Gilia* s.l. to be polyphyletic, and split it up into a series of small genera (Johnson et al. 1996; Porter & Johnson 2000). I contend that this viewpoint is based, first, on the cladistic definition of monophyly and, second, on an overreliance on the molecular cladograms, and that *Gilia* s.l. is monophyletic by the traditional definition of monophyly (Grant 1999, 2001).

PHYLOGENY

The Polemoniaceae is evidently derived from an ericalean stock (Brown 1938; Porter & Johnson 1998; Johnson et al. 1999). The basal living forms of the family are the tropical and subtropical genera. There are five of these (*Cantua*, *Cobaea*, *Bonplandia*, *Loeselia*, *Acanthogilia*), all very different from one another. In this group *Cantua* comes closest to the ericalean stock, while the other genera exhibit derived characters of one sort or another.

The subtropical desert shrub, *Acanthogilia*, differs markedly from *Cantua*, but also shares some inconspicuous but significant characters with it (Day & Moran 1986). These workers suggest (p. 125) that "*Acanthogilia* may be a specialized desert descendant of a diploid line also ancestral to *Cantua*."

One of the significant characters is the spatial distribution of pores on the pollen grains, whether pantoporate or zonocolporate. Another is ecological preferences: mesic or xeric. The pollen pore character has proven to be a valuable marker for revising the classification of species groups and genera (Day & Moran 1986; Grant & Day 1999), and can be extended to higher taxa. *Cantua* and three related genera (*Cobaea*, *Bonplandia*, and *Loeselia*, comprising the subfamily Cobaeoideae) are pantoporate and mesophytic. *Acanthogilia* is zonocolporate and xerophytic. Day and Moran's (1986) hypothesis can be rephrased as the suggestion of an early split between the ancestors of the pantoporate Cobaeoideae and the ancestor of the zonocolporate *Acanthogilia*. The molecular evidence of Prather et al. (2000) is in agreement with this hypothesis.

This split persists in the derived, temperate, mainly herbaceous tribes. Day

and Moran (1986) point to characters which *Gilia* and its close relatives share with *Acanthogilia*. The tribe Gilieae, as circumscribed here and in Grant (1998), is zonocolporate and xerophytic. It could well have an unknown ancestor in common with *Acanthogilia*.

The mid-Eocene plant *Gilisenium* from Utah is close to *Gilia* in a number of characters (Lott et al. 1998). It is desirable to determine its pollen pore character, if possible.

The tribes Polemonieae and Phlocideae are pantoporate and generally mesophytic. They may be derived from a *Bonplandia*-like ancestor in the Cobaeoideae. The Polemonieae and Phlocideae extend into cold northern areas and are the only representatives of the family in northeastern North America and Eurasia. The Leptodactyloneae is also pantoporate and is related to the Phlocideae but is xerophytic.

The two main temperate phylads often occur in the same area, especially in western North America, where some species or groups have crossed over from one type of habitat to another. In this situation the two phylads have given rise to species of annuals which converge in their general morphological characters. For example, some small-flowered species of *Allophyllum* (Polemonieae) closely resemble certain small-flowered species of *Gilia* (Gilieae), and were mistakenly treated as *Gilia* until recently (Grant 1999; Grant & Day 1999).

DISCUSSION

Several causal factors contribute to the numerous differences between the taxonomic and molecular cladistic systems of the Polemoniaceae. Two of these are theoretical: (1) the use of different systematic units, namely, taxa and clades; and (2) the application of different definitions of monophyly. These two factors were discussed in the introduction. The two approaches also use different evidence and this of course leads to different results. We will consider here: (3) differences in the types of characters used; and (4) differences in the range and breadth of the database.

(3) Molecular systematists working in the Polemoniaceae (and other plant groups) use DNA sites in chloroplasts and mitochondria, which are parts of the cytoplasmic genome. Phenetic characters used in taxonomy are determined mainly by the chromosomal genome (see Grant 1975, 2003, for review). Discordance between plastid and mitochondrial evidence, on the one hand, and phenetic characters on the other, can be expected and is often found. Ribosomes, also used in molecular systematics of Polemoniaceae and other families, are a part of the chromosomal genome. They can vary independently of plastids and mitochondria, and for that matter, independently of unlinked chromosomal genes. Here again, incongruence between the various sources of evidence can be expected (see Grant 2003, for further discussion).

(4) Molecular cladistic treatments of the Polemoniaceae (and those of other

plant groups) are based on one or a few genes. The treatment of Johnson et al. (1996) blocks out informal systematic groups on the basis of one chloroplast gene. Taxonomic systems, by contrast, are based on numerous phenetic characters determined by scores or hundreds of genes and gene systems (Grant 1975, for review). These contrasts between approaches represent the extremes. Modern taxonomists utilize the DNA evidence of molecular systematists. And many molecular cladists incorporate phenetic characters in reaching their conclusions.

Factors (1) and (2) bring about different results but do not affect the accuracy of the results, as noted in the introduction. The type and range of characters (factors 3 and 4) do have an effect on the robustness of the results. Molecular cladograms are essentially gene trees, or character phylogenies to use an older term. Single characters often work well in one part of a group but break down elsewhere in the same group. If the goal is a natural classification of whole organisms, one must assemble a broad range of characters, some of which may conflict with others, and one should then follow the weight of the evidence, as is standard procedure in taxonomy.

Taxonomic classifications thus have certain methodological advantages. Another advantage lies in the area of convenience and desirability. Named similarity groups, and hierarchies of such groups, are generally useful for identification, information retrieval, and cataloging. It would be difficult to write a flora, using clades instead of taxa, and such a flora would be difficult to use if it were written (see Diggs & Lipscomb 2002).

For several reasons, therefore, it is desirable to make an updated taxonomic classification of the Polemoniaceae available. But why stop with the Polemoniaceae. Numerous other plant groups have been revised recently by molecular cladistic methods, but are represented in the literature by old taxonomic treatments. These groups should also be re-revised by taxonomists, using the new molecular evidence, but handling all the evidence by taxonomic methods. Plant taxonomy has much work to do.

ACKNOWLEDGMENTS

I discussed the problem with Billie L. Turner, Tom Wendt, and Karen A. Grant. J. Mark Porter and Carolyn J. Ferguson read the manuscript. The help of these colleagues is greatly appreciated.

BOOK NOTICES

MILO I. HARPSTEAD, THOMAS J. SAUER, and WILLIAM F. BENNETT. 2001. **Soil Science Simplified, 4th edition.** (ISBN 0-8138-2942-9, hbk.). Iowa State Univ. Press, 2121 South State Ave., Ames, Iowa 50014, U.S.A (Orders: 800-862-6657, www.isupress.com). $42.95, 225 pp., numerous b&w drawings and half-tones, 6" × 9".

This book is suitable as an undergraduate text or as a reference for biologists or other scientists not trained in soil science. It systematically covers the physical, biological and chemical properties of soils; soil formation, soil water, heat flow, and fertility; soil classification and surveys; and soil management, conservation, and engineering. I found the chapters on soil colloids and chemistry, soil classification, and soil surveys the most helpful in interpreting soil maps and characteristics. The different types of clays and their characteristics are explained. Also, the various word roots, prefixes and suffixes used in the names of soil classes and subclasses are explained. It includes a glossary and index.

The weakest aspect of the book is the quality of the illustrations. In many figures, the lines are excessively heavy, black, and run-together. Many of the drawings are not well-executed and fail to show the described features. As a result, much space is wasted that could have been better used by replacing with text or photographs.—*Roger W. Sanders, Associate Collections Manager, Botanical Research Institute of Texas, 509 Pecan St, Fort Worth, TX 76102-4060, U.S.A., rsanders@brit.org.*

WILHELMINA FEEMSTER JASHEMSKI and FREDERICK G. MEYER (eds.). 2002. **The Natural History of Pompeii.** (ISBN 0-521-80054-4, hbk.). Cambridge University Press, The Edinburgh Building, Cambridge CB2 2RU, UK; 100 Brook Hill Drive, West Nyack, NY 10994-2133, U.S.A. (Orders: 845-353-7500, 845-353-4141 fax, http://www.cup.org/). $170.00, 502 pp., 387 figs. (b/w, color, drawings, etc.), 9" × 12".

From the dustjacket.—"This volume brings together the work of geologists, soil specialists, paleobotanists, botanists, paleontologists, biologists, chemists, dendrochronologists, ichthyologists, zoologists, ornithologists, mammologists, herpetologists, entomologists, and archaeologists, affording a thorough picture of the landscape, flora and fauna of the ancient sites. The detailed and rigorously scientific catalogues, which are copiously illustrated, provide a checklist of the flora and fauna upon which future generations of scholars can continue to build."

The catalogue of plants by Wilhelmina F. Jashemski, Frederick G. Meyer, and Massimo Ricciardi enumerates and discusses in detail 184 plants. The chapter is 101 pages. The evidence for the plant list comes primarily from the urban sites Pompeii and Herculaneum, and a few villas, which give a good picture of the popular ornamental plants that adorned the many home gardens, parks, and other public places, as well as plants that had religious significance and those used for medicine and other purposes, especially food. There is an extensive list of references. This is an impressive work that will be of interest a variety of audiences.—*Barney Lipscomb, Botanical Research Institute of Texas, 509 Pecan St, Fort Worth, TX 76102-4060, U.S.A., barney@brit.org.*

A SYNOPSIS OF *MACHAERANTHERA* (ASTERACEAE: ASTEREAE), WITH RECOGNITION OF SEGREGATE GENERA

ABSTRACT

Recent investigations of *Machaeranthera* s.l. incorporating molecular, morphological, cytological, and chemical evidence have supported relationships that do not conform to any recent circumscription of the genus. To bring the classification of *Machaeranthera* more in line with current understanding of its evolutionary history, revisions to its taxonomy are proposed. *Machaeranthera* is circumscribed to include two species, and other species that have been included in *Machaeranthera* are apportioned into three additional genera. *Dieteria* is revived to accommodate three of these species, *Xanthisma* is expanded to accomodate 16 more species, and the new genus *Arida* is proposed for those remaining. New combinations for the species in *Dieteria*, *Xanthisma*, and *Arida* are provided.

RESUMEN

Investigaciones recientes en *Machaeranthera* s.l. que incluyen datos moleculares, morfológicos, citológicos, y químicos dan como resultado unas relaciones que no concuerdan con ninguna circunscripción reciente del género. Para poner la clasificación de *Machaeranthera* más en línea con el conocimiento actual de su historia evolutiva, se proponen revisiones de su taxonomía. *Machaeranthera* se circunscribe para incluir dos especies, y otras especies que se habían incluido en *Machaeranthera* se redistribuyen en tres géneros adicionales. *Dieteria* se rescata para acomodar tres de estas especies, *Xanthisma* se expande para incluir 16 especies más, y se propone el nuevo género *Arida* para las restantes. Se realizan las nuevas combinaciones para las especies de *Dieteria*, *Xanthisma*, y *Arida*.

The genus *Machaeranthera* Nees (Asteraceae: Astereae) was established to accommodate the single species *M. tanacetifolia* Nees. Since its inception, many different circumscriptions of *Machaeranthera* have been proposed, and the genus has included various parts of several other genera, with little agreement on its composition or its relationships with other taxa (see Morgan and Simpson 1992 for a more detailed taxonomic history).

The most recent published treatment of *Machaeranthera* was by Hartman (1990), who included 36 species in the genus, excluding several taxa that are now placed in the genera *Hazardia* Greene (Hartman 1990), *Rayjacksonia* R.L. Hartman & M.A. Lane (Lane & Hartman 1996), *Tonestus* A. Nelson (Nesom 1991), and *Xylorhiza* Nutt. (Hartman 1990). The circumscription of *Machaeranthera* adopted by Hartman (1990) included species with both cyanic (white, blue, pink, purple) and yellow rays, and apportioned them into two subgenera and eight sections. We will refer to this circumscription as *Machaeranthera* s.l.

SIDA 20(4): 1387–1416. 2003

Investigations of *Machaeranthera* s.l. using molecular evidence have helped to clarify its systematics. Restriction site data from chloroplast DNA (cpDNA) indicated that *Machaeranthera* section *Psilactis* (A. Gray) Turner & Horne was not a close relative of *Machaeranthera* s.l. (Morgan & Simpson 1992; Morgan 1993). This section was removed from *Machaeranthera* s.l. by Morgan (1993), leaving 30 species in the genus. More recent investigations of *Machaeranthera* (sensu Morgan 1993) employed DNA sequence data from nuclear ribosomal DNA internal and external transcribed spacers (nrDNA) (Morgan 1997; Morgan 2003). Comparison of this evidence with cpDNA data indicated that the evolution of *Machaeranthera* and its relatives has been complex, involving as many as seven occurrences of reticulate evolution. The molecular evidence also indicated that other genera (e.g., *Oönopsis* Nutt., *Pyrrocoma* Hook., and *Xanthisma* DC.) are closely related to various parts of *Machaeranthera* (Fig. 1).

The relationships supported by a combination of molecular, morphological, cytological, and chemical evidence do not support any recent circumscription of *Machaeranthera*. Therefore, a new classification is needed to bring the taxonomy of the genus more in line with current understanding of its relationships. A case could be made for including *Oönopsis* and *Pyrrocoma* in an expanded *Machaeranthera*, and cpDNA evidence provides some support for such a treatment (Fig. 1). However, nrDNA data do not support this circumscription (Fig. 1). Furthermore, we contend that enlarging *Machaeranthera* through accretion would obscure the phylogenetic patterns within the complex, and would result in a large, heterogenous, and unwieldy genus that would be difficult to characterize satisfactorily. We therefore propose that *Machaeranthera* (sensu Morgan 1993) be divided into four genera, as described below.

KEY TO THE GENERA TREATED HERE

1. Ray floret corollas yellow (heads radiate) _____ **Xanthisma**
1. Ray floret corollas white (sometimes yellowish on drying), pink, red-purple, or purple, or heads eradiate.
   2. Leaves deeply pinnatifid to bipinnatifid throughout, at least many of the teeth and lobes sharply acute with bristle tips, bristles 0.2–1 mm long; plants annual; pappus of subulate bristles, dorsi-ventrally flattened near base, bases overlapping _____ **Machaeranthera**
   2. Leaves entire to toothed or lobed, if pinnatifid to bipinnatifid throughout then lobes often rounded, with or without an apiculum but not bristle tipped; plants annual to strongly perennial; pappus of filiform to subulate bristles, terete to flattened near base, bases overlapping or not overlapping.
      3. Plants strongly perennial with a branched caudex (taprooted, sometimes biennial in *Xanthisma gymnocephalum*, central Mexico); receptacles covered with scales 0.3 3 mm long, often forming an alveolate reticulum; pappus bristles subulate, flattened near base, bases strongly overlapping _____ **Xanthisma**
      3. Plants taprooted annuals or short lived perennials (forming vegetative rosettes in *Arida blepharophylla*, a species also exceptional, as indicated, in the following characters); receptacles usually naked (or scales rarely to 0.5 mm

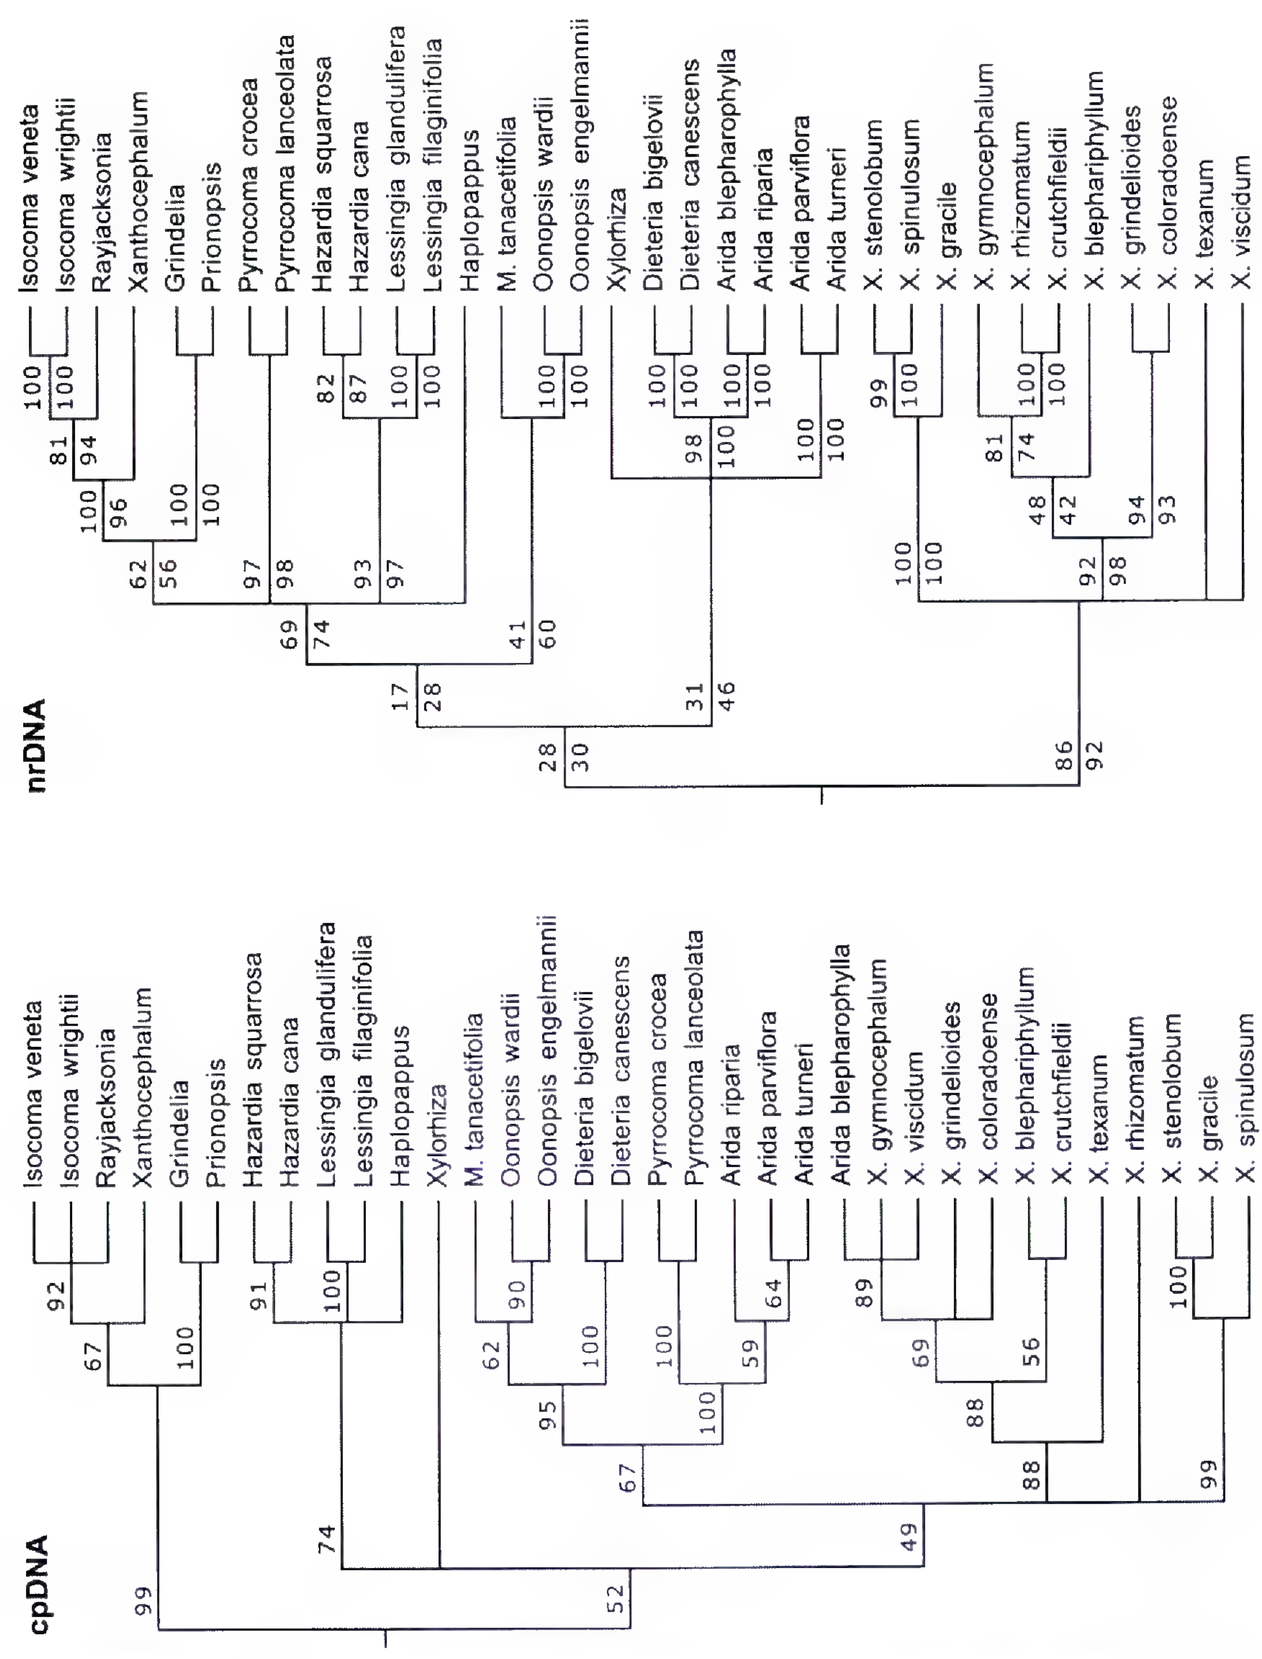

FIG. 1. Strict consensus trees resulting from analysis of chloroplast DNA restriction site data (cpDNA) and combined ITS and ETS sequence data (nrDNA) of *Machaeranthera* and related taxa, from Fig. 3 of Morgan (2003) with modified nomenclature. Bootstrap percentages are shown above and below the branches; values above the branches on both phylogenies are from unweighted bootstrap analysis, and values below the branches on the nrDNA phylogeny are from analyses in which transversions were weighted two times transitions. Generic names for the species of *Machaeranthera* sensu Morgan (1993) conform to the treatment proposed in this paper. Genus names for species of *Machaeranthera* and *Xanthisma* are abbreviated "M." and "X.," respectively.

long); pappus bristles filiform, not flattened near base (or slightly so), bases not (or slightly) overlapping.

4. Ray florets with prominent pappus (often eradiate in the glandular-pubescent *D. canescens* var. *shastensis*); leaves entire to toothed and plants variously pubescent with glandular and/or nonglandular hairs; mountains, plains, and basins of W U.S.A.; SW Canada; extreme N Mexico _____ **Dieteria**

4. Ray florets with pappus absent (5 species; eradiate in the glabrous *A. carnosa*) or present; if pappus present then leaves pinnatifid to bipinnatifid throughout or (if leaves entire to toothed) plants glabrous except for bristles or apiculate or bristle tipped teeth on leaf margins; deserts of SW U.S.A.; Mexico _____ **Arida**

Machaeranthera Nees, Gen. & Sp. Asterearum 224. 1832. TYPE: *Aster tanacetifolius* Kunth.

Chrysopsis subgenus *Pappochroma* Nutt., J. Acad. Nat. Sci. Phila. 7:34. 1834. *Dieteria* subgenus *Pappochroma* (Nutt.) Nutt., Trans. Amer. Philos. Soc. 7:302. 1840. *Dieteria* section *Pappochroma* (Nutt.) Walpers, Rep. Bot. Syst. 2:587. 1843. TYPE: *Chrysopsis coronopifolia* Nutt.

Aster section *Machaeranthera* (Nees) Benth. & Hook., Gen. Pl. 2:272. 1873. *Aster* subgenus *Machaeranthera* (Nees) A. Gray, Proc. Amer. Acad. Arts 16:99. 1880.

Machaeranthera series *Verae* Cronquist & D.D. Keck, Brittonia 9:238. 1957, nom. illeg. (ICBN: 52.1).

Herbs taprooted annuals or biennials, 5–100 cm tall. **Stems** erect to ascending, much branched when well developed, moderately to densely pubescent with glandular and nonglandular hairs. **Leaves** alternate; pinnatifid or bipinnatifid, deeply lobed or dissected, moderately to densely pubescent with glandular and nonglandular hairs, apices, including lobes and teeth, mucronate to bristle tipped, bristles if present 0.2–1 mm long. **Heads** radiate. **Involucres** broadly turbinate to hemispheric. **Phyllaries** in 3–6 imbricate series, graduated in length, appressed, spreading, or reflexed, moderately to densely pubescent with glandular and nonglandular hairs; bases indurate, apices herbaceous. **Receptacles** alveolate, flat to convex, naked or with scales to 0.4 mm long. **Ray florets** pistillate, fertile; corollas blue, violet, or purple. **Disc florets** bisexual, fertile, corollas yellow, narrowly funnelform; tubes and limbs glabrous or glabrate, lobes 0.3–1 mm long, glabrous to pubescent. **Cypselae** of ray and disc florets distinctly dimorphic, narrowly to broadly obovate, sparsely to densely pubescent; moderately thick walled, with 4–9 ribs per face, 2.4–3.8 mm long, those of ray florets ~3 sided, rounded abaxially, of disc florets somewhat compressed laterally; pappus white to tawny, of ray florets 1/2 to nearly equalling length of disc florets; bristles coarsely barbellate, in 1–3 series, dorsi-ventrally flattened and dissimilar in width near base, bases overlapping, mostly 4.5–6.5 mm long. $n = 4$.

The circumscription of *Machaeranthera* adopted here results in a genus of two species. We apportion the remaining 28 species of *Machaeranthera* (sensu Morgan 1993) to *Dieteria*, *Xanthisma*, and *Arida* (see below). The three species placed in *Dieteria* could potentially also be included in *Machaeranthera* because of a number of similarities. All members of the two genera produce flavonols, and all have chromosome numbers of $n = 4$, obovate fruits, and nar-

row phyllaries that are often reflexed (Hartman 1976, 1990; Turner 1987). This relationship was also supported by cpDNA evidence (Fig. 1). However, nrDNA evidence conflicted with cpDNA (Fig. 1), and the substantial conflict between them complicates the issue by suggesting reticulate evolution in the ancestors of *Machaeranthera*, *Dieteria*, or both. In addition, cpDNA and nrDNA evidence both supported a close relationship between *Machaeranthera* and *Oönopsis*, and expansion of *Machaeranthera* to include *Dieteria* would also have to include *Oönopsis*, which differs from *Machaeranthera* in many ways (Morgan & Simpson 1992). Additional synonymy for *Machaeranthera* is included in Turner (1987).

KEY TO THE SPECIES OF *MACHAERANTHERA*

1. Involucres hemispheric; herbaceous phyllary apices spreading to reflexed; disc corolla lobes mostly 0.3–0.7 mm long, glabrous or glabrate _____ **1. Machaeranthera tanacetifolia**

1. Involucres broadly turbinate; herbaceous phyllary apices appressed; disc corolla lobes mostly 0.7–1 mm long, pubescent _____ **2. Machaeranthera tagetina**

1. Machaeranthera tanacetifolia (Kunth) Nees, Gen. & Sp. Asterearum 225. 1832. *Aster tanacetifolius* Kunth, Nov. Gen. & Sp., ed. folio, 4:74. 1820. *Aster chrysanthemoides* Willd. ex Spreng., Syst. Veg. 3:538. 1826. TYPE: MEXICO: "Colitur in horto Mexicano," s.d., *Humboldt s.n.* (HOLOTYPE: P nv., IDC microfiche 6209. 97.III.6; possible ISOTYPE: B-W; PHOTOISOTYPE: TEX!).

Chrysopsis coronopifolia Nutt., J. Acad. Nat. Sci. Phila. 7:34. 1834. *Dieteria coronopifolia* (Nutt.) Nutt., Trans. Amer. Philos. Soc., ser. 2, 7:302. 1840. *Machaeranthera coronopifolia* (Nutt.) A. Nelson, Bot. Gaz. 37:268. 1904. TYPE: U.S.A. NORTH DAKOTA: "Towards the sources of the Missouri" (probably near Fort Mandon), Jul–Aug 1811, *Nuttall s.n.* (ISOTYPE: GH; probable ISOTYPE: NY).

2. Machaeranthera tagetina Greene, Pittonia 4:71. 1899. *Aster tagetinus* (Greene) S.F. Blake, Contr. U.S. Natl. Herb. 25:263. 1925. TYPE: U.S.A. ARIZONA. Cochise Co.: near Fort Huachuca, 1891, *Wilcox s.n.* (HOLOTYPE: US).

Dieteria Nutt., Trans. Amer. Philos. Soc., ser. 2, 7:300. 1840. LECTOTYPE, here designated: *Aster canescens* Pursh.

Machaeranthera section *Hesperastrum* A. Gray, Proc. Amer. Acad. Arts 6:539. 1865. *Aster* subgenus *Hesperastrum* (A. Gray) A. Gray, Proc. Amer. Acad. Arts 16:97. 1880. *Aster* section *Hesperastrum* (A. Gray) A. Gray, Syn. Fl. N. Amer. 1(2):174. 1884. TYPE: *Machaeranthera shastensis* A. Gray.

Machaeranthera subgenus *Dieteria* (Nutt.) Greene, Pittonia 3:59. 1896.

Machaeranthera series *Variabiles* Cronquist & D.D. Keck, Brittonia 9:237. 1957, nom. illeg. (ICBN: 24.3).

Herbs taprooted annuals, biennials, or perennials, 10–100 cm tall. **Stems** erect to ascending, much branched when well developed, glabrous to variously pubescent with glandular and/or nonglandular hairs. **Leaves** alternate; entire to irregularly serrate or dentate, moderately to densely pubescent with glandular

and/or nonglandular hairs, apices, including lobes and teeth, spinescent due to indurated apiculae, bristles absent. **Heads** radiate or eradiate. **Involucres** turbinate, campanulate, or hemispheric. **Phyllaries** in 3–12 imbricate to subimbricate series, graduated in length, appressed, spreading, or reflexed, glabrous or variously pubescent with glandular and/or nonglandular hairs; bases indurate, apices herbaceous, margins scarious. **Receptacles** alveolate, convex, naked or scales to 0.3 mm long. **Ray florets** pistillate, fertile (sterile or absent in *D. canescens* var. *shastensis*); corollas white, blue, violet, or purple. **Disc florets** bisexual, fertile, corollas yellow, ± funnelform, tubes and limbs glabrous or glabrate, lobes 0.2–0.7 mm long, glabrous to minutely pubescent. **Cypselae** of ray and disc florets somewhat dimorphic, linear to obovate, glabrous to moderately pubescent; thin walled, smooth or with 4–6 ribs per face, 3–6 mm long, those of ray florets generally flattened, rounded abaxially, of disc florets flattened laterally; pappus white to brown or reddish brown, of ray florets 2/3 to nearly equalling length of disc florets; bristles somewhat barbellate, in 1–3 series, at most somewhat dorsi-ventrally flattened and dissimilar in width near base, bases not to slightly overlapping, mostly 4–8 mm long. $n = 4$.

Although similar to *Machaeranthera* in several ways (see above), the members of *Dieteria* may be distinguished from it by foliage and fruit characters. *Dieteria* has entire to serrate or dentate leaves with thin-walled fruits that are mostly longer than 3 mm, while *Machaeranthera* has leaves that are deeply lobed or dissected and thick-walled fruits that are mostly 3 mm or less long. There is a great deal of morphological variation in *Dieteria*, which has resulted in a large number of species names. The treatment adopted here follows that of Turner (1987) in recognizing three species containing 16 varieties, with 3 varieties in *D. asteroides*, 3 in *D. bigelovii*, and 10 in *D. canescens*. Additional synonymy for *Dieteria* is included in Turner (1987).

KEY TO THE SPECIES OF *DIETERIA*

1. Phyllaries and peduncles both with prominent glandular pubescence.
   2. Leaves covered with stiff glandular hairs _____ **1. Dieteria asteroides** (var. **glandulosa**)
   2. Leaves glabrous to variously pubescent, but not covered with stiff glandular hairs.
      3. Midstem leaves linear-lanceolate to linear or linear-oblanceolate (ovate to obovate in var. *leucanthemifolia*), 1.5–5 mm wide; herbaceous phyllary apices acute to acuminate (1–3 mm long) _____ **3. Dieteria canescens**
      3. Differing from the above in at least one respect; midstem leaves lanceolate to oblanceolate and 5–15 mm wide, *or* herbaceous phyllary apices long-acuminate (2–6 mm long), *or* both _____ **2. Dieteria bigelovii**
1. Phyllaries and peduncles variously pubescent with glandular and/or nonglandular hairs, but rarely with prominent glandular pubescence on both.
   4. Phyllaries usually pubescent throughout, with pubescence on both herbaceous apices and indurate bases, apices acute to long-acuminate, 1–6 mm long; midstem leaves 6–20 mm wide (2–6 mm in var. *lagunensis*) _____ **1. Dieteria asteroides**
   4. Phyllaries only occasionally pubescent throughout, with pubescence mostly con-

fined to herbaceous apices, apices acute to acuminate, 1–3 mm long; mid-stem leaves 1.5–6(–8) mm wide _____ **3. Dieteria canescens**

1. Dieteria asteroides Torr., in Emory Report 142. 1848. *Machaeranthera asteroides* (Torr.) Greene, Pittonia 3:63. 1896. TYPE: U.S.A. NEW MEXICO: "elevated land between the Del Norte and the waters of the Gila," 16 Oct 1847, *Emory s.n.* (HOLOTYPE: NY).

Machaeranthera canescens var. *latifolia* A. Gray, Pl. Wright. 2:75. 1853. *Aster canescens* var. *latifolia* (A. Gray) A. Gray, Syn. Fl. N. Amer. 1(2):206. 1884. TYPE: U.S.A. New Mexico: "Near the copper mines," Sep–Oct 1851, *C. Wright 1152* (LECTOTYPE: GH [designated by Turner 1987]; ISOLECTOTYPES: GH, MO, NY, PH, UC, US).

Aster canescens Pursh var. *tephrodes* A. Gray, Proc. Amer. Acad. Arts 16:99. 1880. *Machaeranthera tephrodes* (A. Gray) Greene, Pittonia 4:24. 1899. *Aster tephrodes* (A. Gray) S.F. Blake, Contr. U.S. Natl. Herb. 25:563. 1925. Typification unclear: In Bot. Calif. 1:322. 1876, Gray mistakenly based the name *Aster incanus* (Lindl.) A. Gray on *Diplopappus incanus* Lindl. for plants occurring in southern California. He subsequently corrected this mistake and proposed the name *Aster canescens* var. *tephrodes* for these plants, noting that they also occurred in Arizona and New Mexico. Although stating that *A. c.* var. *tephrodes* "...was named *A. incanus* in the Botany of California, but....cannot be Lindley's plant," Gray apparently did not select a type specimen for *Aster canescens* var. *tephrodes*. The only material mentioned by Gray in connection with any of these names was collected by "Capt. E.K. Smith" in "Guadalupe Canyon, Sonora," but we have not been able to locate the specimens. Turner (1987) placed *Aster incanus*, *Aster canescens* var. *tephrodes*, *Machaeranthera tephrodes*, and *Aster tephrodes* in synonymy under *Machaeranthera canescens* var. *incana*.

KEY TO THE VARIETIES OF *DIETERIA ASTEROIDES*

1. Stems glabrous to glandular-pubescent; leaves covered with stiff glandular hairs _____ **1b. D. asteroides** var. **glandulosa**
1. Stems pubescent, puberulent, or canescent, glandular pubescence sparse or lacking; leaves puberulent or canescent, stiff glandular hairs sparse or lacking.
   2. Involucres hemispheric; herbaceous phyllary apices long-acuminate, 3 6 mm long; mid-stem leaves 6–20 mm wide, usually clearly serrate or serrulate _____ **1a. D. asteroides** var. **asteroides**
   2. Involucres broadly turbinate (rarely hemispheric); herbaceous phyllary apices acute to acuminate, 1–3 mm long; mid-stem leaves 2–6 mm wide, entire to slightly serrulate _____ **1c. D. asteroides** var. **lagunensis**

1a. Dieteria asteroides var. **asteroides**

1b. Dieteria asteroides var. **glandulosa** (B.L. Turner) D.R. Morgan & R.L. Hartman, comb. nov. BASIONYM: *Machaeranthera asteroides* (Torr.) Greene var. *glandulosa* B.L. Turner, Phytologia 60:77. 1986. TYPE: U.S.A. ARIZONA. Maricopa Co.: U.S. highway 60, 2.6 mi E of Queen Creek tunnel, 4200 ft, 19 Sep 1975, *Pinkava, Keil & Lehto L18904* (HOLOTYPE: LL!; ISOTYPES: ASU, CSU, NY).

San Diego Co.: 2 mi S of the main recreation area, Laguna Mountains, 5200 ft, 20 Aug 1952, *P.A. Munz & E.K. Balls 17948* (HOLOTYPE: NY; ISOTYPE: RSA).

2. Dieteria bigelovii (A. Gray) D.R. Morgan & R.L. Hartman, comb. **nov.** BASIONYM: *Aster bigelovii* A. Gray, Pacific Railway Survey 4:97. 1857. *Machaeranthera bigelovii* (A. Gray) Greene, Pittonia 3:63. 1896. TYPE: U.S.A. NEW MEXICO. Bernalillo Co.: "arroyos in the Sandia Mountains," 10 Oct 1853, *J.M. Bigelow s.n.* (HOLOTYPE: GH; ISOTYPE: NY).

KEY TO THE VARIETIES OF *DIETERIA BIGELOVII*

1. Involucres hemispheric, 2–3 times broad as tall; phyllaries 90–100, mostly 0.5–1 mm wide at midpoint, herbaceous apices long-acuminate, 2–5 mm long ____ **2c. D. bigelovii** var. **mucronata**

1. Involucres broadly turbinate to hemispheric, 1–2(–3) times broad as tall, phyllaries 25–100, mostly 1–2 mm wide at midpoint, herbaceous apices acute to long acuminate, 2–6 mm long.
   2. Phyllaries 25–50, apices acute to acuminate, 2–4 mm long; ray florets 12–30 ____ **2b. D. bigelovii** var. **commixta**
   2. Phyllaries 50–100, apices long-acuminate, 3–6 mm long; ray florets 30–60 ____ **2a. D. bigelovii** var. **bigelovii**

2a. Dieteria bigelovii var. **bigelovii**

2b. Dieteria bigelovii var. **commixta** (Greene) D.R. Morgan & R.L. Hartman, comb nov. BASIONYM: *Machaeranthera commixta* Greene, Pittonia 4:71. 1899. *Machaeranthera canescens* (Pursh) A. Gray var. *commixta* (Greene) S.L. Welsh, Great Basin Naturalist 43:316. 1983. *Machaeranthera bigelovii* (A. Gray) Greene var. *commixta* (Greene) B.L. Turner, Phytologia 60:77. 1986. TYPE: U.S.A. UTAH. Garfield Co.: Henry Mountains, Bromide Pass, 10,000 ft, 27 Jul 1894, *M.E. Jones 5695y* (HOLOTYPE: US; ISOTYPE: POM).

2c. Dieteria bigelovii var. **mucronata** (Greene) D.R. Morgan & R.L. Hartman, comb. nov. BASIONYM: *Machaeranthera mucronata* Greene, Pittonia 4:72. 1899. *Aster adenolepis* S.F. Blake, J. Wash. Acad. Sci. 30:471. 1940, nom. nov., non *Aster mucronatus* Sheldon, 1903. *Machaeranthera bigelovii* (A. Gray) Greene var. *mucronata* (Greene) B.L. Turner, Phytologia 62:238. 1987. TYPE: U.S.A. Arizona. Coconino Co.: Thompson Canyon, 8500 ft, 19 Sep 1894, *M.E. Jones 6065bl* (LECTOTYPE: US [designated by Turner 1987]).

3. Dieteria canescens (Pursh) Nutt., Trans. Amer. Philos. Soc., ser. 2, 7:300. 1840. BASIONYM: *Aster canescens* Pursh, Fl. Amer. Sept. 2:547, 1813. *Machaeranthera canescens* (Pursh) A. Gray, Pl. Wright. 1:89. 1852. TYPE: U.S.A. NORTH DAKOTA: "on the denuded banks of the Missouri" (vicinity of Fort Mandon), 1811, *Nuttall s.n.* (HOLOTYPE: BM; possible ISOTYPE: NDG).

Dieteria viscosa Nutt., Trans. Amer. Philos. Soc., ser. 2, 7:301. 1840. *Aster canescens* Pursh var. *viscosus* (Nutt.) A. Gray, Proc. Amer. Acad. Arts 16:99 1880. *Machaeranthera viscosa* (Nutt.) Greene, Pittonia 4:22. 1899. *Machaeranthera canescens* (Pursh) A. Gray var. *viscosa* (Nutt.) Piper, Contr. U.S. Natl. Herb. 11:576. 1905. TYPE: U.S.A. NEBRASKA. Scotts Bluff Co.: "near Scott's Bluff, on the Platte," 1834, *Nuttall s.n.* (HOLOTYPE: BM).

Dieteria divaricata Nutt., Trans. Amer. Philos. Soc., ser. 2, 7:301. 1840. *Machaeranthera divaricata* (Nutt.) Greene, Pittonia 4:23. 1899. TYPE: U.S.A.: "denudated plains of the Rocky Mountains and Oregon, common," 1834, *Nuttall s.n.* (HOLOTYPE: GH).

Dieteria pulverulenta Nutt., Trans. Amer. Philos. Soc, ser. 2, 7:300. 1840. *Machaeranthera*

pulverulenta (Nutt.) Greene, Pittonia 4:23. 1899. TYPE: U.S.A.: "arid plains towards the sources of the Platte," 1834, *Nuttall s.n.* (HOLOTYPE: PH).

Machaeranthera laetevirens Greene, Pittonia 3:61. 1896. *Aster leiodes* Blake, Contr. U.S. Natl. Herb. 25:563. 1925, nom. nov., non Aster *laetevirens* Greene (1900). TYPE: U.S.A. NEVADA. Elko Co.: Clover Mountains, 26 Jul 1894, *E.L. Greene s.n.* (HOLOTYPE: NDG; ISOTYPE: NDG).

Machaeranthera latifolia A. Nelson, Proc. Biol. Soc. Wash. 20:38. 1907. *Machaeranthera canescens* (Pursh) A. Gray var. *latifolia* (A. Nelson) S.L. Welsh, Great Basin Naturalist Mem. 9:213. 1987. *Machaeranthera canescens* (Pursh) A. Gray var. *monticola* Dorn, Vascular Pl. Wyo. 295. 1988. TYPE: U S.A. UTAH. Salt Lake Co.: Big Cottonwood Canyon, 8950 ft, 9 Aug 1933, *A. O. Garrett 1933* (HOLOTYPE: RM!; ISOTYPES: GH, LL!, US).

KEY TO THE VARIETIES OF *DIETERIA CANESCENS*

1. Phyllaries spreading to reflexed, rarely appressed.
   2. Involucres mostly (9–)10–16 mm tall.
      3. Suffruticose perennials; involucres (10–)12 -16 mm tall; phyllary apices densely glandular _____ **3f. D. canescens** var. **ziegleri**
      3. Biennials or short-lived perennials; involucres (9)10–15 mm tall; phyllary apices densely appressed-pubescent, glands if present obscured by appressed pubescence _____ **3j. D. canescens** var. **nebraskana**
   2. Involucres mostly 6–10(–12) mm tall.
      4. Stems canescent; glandular pubescence sparse or lacking.
         5. Plants usually with a single stiffly erect stem; branches stiff and straight, widely divaricate _____ **3b. D. canescens** var. **incana**
         5. Plants with a single stem or with multiple ascending stems; branches flexible and curved, loosely spreading or (usually) ascending but not widely divaricate.
            6. Ray florets sterile or absent; phyllaries 3–5(–7) seriate _____ **3e. D. canescens** var. **shastensis**
            6. Ray florets pistillate and fertile; phyllaries 5–10 seriate _____ **3a. D. canescens** var. **canescens**
      4. Stems evidently glandular, frequently also puberulent or canescent, occasionally glabrous.
         7. Stems canescent, glands usually sessile or subsessile; most heads sessile or with peduncles shorter than involucre height _____ **3d. D. canescens** var. **sessiliflora**
         7. Stems with prominent stipitate glands, also occasionally puberulent or canescent; most peduncles longer than involucre height.
            8. Midstem and upper leaves ovate, oblong or obovate, 1.5–4 times longer than wide _____ **3c. D. canescens** var. **leucanthemifolia**
            8. Midstem and upper leaves linear-lanceolate to linear, more than 4 times longer than wide _____ **3h. D. canescens** var. **aristata**
1. Phyllaries appressed or occasionally spreading, rarely reflexed.
   9. Ray florets sterile or absent _____ **3e. D. canescens** var. **shastensis**
   9. Ray florets pistillate and fertile.
      10. Phyllaries densely appressed pubescent, glandular pubescence lacking or sparse and obscured by appressed pubescence _____ **3g. D. canescens** var. **ambigua**
      10. Phyllaries glabrous to glandular-pubescent, rarely appressed-pubescent or canescent.
         11. Stems with prominent stipitate glands, occasionally also canescent, rarely glabrous _____ **3h D. canescens** var. **aristata**

11. Stems glabrous to puberulent or canescent, stipitate glands sparse or lacking _____ **3i D. canescens** var. **glabra**

(i) Dieteria canescens subsp. **canescens**

3a. Dieteria canescens var. **canescens**

3b. Dieteria canescens var. **incana** (Lindl.) D.R. Morgan & R.L. Hartman, comb. nov. BASIONYM: *Diplopappus incanus* Lindl., Bot. Reg. 20:t. 1693, 1834. *Dieteria incana* (Lindl.) Torr. & A. Xanthisma DC., Prodr. 5:94. 1836. TYPE: *Xanthisma texanum* DC.

Eriocarpum Nutt., Trans. Amer. Philos. Soc., ser. 2, 7:320. 1840. TYPE: *Eriocarpum grindelioides* Nutt.

Sideranthus Nutt. ex C. Nees in M. Wied-Neuwied, Reise Nord-America 2:440. 1841. TYPE: *Amellus spinulosus* Pursh.

Centauridium Torr. & A. Gray, Fl. N. Amer. 2:246. 1842. TYPE: *Centauridium drummondii* Torr. & A. Gray.

Dieteria subgenus *Sideranthus* (Nutt. ex Nees) Nutt., Trans. Amer. Philos. Soc., ser. 2, 7:301. 1840.

Machaeranthera subgenus *Sideranthus* (Nutt. ex Nees) R.L. Hartman, Phytologia 68:456. 1990.

There has been disagreement on the dates of publication for *Eriocarpum* and *Sideranthus*. For example, Farr, Leussink, and Stafleu (1979) give them as Oct–Dec 1840 and 1840, respectively. According to Greene (1895), Nuttall's treatment (p.320) of *Eriocarpum* appeared in 1840 (for pp. 283–356). Subsequently, *Sideranthus* was published by C. Nees in 1841 (Stafleu & Cowan 1981, p. 707).

Herbs taprooted annuals, biennials, or perennials, if perennial usually with a much-branched, woody caudex or rhizomatous (forming loose colonies in *X. rhizomatum*), 3–100 cm tall. **Stems** erect or spreading or sprawling, often much branched, glabrous or moderately to densely pubescent with glandular or nonglandular hairs. **Leaves** alternate; entire to serrate, dentate, pinnatifid, or

bipinnatifid, moderately to densely pubescent with glandular or nonglandular hairs, apices, including lobes and teeth, apiculate to bristle tipped, bristles if present 1–4 mm long. **Heads** radiate or eradiate. **Involucres** turbinate, campanulate, or hemispheric. **Phyllaries** in 2–8 imbricate series, graduated in length, appressed, spreading, or reflexed, glabrous or moderately to densely pubescent with glandular or nonglandular hairs; bases indurate, apices herbaceous or achlorophyllous, stiff, leathery, or margins scarious. **Receptacles** alveolate, flat to convex, scales laciniate, 0.3–3 mm long, often forming a reticulum. **Ray florets** pistillate, fertile (absent in *X. grindelioides, X. johnstonii, X. restiforme*); corollas white, pink, red-purple, purple, or yellow. **Disc florets** bisexual, fertile, corollas yellow, ± funnelform, tubes and limbs glabrous to somewhat pubescent, lobes 0.4–0.9 mm long, glabrous to pubescent. **Cypselae** of ray and disc florets distinctly dimorphic, elliptic to obovate, oblong, or obscurely cordate, sparsely to densely pubescent; thin to thick walled, with 3–9 nerves or ribs per face, (1–)1.5–3.5 mm long, those of ray florets, if present, ± 3 sided, rounded abaxially, of disc florets compressed laterally; pappus usually whitish to brown or reddish brown, of ray florets 1/2 to nearly equaling length of disc florets; bristles coarsely barbellate, in 2–4 series, dorsi-ventrally flattened and dissimilar in width near base, bases overlapping, mostly 3.5–8 mm long. $n = 2, 3, 4, 8$.

As defined here, the genus *Xanthisma* consists of the former *Machaeranthera* sections *Blepharodon*, *Sideranthus*, *Havardii*, and *Stenoloba*, plus the unispecific genus *Xanthisma*, which because of the rule of priority becomes the name of the genus. The grouping of *Xanthisma* and these four sections of *Machaeranthera* (sensu Morgan 1993) was well supported by nrDNA evidence (Morgan 2003), and, except for *Arida blepharophylla* (see discussion below), cpDNA evidence did not support any conflicting relationships (Fig. 1). Although *Xanthisma* includes species with both cyanic (blue, purple, pink, or white) and yellow rays, several other morphological characteristics are shared by its members, including short, turbinate, thick-walled fruits that are densely pubescent, receptacular scales, leaves with marginal spines, and chromosome numbers based on $x = 4$. Many of these species have in fact been grouped together at the generic or sectional level by authors such as Greene (1894) and Hall (1928).

The following key is based largely on data from Hartman (1976, 1990) and Semple (1974).

KEY TO THE SPECIES OF *XANTHISMA*

1. Inner phyllaries, at least, with a basal "stalk," abruptly enlarged into an ovate to orbicular or elliptic blade, mostly 2–5 mm wide and glabrous; apices abruptly acuminate to obtuse, or broadly rounded, not bristle-tipped _____ **1. Xanthisma texanum**
1. Inner phyllaries, as with all, not markedly expanded above, linear to broadly oblong or lanceolate, mostly 1 -2 mm wide; apices narrowly obtuse to long-attenuate, usually bristle-tipped.

2. Ray florets absent.
   3. Primary cauline leaves mostly 1–6 cm long, if shorter or absent then plants with several single headed stems arising from a cushion of basal leaves; stems lacking axillary rosettes; NW New Mexico and N Arizona to S Canada _____ **5. Xanthisma grindelioides**
   3. Primary cauline leaves 0.2–1 cm long, basal leaves not persisting on mature plants; stems covered by axillary rosettes of tiny leaves; Coahuila and Nuevo León, Mexico.
      4. Main stem leaves on new growth oblong to narrowly lanceolate; stems canescent to slightly tomentose, the pubescence increasing the stem diameter but slightly; plants much branched and bushy with flexible stems _____ **8. Xanthisma johnstonii**
      4. Main stem leaves deltoid to narrowly triangular; stems densely woolly-tomentose, the pubescence increasing the stem diameter 2 to 3 times; plants divergently but sparingly branched with rigid, rope like stems _____ **9. Xanthisma restiforme**
2. Ray florets present.
   5. Ray floret corollas white, pink, purple, or lavender.
      6. Plants dwarf, arising from a cluster of basal leaves; stems leafy, up to 12 cm tall, few to several, each 1 headed; montane to alpine, Colorado and S Wyoming _____ **3. Xanthisma coloradoense**
      6. Plants usually robust, basal leaves usually not persisting on the mature plant; stems not always leafy, mostly 15 to 40 cm tall, often branched, each with 1 to 10 or more heads; central NM, W Texas; N half of Mexico.
         7. Plants biennial or short-lived perennial herbs from a normal taproot; ray flowers pink, purple, or lavender (often fading on old specimens); peduncles moderately to densely glandular-stipitate, often with long flexuous hairs intermixed; phyllaries usually herbaceous in upper half, long-attenuate, reflexed or widely spreading; highlands, central Mexico to S edge of the Chihuanuan Desert _____ **6. Xanthisma gymnocephalum**
         7. Plants perennial from a woody, branched caudex, often with a thickened taproot; ray flowers white (rarely purple in *X. gypsophilum*), often with pink or purple streaks on the underside; peduncles villous, hispid, or glandular-stipitate; phyllaries not herbaceous above but with a green or purple strip or patch in the upper half, the tips acute to broadly acuminate, appressed to squarrose; Chihuahuan Desert and vicinity and mountains of W Texas and S New Mexico.
            8. Peduncles and leaves moderately to densely villous; leaves crowded on the lower half to two-thirds of the stem, not greatly reduced in size above (except for 1 or 2 reduced bracts); flowering stems usually unbranched, bearing only one head _____ **4. Xanthisma crutchfieldii**
            8. Peduncles and leaves glandular-stipitate and/or hispid to hispidulose; leaves evenly distributed along the stem usually for well over two-thirds its length, often markedly though gradually reduced in size above; flowering stems often at least sparingly branched with 1 to 10 or more heads.
               9. Peduncles stipitate-glandular; leaves serrate, often coarsely so with 5 to 14 pairs of teeth; SE New Mexico, W Texas; N Mexico _____ **7. Xanthisma gypsophilum**
               9. Peduncles hispid or hispidulose; leaves usually finely or obscurely

serrate or serrulate, usually with 12 to 25 pairs of teeth; south-central New Mexico to W Texas _____ **2. Xanthisma blephariphyllum**

5. Ray floret corollas yellow.
   10. Plants growing in loose colonies with stems arising from 3 to 10 or more elongate (2–15 cm or more long), branched rhizomes, 1.5–6 mm in diameter, arising from a woody rootstock; leaves without glands _____ **10. Xanthisma rhizomatum**
   10. Plants from a taproot or woody caudex, not rhizomatous; leaves often glandular.
      11. Cypselae of disc florets broadly obovate to obscurely and narrowly cordate, the thick, bony walls with 10–12 prominent ribs, densely pubescent, margins thickened; pappus mostly of subulate, markedly dorsiventrally flattened bristles 2–3 mm long; plants annual; leaves deeply pinnatifid or bipinnatifid; SW Chihuahua, Mexico _____ **15. Xanthisma stenolobum**
      11. Cypselae of disc florets oblong to narrowly obovate, walls usually thin, flexible, smooth or with 6–16 obscure ribs, glabrous to moderately pubescent, margins not thickened; pappus of filiform, only slightly flattened bristles 3.5–7 mm long; plants annual to perennial; leaves entire to bipinnatifid; occurring elsewhere.
         12. Plants taprooted, annual; phyllaries obtuse to broadly acute, not bristle tipped; leaves serrate or dentate, the teeth blunt or terminating in a stiff callosity, not bristle tipped; cypselae oblong or narrowly elliptic with 12–14 barely discernible nerves, sparsely pubescent; lowlands of SE New Mexico and W Texas _____ **17. Xanthisma viscidum**
         12. Plants perennial with much-branched caudices, if taprooted annuals then phyllaries with narrowly acute to acuminate and prominently bristle tipped apices; leaves various, if serrate or dentate, the teeth bristle tipped; cypselae elliptic to narrowly obovate with 6–16 weak ribs, glabrous to moderately pubescent; Canada to S U.S.; Mexico.
            13. Plants annual with herbaceous stems and bases; involucres eglandular.
               14. Leaves with entire margins, not bristle lined, or lower cauline and basal ones tridentate or sometimes pinnatifid; phyllaries tipped by bristles 0.1–0.3 mm long; NE Baja California, Mexico _____ **16. Xanthisma wigginsii**
               14. Leaves uniformly spinulose toothed or lobed, bristles usually 1.5 3 mm long; phyllaries (except innermost series) tipped by bristles usually 0.6–1.5 mm long; occurring elsewhere _____ **12. Xanthisma gracile**
            13. Plants perennial, stems with woody bases; involucres glandular.
               15. Bracts of peduncles imbricate and grading into phyllaries; stems nearly leafless above base _____ **13. Xanthisma junceum**
               15. Bracts of peduncles few and not grading into phyllaries; stems leafy or leaves reduced near inflorescence.
                  16. Phyllaries strongly squarrose in upper half; leaves thickish, usually oblanceolate to spatulate with

bluntly dentate to subentire margins; S Baja California Sur, Mexico _____ **11. Xanthisma arenarium**

16. Phyllaries with appressed to spreading apices; leaves thin, usually oblong to lanceolate with prominent teeth or lobes; SW Canada, W U.S.A.; N half of Mexico _____ **14. Xanthisma spinulosum**

Xanthisma DC. section **Xanthisma**

Herbs taprooted annuals, rarely biennials, 20–90 cm tall, taproot sometimes thickened. **Leaves** entire on upper stem, serrate below, pinnatifid to bipinnatifid near base, teeth or lobes usually with apiculate callosities, not bristle tipped. **Heads** radiate. **Involucres** turbinate to hemispheric or campanulate. **Phyllaries** in 3–4 graduated series, the lower portion stalk-like, stiff, stramineous, enlarged above into an ovate to orbicular or depressed elliptic blade with a glabrous, green patch; apices acuminate or obtuse and cuspidate or broadly rounded, not bristle tipped. **Receptacles** alveolate, scales 0.2–2 mm long, mostly distinct. **Ray floret** corollas yellow. **Cypselae** distinctly dimorphic, 1.5–2.2 mm long, narrowly obovoid to oblong, walls thick with 8–16, often obscure ribs, sparsely pubescent; ray cypselae 3 sided; disc cypselae compressed laterally, generally 4 sided. **Pappus** similar in ray and disc florets, tawny; bristles 3–7 mm long, linear, dorsiventrally flattened basally, in 2 series. $n = 4$.

1. Xanthisma texanum DC., Prodr. 5:95. 1836. TYPE: U.S.A. TEXAS. Bexar Co.: woods near Medina, May 1828. *J.L. Berlandier 2039* (LECTOTYPE: IDC microfiche 800. 787.I.7, G-DC! [designated by Semple 1974]; ISOLECTOTYPES: G-DC, GH, NY, US).

Xanthisma texanum DC. var. *berlandieri* A. Gray, Pl. Wright. 1:98. 1852. *Xanthisma berlandieri* (A. Gray) J.K. Small, Fl. S.E. U.S. 1184. 1903. TYPE: U.S.A. SOUTHERN TEXAS: *J.L. Berlandier s.n.*; on the Nueces, *A. Trécul s.n.* (SYNTYPES: GH).

KEY TO THE INFRASPECIFIC TAXA OF *XANTHISMA TEXANUM*

1. Blades of phyllaries somewhat expanded above the proximal stalk, mostly orbicular to depressed elliptic: dimensions above the widest part 1–2 mm long, 1.5–3.5 mm wide _____ **1a. X. texanum** subsp. **texanum**

2. Phyllary apices rounded with little or no flare 1 mm from the apex _____ **1b. X. texanum** subsp. **texanum** var. **texanum**

2. Phyllary apices obtusely cuspitate, flared distally, the ovate portion 1.5–2 mm long, 2–3 mm wide above the widest portion _____ **1c. X. texanum** subsp. **texanum** var. **orientale**

1. Blades of phyllaries abruptly expanded above proximal stalk, mostly ovate: dimensions above the widest part 3.5–8 mm long, 2.5–5 mm wide _____ **1d. X. texanum** subsp. **drummondii**

1a. Xanthisma texanum DC. subsp. **texanum**

1b. Xanthisma texanum DC. subsp. **texanum** var. **texanum**

1c. Xanthisma texanum DC. subsp. **texanum** var. **orientale** Semple, Rhodora 76:14.

1974. TYPE: U.S.A. TEXAS. Hidalgo Co.: 13.5 mi N of Edinburg on U.S. hwy 183, 8 Jul 1970, *W. Lewis 7642* (HOLOTYPE: MO).

1d. Xanthisma texanum DC. subsp. **drummondii** (Torr. & A. Gray) Semple, Rhodora 76:16. 1974. BASIONYM: *Centauridium drummondii* Torr. & A. Gray, Fl. N. Amer. 2:246. 1842. *Xanthisma texanum* DC. var. *drummondii* (Torr. & A. Gray) A. Gray, Pl. Wright. 1:98. 1852. *Xanthisma drummondii* (Torr. & A. Gray) Hooker f., Curtis' Bot. Mag. 33:t. 6275. 1877. TYPE: U.S.A. TEXAS: exact locality unknown, Nov 1835, *T. Drummond 227* (LECTOTYPE: GH [designated by Semple 1974]; ISOLECTOTYPES: GH!, NY!).

Xanthisma texanum DC. subsp. *texanum* var. *orientale* Semple forma *rubrum* Semple, Rhodora 76:15. 1974. TYPE: U.S.A. TEXAS. San Patricio Co.: 0.5 mi E of Ingleside on Texas hwy 361, 13 Jun 1971, *J.C. Semple 602* (HOLOTYPE: MO).

This polymorphic species has always been maintained distinct from other genera in the Tribe; in part due to the unique involucre. The relationship to members of *Machaeranthers* sensu lato was never seriously considered until data from DNA became available. According to Semple (1974) the following combination of features characterized the species: "heterocarpic fruit with a pappus of bristly scales only, fruit pubescence of long white ascending hairs, receptacle slightly convex with a persistent reticulate network of subulate scales." Interestingly, all of these characters are found in at least some of the taxa of this newly expanded genus.

Semple (1974) recognized two forms of variety *orientale*, the typical one having whitish lateral margins on the bracts and forma *rubrum* in which the lateral margins were red. Forma *rubrum* is said to be rare but is found mixed with the typical form throughout the range of var. *orientale*.

Xanthisma section **Blepharodon** (DC.) D.R. Morgan & R.L. Hartman, comb. nov. BASIONYM: *Haplopappus* section *Blepharodon* DC., Prodr. 5:346. 1836, "*Aplopappus*," non *Blepharodon* Decne. in DC., 1844 [Asclepiadaceae].

Machaeranthera section *Blepharodon* (DC.) R.L. Hartman, Phytologia 68:443. 1990. TYPE: *Haplopappus gymnocephalus* DC., "*Aplopappus*" (lectotype designated by Hall 1928, from among the four species included).

Eriocarpum Nutt., Trans. Amer. Philos. Soc., ser. 2, 7:320. 1840. *Haplopappus* section *Eriocarpaea* Benth. & J.D. Hook., Gen. Pl. 2:254. 1873, based on *Eriocarpum* Nutt., Trans. Amer. Philos. Soc., ser. 2, 7:320. 1840. TYPE: *Eriocarpum grindelioides* Nutt.

Machaeranthera series *Originales* Cronquist & D.D. Keck, Brittonia 9:237. 1957, nom. illeg. (ICBN: 24.3).

Herbs taprooted annuals, biennials, or perennials, 3–50 cm tall, often with a much branched caudex or in loose colonies with stems arising from 3 to 10 or more elongate, branched rhizomes, 1.5–6 mm in diameter, from a woody rootstock. **Leaves** serrate or dentate, entire or rarely pinnatifid in a few species, teeth or lobes usually bristle tipped. **Heads** radiate or eradiate. **Involucres** depressed hemispheric to campanulate. **Phyllaries** in 3–6 graduated series, linear to lanceolate, the lower portion thickened, stramineous, the upper fourth to half her-

baceous or with a green or purple tinged strip or patch, stipitate glandular to canescent, appressed to reflexed; apices obtuse to long attenuate and usually bristly tipped. **Receptacles** alveolate, scales often present, 0.3–1.5 mm long, distinct or forming a reticulum. **Ray floret** corollas white, pink, purple, or lavender when present (yellow in *Xanthisma rhizomatum*). **Cypselae** distinctly dimorphic, (1–)1.5–3.5 mm long, narrowly obovoid to oblong, the walls thick with 6–18, often prominent ribs, often densely pubescent; ray cypselae obscurely 3 sided; disc cypselae compressed laterally. **Pappus** white to tawny; bristles 3.5–8 mm long, dorsiventrally flattened basally, in 2–4 graduated series, those of the ray florets often much reduced in length. $n = 4, 8$.

2. Xanthisma blephariphyllum (A. Gray) D.R. Morgan & R.L. Hartman, comb. nov. BASIONYM: *Haplopappus blephariphyllus* A. Gray, Pl. Wright. 1:97. 1852, "*Aplopappus*." *Eriocarpum blephariphyllum* (A. Gray) Greene, Erythea 3:14. 1895. *Machaeranthera blephariphylla* (A. Gray) Shinners, Field & Lab. 18:38. 1950. TYPE: U.S.A. Probably TEXAS: plains at the eastern base of the Guadalupe Mountains, 18 Oct 1849, *C. Wright 288* (HOLOTYPE: GH!; ISOTYPE: NY!).

Eriocarpum serratum Greene, Bull. Torrey Bot. Club 25:119, pl. 331, fig. 3, 4. 1898. *Sideranthus serratus* (Greene) Standley, Contr. U.S. Natl. Herb. 13:222. 1910. TYPE: U.S.A. NEW MEXICO. Lincoln Co.: White Mountains, S fork of Tularosa Creek E of the Mescalero Agency, 6800 ft, 30 Jul 1897, *E.O. Wooton 251* (HOLOTYPE: NDG!; ISOTYPES: B, K, MO!, NY!, RM!, UC!).

Machaeranthera correllii Shinners, Field & Lab. 17:55. 1949. TYPE: U.S.A. TEXAS. Culberson Co.: Guadalupe Mountains, Pine Springs Canyon, 5700 ft, 15 Aug 1946, *L. Shinners 9059* (HOLOTYPE: SMU!).

3. Xanthisma coloradoense (A. Gray) D.R. Morgan & R.L. Hartman, comb. nov. BASIONYM: *Aster coloradoensis* A. Gray, Proc. Amer. Acad. Arts 11:76. 1876. *Eriocarpum coloradoense* (A. Gray) Greene, Erythea 2:110. 1894, "*coloradense*." *Xylorhiza coloradoensis* (A. Gray) Rydb., Bull. Torrey Bot. Club 32:124. 1905, "*Xylorrhiza coloradensis*." *Machaeranthera coloradoensis* (A. Gray) Osterhout, Torreya 27:64. 1927, "*coloradensis*," *Haplopappus coloradoensis* (A. Gray) R.L. Hartman ex R. D. Dorn, Vasc. Pl. Wyoming 295. 1988. TYPE: U.S.A. Haplopappus texensis R.C. Jackson, Rhodora 64:142. 1962. *Machaeranthera texensis* (R.C. Jackson) Shinners, Sida 1:378. 1964. TYPE: U.S.A. TEXAS. Brooks Co.: sandy soil along railroad right-of way about 7.5 mi S of Falfurrias, 7 Aug 1959, *R.C. Jackson 2938-1* (HOLOTYPE: KANU!).

The following two binomials are not valid as the genus *Sideranthus* was a nomen nudum when the combinations were published: *Sideranthus pinnatifidus* Nutt., Fraser's Catalogue, no. 81, 1813, non *Aplopappus pinnatifidus* Nutt., 1840 and *Sideranthus spinulosus* (Pursh) Sweet, Hort. Brit., 227. 1826. Furthermore, *Eriocarpum australe* Greene (Erythea 2:108. 1894) although validly published has never been lectotypfied. The relevant synonyms are: *Sideranthus australis* (Greene) Rydb., Bull. Torrey Bot. Club 27:621. 1900; *Haplopappus spinulosus* (Pursh) DC. subsp. *australis* (Greene) H.M. Hall, Publ. Carnegie Inst. Wash. 389:77. 1928; and *Machaeranthera australis* (Greene) Shinners, Field & Lab. 18:42. 1950.

Xanthisma spinulosum "is an exceedingly complex, variable taxon. It is doubtful that any 'absolute' key can be constructed so as to recognize unequivocally the infraspecific categories proposed here. Instead, we have composed a key that attempts to recognize character *trends*, in combination, that serve to distinguish a given taxon from another, but the occasional (if not frequent) specimen will be found that keys to a given regional variety but belongs to yet another. However, if one accepts the exception and recognizes our account as an attempt to portray quite variable, *regional populations* and not as a key to individuals, then little trouble would be experienced in pinning a varietal name on this or that collection" (Turner & Hartman 1976). The following key is adapted from the aforementioned source.

KEY TO THE VARIETIES OF *XANTHISMA SPINULOSUM*

1. Involucres of pressed heads 15–25 mm wide, heads mostly sol'tary on elongate peduncles 2–15 cm or more long (shorter in Baja California, Mexico); herbs and subshrubs mostly (30–)50–100 cm tall; foliage relatively sparse, crowded below, internodes at mid-stem 0.5–2 mm or more long (short in Baja California, Mexico); W Colorado to S California and Arizona; Baja California, Mexico and vicinity.
2. Heads borne on elongate, leafy "peduncles," tne upper leaves not mucn reduced, subspinose; subshrubs up to 100 cm tall _____ **14d. X. spinulosum** var. **gooddingii**
2. Heads borne on relatively short, leafy "peduncles," the upper leaves not much reduced nor subspinose; perennial herbs, but often woody below or at the crown, mostly 30–60 cm tall.
3. Heads broadly campanulate; lower leaves generally 2–3 cm long, pinnatisect; W Colorado, adjacent Utah, New Mexico, and Arizona _____ **14f. X. spinulosum** var. **paradoxum**

3. Heads broadly turbinate to campanulate; lower leaves 0.5–2 cm long, dentate to nearly incised leaves; Baja California, Mexico.
   4. Involucres of pressed heads 22–25 mm wide; leaves large, decidedly incised; coastal islands _____ **14e. X. spinulosum** var. **incisifolium**
   4. Involucres of pressed heads 15–20 mm wide; leaves small and nearly serrate or dentate; widespread on mainland _____ **14g. X. spinulosum** var. **scabrellum**

1. Involucre of pressed heads 8–15 mm wide, heads mostly 2 to 10 or more per stem on relatively terminal and lateral peduncles 0.5–2 cm long; herbs mostly 20–50 cm tall; foliage abundant and not much reduced upwards, internodes at mid-stem 0.2–0.5 cm or less long.
   5. Stems stiffly erect, mostly unbranched, foliage glabrate or nearly so; heads nearly sessile; pappus bristles profuse, exceeding the disc corollas; South Dakota to N Texas _____ **14c. X. spinulosum** var. **glaberrimum**
   5. Stems spreading to sprawling, usually much-branched, foliage variously pubescent, rarely glabrous; pappus less pronounced in the head, equaling the disc corolla; widespread, W Canada to SW U.S.A.; central Mexico.
      6. Involucres of pressed heads 8–12 mm wide; stems equally leafy throughout; plants only rarely stiffly erect or woody at the base, mostly 10–40 cm tall; widespread _____ **14a. X. spinulosum** var. **spinulosum**
      6. Involucres of pressed heads 12–16 mm wide; stems mostly leafy below, upper leaves much reduced giving the heads a "long-peduncled" appearance; plants stiffly erect and often woody at the base, mostly 30–50 cm tall; W Texas, S New Mexico, S Arizona; N Mexico _____ **14b. X. spinulosum** var. **chihuahuanum**

(i) Xanthisma spinulosum subsp. **spinulosum**

BASIONYM: *Haplopappus wigginsii* S.F. Blake, Proc. Biol. Soc. Wash. 48:169. 1935, "*Aplopappus.*" *Machaeranthera wigginsii* (S.F. Blake) R.L. Hartman, Phytologia 68:458. 1990. TYPE: MEXICO. BAJA CALIFORNIA: Sierra San Pedro Mártir, 18 Sep 1930, *I. L. Wiggins & D. Demaree 4914* (HOLOTYPE: US!).

Xanthisma section **Havardii** (R.C. Jackson) D.R. Morgan & R.L. Hartman, comb. nov. BASIONYM: *Haplopappus* section *Havardii* R.C. Jackson, Univ. Kansas Sci. Bull. 46:479. 1966. *Machaeranthera* section *Havardii* (R.C. Jackson) R.L. Hartman, Phytologia 68:458. 1990.

Herbs taprooted annuals, 15–45 cm tall. **Leaves** serrate or dentate, often coarsely so, teeth blunt or terminating in stiff callosities, not bristle-tipped. **Heads** radiate. **Involucres** broadly turbinate. **Phyllaries** in 5–7 graduated series, linear to narrowly oblong, the lower portion rigid, stramineous, the upper fifth to half with a green patch or strip, densely glandular, appressed; apices obtuse to acute. **Receptacles** alveolate, scales 0.1–0.5 mm long, mostly distinct. **Ray floret** corollas yellow. **Cypselae** essentially similar, 2.5–3 mm long, oblong or narrowly elliptic, sometimes slightly asymmetrical, flattened laterally, walls thin with 12–14 barely discernible nerves, sparsely pubescent. **Pappus** similar in ray and disc florets, white; bristles 5–7 mm long, filiform, not dorsiventrally flattened basally, in 2–3 poorly defined series. $n = 4$.

17. Xanthisma viscidum (Wooton & Standley) D.R. Morgan & R.L. Hartman, comb. nov. BASIONYM: *Sideranthus viscidus* Wooton & Standley, Contr. U.S. Natl. Herb. 16:180. 1913. *Haplopappus viscidus* (Wooton & Standley) S.F. Blake, J. Wash. Acad. Sci. 28:486. 1938. *Machaeranthera viscida* (Wooton & Standley) R.L. Hartman, Phytologia 68:459. 1990. TYPE: U.S.A. NEW MEXICO. Eddy Co.: near Hope, 3 Aug 1905, *E.O. Wooton s.n.* (HOLOTYPE: US!).

Haplopappus havardii Waterfall, Rhodora 45:352. 1943. *Machaeranthera havardii* (Waterfall) Shinners, Field & Lab. 18:40. 1950. TYPE: U.S.A. TEXAS. Culberson Co.: 9 mi E of Van Horn, s.d., *U.T. Waterfall 4153* (HOLOTYPE: GH!; ISOTYPES: ARIZ!, MO!, NY!).

Arida D.R. Morgan & R.L. Hartman, comb. et stat. nov. BASIONYM: *Machaeranthera* section *Arida* R.L. Hartman, Phytologia 68:446. 1990. TYPE: *Machaeranthera arida* B.L. Turner & D.B. Horne.

Herbs taprooted annuals or rarely short lived perennials (often much branched, rhizomatous, forming vegetative rosettes in *A. blepharophylla*), 10–60(–80) cm tall. **Stems** erect to ascending or sprawling, often much branched, glabrous to variously pubescent with glandular and nonglandular hairs. **Leaves** alternate; entire, dentate, lacerate to deeply pinnatifid or bipinnatifid, glabrous to densely pubescent with glandular or nonglandular hairs, apices, including lobes and teeth, apiculate to bristle tipped, bristles 0.1–1 mm long. **Heads** radiate or eradiate. **Involucres** turbinate to depressed hemispheric. **Phyllaries** in 4–8 imbricate series, graduated in length, appressed, spreading, or reflexed, glabrous or moderately to densely pubescent with glandular or nonglandular hairs; bases indurate to herbaceous, apices herbaceous, margins sometimes scarious.

Receptacles indistinctly alveolate, convex, naked or nearly so, or (in *A. blepharophylla*) with scales up to 0.5 mm long. **Ray florets** pistillate, fertile (absent in *A. carnosa*); corollas light to dark blue. **Disc florets** bisexual, fertile, corollas yellow, ± funnelform, tubes and limbs generally glabrous, lobes 0.3–0.5 mm long, glabrous to minutely pubescent. **Cypselae** of ray and disc florets somewhat dimorphic, narrowly oblong, moderately to densely pubescent; thin walled, with 5–11 filiform nerves per face, 1–3.2(–4) mm long, those of ray florets, if present, obscurely 3 sided, rounded abaxially, of disc florets only slightly compressed laterally; pappus white or whitish (tawny in *A. blepharophylla*), of ray florets 1/3 to nearly equaling length of disc florets; bristles minutely barbellate, in 2–3 poorly differentiated series, at most somewhat dorsi-ventrally flattened and dissimilar in width near base, bases not to slightly overlapping, mostly 2.5–4.5(–5) mm long. $n = 5$.

Four of the nine species that are here included in *Arida* (*A. blepharophylla*, *A. parviflora*, *A. riparia*, and *A. turneri*) were included in molecular investigations of *Machaeranthera* s.l. (Morgan & Simpson 1992; Morgan 1997, 2003). The conflicting relationships supported by cpDNA and nrDNA for these species suggested substantial reticulate evolution among the four species and with species of *Dieteria*, *Pyrrocoma*, and *Xanthisma*, complicating efforts to produce a taxonomy that best reflects current understanding of the systematics of *Arida*.

In classifying the species of *Arida*, one issue to consider is the proper taxonomy for *A. blepharophylla*. Chloroplast DNA and nrDNA supported conflicting relationships for this species (Fig. 1), suggesting that it has experienced reticulate evolution (Morgan 1997, 2003). Since the taxonomy of *A. blepharophylla* should match its evolutionary history as closely as possible, it would be desirable to base its classification on what kind of reticulate evolution has occurred. As described by Morgan (1997), there are two major possibilities. First, because *A. blepharophylla* exhibits characteristics of both parental lineages, it could have originated through hybrid speciation; the best treatment in this situation might be to establish *A. blepharophylla* as a monospecific genus descended from, but separate from, both parental lineages.

The second evolutionary possibility is that *A. blepharophylla* is a close relative of *A. riparia* that has acquired chloroplast DNA from the ancestor of *Xanthisma gymnocephalum*; the best treatment in this case might be to classify it with *A. riparia*. Here we choose the latter disposition. According to nrDNA evidence, the nuclear relationships of *A. blepharophylla* are with *A. riparia*. In addition, the majority of its characteristics, including chromosome number and fruit morphology, are shared with *A. riparia* rather than with *X. gymnocephalum* (Nesom et al. 1990). It is possible that *Arida blepharophylla* is a hybrid species, but in our view additional genetic data would be necessary to convincingly demonstrate the occurrence of hybrid speciation. In the absence of such data we propose that *A. blepharophylla* be considered a close relative of

A. riparia that has experienced chloroplast introgression, and that its taxonomy reflect this history.

With *Arida blepharophylla* classified with *A. riparia*, the next question is whether the nine species of *Arida* should all be maintained in the same genus. If *A. blepharophylla* is placed with *A. riparia* as described above, cpDNA evidence would support keeping all the species together because it supported a group composed of *A. parviflora*, *A. turneri*, and *A. riparia* (Fig. 1). However, nrDNA evidence separated these four species into two lineages (Fig. 1). As described in detail by Morgan (2003), there are two primary explanations for this conflict, both involving reticulate evolution. The first explanation considers the alliances supported by nrDNA to be closer to the true species relationships. The corresponding classification would split *Arida* into two parts.

The second explanation considers the alliances supported by cpDNA to be closer to the species relationships for *Arida*. In supporting the group composed of *A. parviflora*, *A. turneri*, and *A. riparia*, cpDNA evidence suggested that the two lineages of *Arida* are closest relatives. In this case, the corresponding taxonomy would keep the two lineages together, retaining all species of *Arida* in the same genus. This is the classification adopted here because, in addition to cpDNA, several additional pieces of evidence support this treatment. All species of *Arida* have $n = 5$, all that have been investigated produce flavones, and hybridization experiments suggest much genetic similarity between the two lineages (Turner & Horne 1964; Turner et al. 1975; Stucky 1978; Hartman 1976, 1990; Nesom et al. 1990). This array of characteristics unites the species of *Arida* and distinguishes them from other taxa in the *Machaeranthera* complex; we interpret the conflicting results from nrDNA data as resulting from nrDNA introgression, as explained by Morgan (2003).

The following key is based in part on data in Hartman (1976, 1990), Nesom (2003), Nesom et al. (1990), and Turner (1986). It includes the new species *Arida mattturneri* (Turner & Nesom 2003).

KEY TO THE SPECIES OF *ARIDA*

1. Ray cypselae pappose (heads eradiate in *A. carnosa*).
   2. Leaves entire to toothed.
      3. Ray florets absent _____ **3. Arida carnosa**
      3. Ray florets present.
         4. Plants annual; leaf margins entire and glabrous or with 1–8 teeth per side, each spinulose tipped; involucres hemispheric, 10–16 mm wide when fresh; phyllaries linear lanceolate to oblong lanceolate, narrowly acute to acuminate or attenuate _____ **8. Arida riparia**
         4. Plants perennial, rhizomatous, forming vegetative rosettes; leaf margins essentially entire with 8–20 cilia or bristles per side, cilia 0.4–0.8(–1.5) mm long; involucres turbinate, 5–8 mm wide when fresh; phyllaries oblong ovate to obovate, broadly acute to short acuminate _____ **2. Arida blepharophylla**

2. Leaves (at least some) pinnatifid to bipinnatifid.
   5. Receptacles 8–11 mm wide; phyllary apices spreading to reflexed _____ **9. Arida turneri**
   5. Receptacles 2–7 mm wide; phyllary apices mostly appressed _____ **7. Arida parviflora**

1. Ray cypselae epappose (except in occasional plants).
   6. Mid-stems essentially glabrous or with few sessile glands.
      7. Leaves deeply pinnatifid; SW Colorado, N New Mexico, Utah, and E Arizona; Chihuahua and Coahuila, Mexico _____ **7. Arida parviflora**
      7. Leaves above basal rosette, if present, entire or toothed.
         8. Stems 10–45 cm long, weakly ascending to procumbent; SW Sonora, Mexico _____ **4. Arida coulteri**
         8. Stems 50–80 cm long, erect; W Texas _____ **6. Arida mattturneri**
   6. Mid-stems densely glandular pubescent.
      9. Involucres 3–6 mm tall, 5–10 mm wide; mid-stems densely glandular, also with longer, crisp, nonglandular hairs interspersed; S Nevada, S California, S Arizona; N Sonora, Mexico _____ **1. Arida arizonica**
      9. Involucres 6–8 mm tall, 10–15 mm wide; mid-stems densely glandular, nonglandular hairs absent; N Baja California Sur and adjacent W Sonora, Mexico _____ **5. Arida crispa**

1. Arida arizonica (R.C. Jackson & R.R. Johnson) D.R. Morgan & R.L. Hartman, comb. nov. BASIONYM: *Machaeranthera arizonica* R.C. Jackson & R.R. Johnson, Rhodora 69: 476, fig. 1. 1967. TYPE: U.S.A. ABSTRACT

Arida mattturneri Turner & Nesom, sp. nov., is described from collections made near Ruidosa in Presidio County, Texas. The plants are perennial, lavender-rayed, and occur in gypseous soils along shallow perennial streams and seeps. It is a member of *Machaeranthera* sect. *Arida*, now segregated as the genus *Arida*, and is similar to *Arida turneri* in significant respects, especially the bipinnately parted leaves. The new species is illustrated by photographs.

RESUMEN

Se describe **Arida mattturneri** Turner & Nesom, sp. nov., a partir de colecciones hechas cerca de Ruidosa, en Presidio County, Texas. Las plantas son perennes, rayadas de lavanda, y aparecen en suelos yesosos a lo largo de arroyos permanentes poco profundos y lugares rezumantes. Es un miembro de *Machaeranthera* sect. *Arida*, ahora segregado como género *Arida*, y es semejante a *Arida turneri* en aspectos importantes, especialmente en las hojas bipinnado-partidas. La nueva especie se ilustra mediante fotografías.

In the spring of 2001, Ms. Charmaine Delmatier of the U.S. Fish and Wildlife Service, Austin, Texas, collected sterile material of plants occurring along the gypseous, seepy walls of a canyon near Ruidosa, Texas (Presidio County), on the property of James Blumberg. She asked the senior author to identify the material concerned and, because of its peculiar habitat, there was little problem in tentatively identifying it as *Machaeranthera gypsitherma* Nesom, Vorobik, and Hartman (1990), a rare species previously unknown to Texas—it now apparently is extinct at its type locality in southern New Mexico and otherwise known from only a single population in Chihuahua, Mexico.

In a later visit to the Presidio County site (spring of 2003), to collect flowering material of this remarkable discovery, the present authors encountered essentially sterile material of yet another *Machaeranthera*, which is the subject of the present paper. The senior author, along with his son Matt and James Blumberg, revisited the site in the ensuing summer, at which time abundant flowering material of the plants concerned was collected. Examination of the material clearly indicates its status as a previously undescribed species.

We follow recent morphological and molecular studies and taxonomy of Ronald Hartman and David Morgan, as well as their forthcoming treatments

SIDA 20(4): 1417–1422. 2003

for the Flora of North America volumes of Asteraceae, in dividing the species of *Machaeranthera* (sensu Hartman 1990) among four segregate genera, including *Machaeranthera* sensu stricto but not including *Psilactis* (sensu Morgan 1993). Nomenclatural combinations to formally effect these taxonomic changes are in this current issue of Sida (Morgan & Hartman 2003).

Arida mattturneri B.L. Turner & G. Nesom, sp. nov. (**Figs. 1, 2**). TYPE: UNITED STATES. TEXAS: Presidio Co.: ca. 2.2 mi NNW of Ruidosa in 'Blumberg Canyon,' growing along perennial sulphur streams and around tinajas (ca. 30° 00' 00" N, 104° 44' 00" W), 20 Jul 2003, *Matt W. Turner 100* (HOLOTYPE: TEX; ISOTYPES: NY, SRSC).

Aridae turneri (Arnold & Jackson) Morgan & Hartman similis vestimento glanduloso, foliis bipinnatifidis lobis mucronatis, flosculis radii lavandulaceis, acheniis 1.0–1.5 mm longis nervis tenuibus numerosis, et pappo brevi, sed differt plantis perennibus foliis basalibus persistentibus, capitulis minoribus flosculis radii paucioribus, phyllariis oblongi-lanceolatis apicibus rotundati acutis, et flosculis disci pappo carenti.

Perennial herbs from a thick, lignescent taproot, caudex simple, stems, leaves, and phyllaries sticky-viscid from resin globules exuded by sessile or minutely stipitate glands, without other kinds of hairs; leaves and phyllaries with indurate mucros but not bristle-tipped. **Stems** erect, 50–80 cm tall. **Leaves** basal and cauline, basal in persistent rosettes, bipinnately parted, abruptly passing into merely pinnately parted lower and midcauline, gradually reduced upwards into entire, scale-like bracts; basal 4–6 cm long, 1.5–3.5 cm wide, broadly obovate in outline, ultimate segments ovate to linear-lanceolate or linear. **Heads** ca. 10–13, terminal on elongate bracteate peduncles 5–10 cm long, collectively forming a broad, open capitulescence; involucres campanulate, 5–6 mm high, 6–8 mm wide, phyllaries in 5–6 graduate series, oblong-lanceolate, 1.0–1.5 mm wide, outermost 1–2 mm long, innermost 5–6 mm long, distal 1/3–1/2 slightly widened then rounded-acute, green and slightly turgid-thickened; receptacles plane, ca. 5 mm wide, glabrous. **Ray florets** 9–13, pistillate, fertile, tubes ca. 1.5 mm long, ligules 9–10 mm long, lavender, markedly drooping in full bloom, tightly coiling during fruit maturity. **Disc florets** 40–100, fertile, corollas narrowly cylindric, yellow, 3.5–4.5 mm long, tubes 1.2–1.5 mm long, grading into the nearly glabrous throats 2.0–2.8 mm long, lobes 5, narrowly deltoid, erect, 0.3–0.5 mm long. **Achenes** 1.0–1.5 mm long, obovate-oblong in outline, 8–12 nerved, compressed but more or less 3(–4) sided, densely sericeous; pappus of disc achenes of numerous whitish bristles mostly 3–4 mm long, in 2–3 series and variable in length on a single achene, absent on ray achenes. Chromosome number, $2n = 10$ (Powell 2003, this issue).

The species is named for the senior author's son, Matt Warnock Turner, who participated in collection of type materials. Matt once confided to his father that if ever a plant were to be named for him, he would like it to be very distinct, relatively rare, and confined to Texas. With such a pitch, the senior Turner de-

spaired of ever finding a plant with such stringent 'cultural' parameters. The present novelty fulfills all such requirements, and with considerable filial pride, he has proposed the name concerned. The name also is appropriate, since its close relative, *Arida turneri* (Arnold & Jackson) Morgan & Hartman, is named for his father, thus both the plants and their eponymy bear a genetic connection. We also note that Matt is a first-rate systematist, evidenced by his account of the southwestern U.S.A. species of *Baileya* (Turner 1993) and the more eastern *Brazoria* (Turner 1996).

Following Hartman's conspectus (1990) of the genus *Machaeranthera*, the features of *Arida mattturneri* place it as a member of sect. *Arida* R.L. Hartman (now genus *Arida* (R.L. Hartman) Morgan & Hartman): leaves without bristle-tipped lobes, ray corollas lavender, achenes 1.5–3 mm long with thin walls and numerous, thin, superficial nerves, and pappus of disc achenes of relatively short bristles, absent on ray achenes. The chromosome number of *A. mattturneri* is *n* = 5 (from plants at the type locality; Powell 2003), which is constant for other species of *Arida*. All other species of *Machaeranthera* (sensu Hartman 1990) have chromosome numbers based on x = 4.

Among taxa of *Arida*, the only previously described species with bipinnatifid leaves is *A. turneri*, which is here hypothesized to be a close relative of the new species. Both species also occur in close proximity to saline or gypseous seeps and springs. The two are distinguished as follows:

1. Plants perennial; basal leaves persistent; involucres 6–8 mm wide, receptacles ca. 5 mm wide; phyllaries oblong-lanceolate, 1.0–1.5 mm wide, distal 1/3–1/2 slightly widened, then with rounded-acute apices; ray florets 9–13, corollas 10–12 mm long, achenes epappose; disc corollas 3.5–4.5 mm long _____ **Arida mattturneri**
1. Plants annual; basal leaves deciduous before flowering; involucres 12 -17 mm wide, receptacles 8–11 mm wide; phyllaries linear-lanceolate, 0.8–1.0 mm wide inner with narrowly acute to acuminate apices; ray florets 41–59, corollas 11–15 mm long, achenes pappose; disc corollas 4.5–6.0 mm long _____ **Arida turneri**

Arnold and Jackson (1978), as well as Hartman (1990), observed that the closest relative of *Arida turneri* is *A.* (*Machaeranthera*) *parviflora* (A. Gray) Morgan & Hartman. As in *A. turneri*, plants of *A. parviflora* are annual with basal leaves deciduous before flowering, but the latter differs primarily in its smaller and less dissected leaves and smaller heads (shorter and narrower involucres and fewer and shorter ray and disc florets). Ray achenes in some populations of *A. parviflora* are epappose but pappose in others. Differences between the two species appear to be mainly quantitative, but they have been collected in close proximity apparently without intergrades. Even so, morphological evidence is equivocal in suggesting relationships among the three species under consideration, and it remains to be discovered whether the two annuals (*A. turneri* and *A. parviflora*) or the two with bipinnatifid leaves (*A. turneri* and *A. mattturneri*) are more closely related.

FIG. 1. Upper photo: four plants of *Arida mattturneri* at the type locality, April 2003. Lower photo: same plants in flower at same site, July 2003.

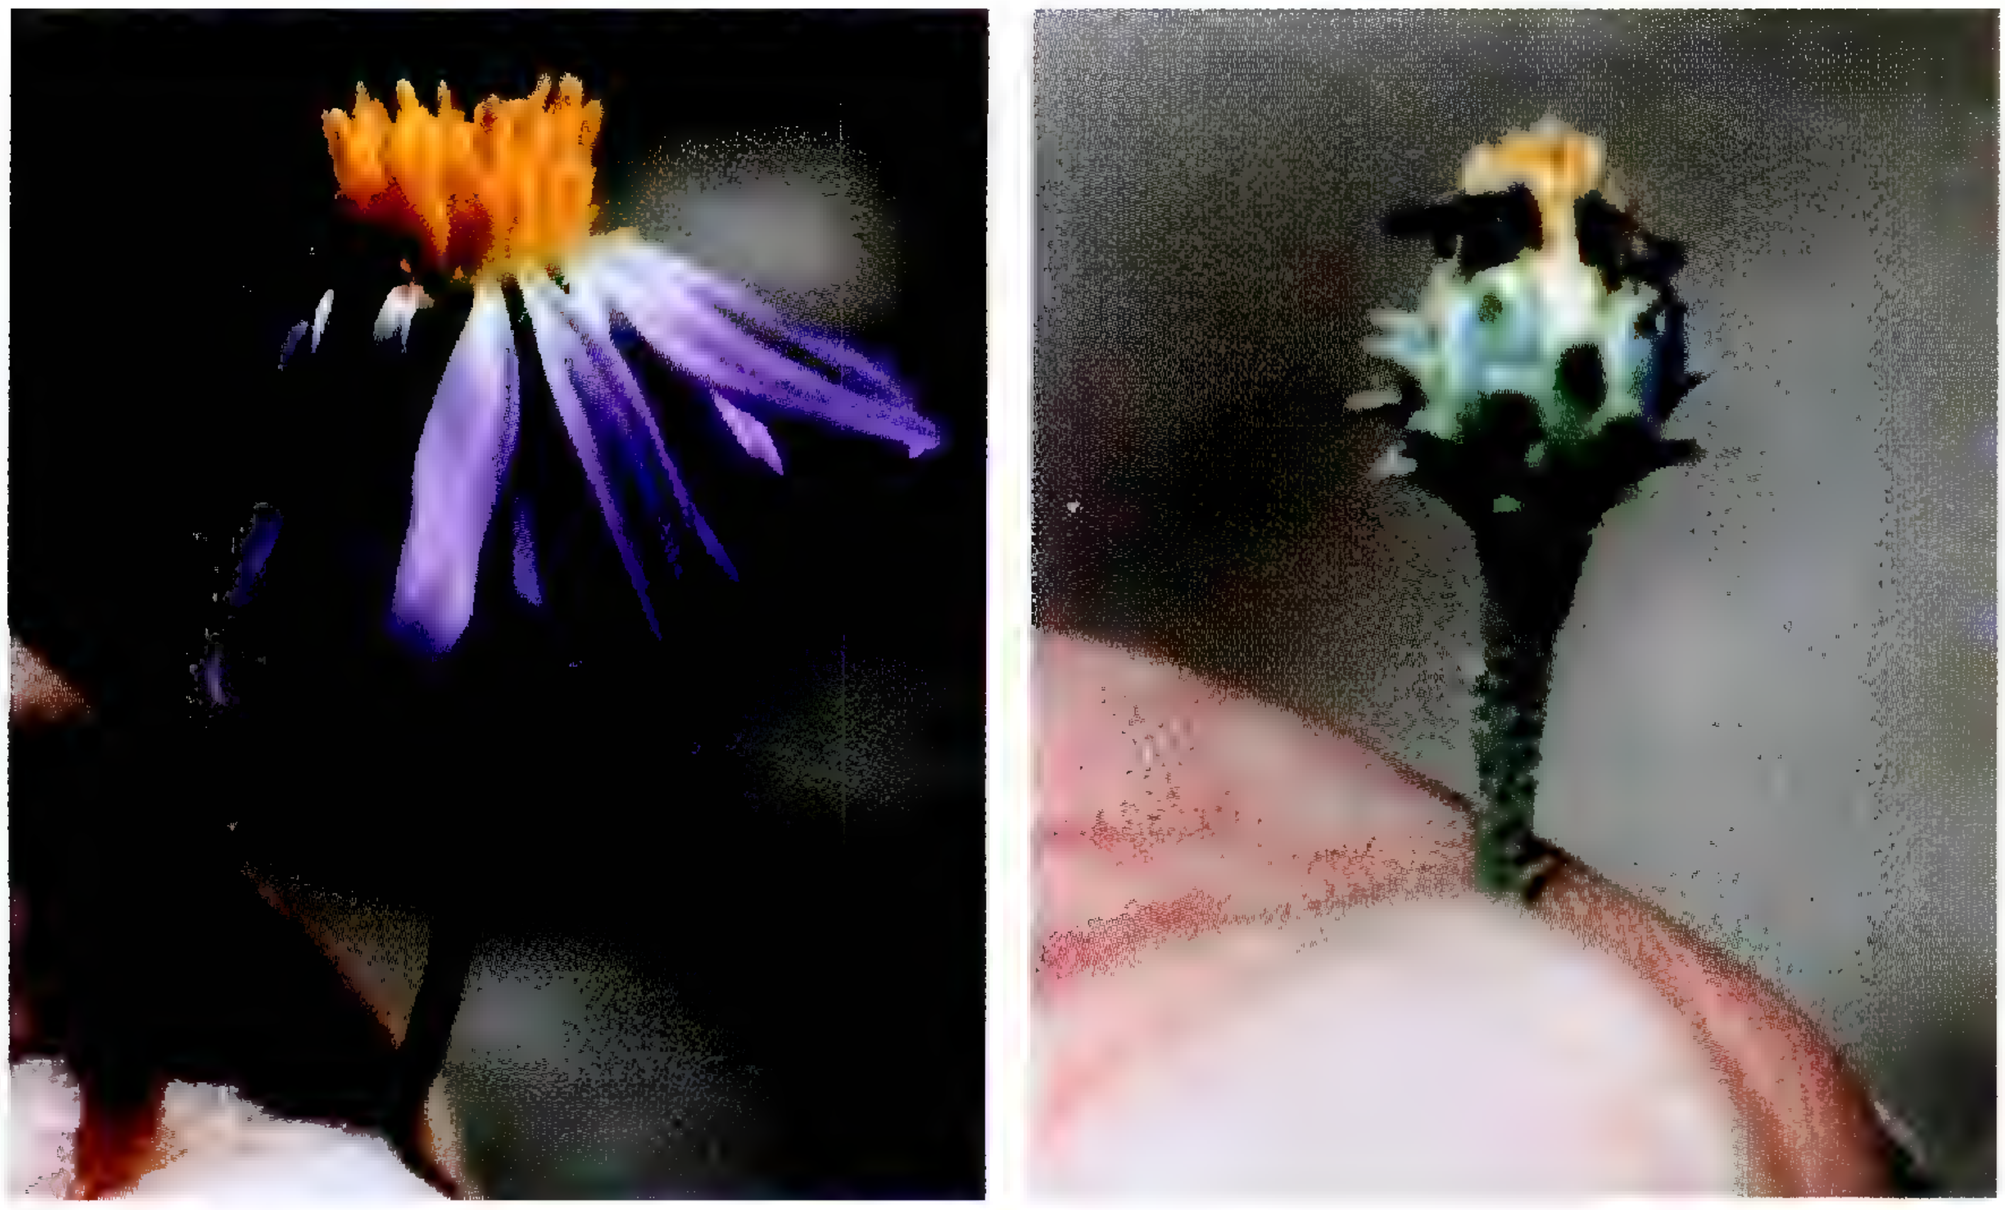

FIG. 2. Flowering heads showing (left, at anthesis) drooping ray corollas and (right, during fruit maturation) tightly coiled ray corollas and phyllaries with turgid, spreading apices.

When originally described, *Arida turneri* (as *Machaeranthera turneri*; Arnold and Jackson 1978) was primarily known by material from the vicinity of Meoqui, Chihuahua, Mexico, but subsequent collections have been made in Mpio. Julimes, Chihuahua, in the vicinity of Baños de San Diego (*McDonald 2549*, BRIT, TEX); *Nesom & Vorobik 5479*, TEX; and *Nesom 6543b*, TEX). The only other known extant locality for *Arida blepharophylla* (A. Gray) Morgan & Hartman (= *Machaeranthera gypsitherma*) also is Baños de San Diego, thus all three species in the discussion are rare and have similar ranges. *Arida mattturneri* is now the only one of the three known from only a single locality.

ACKNOWLEDGMENTS

We are grateful for the assistance of Mr. James Blumberg; he not only gave us free access to his property, he also accompanied the two Turners in their acquisition of type material. Thanks also to Mike Powell for providing the chromosome count and to Ron Hartman for review comments.

ABSTRACT

Revision of the group of species formerly placed in *Oerstedianthus* Lundell revealed that the group is synonymous with *Ardisia* subgenus *Graphardisia* Mez. This paper incorporates those taxa in the subgenus, necessitating further revision of subgenus *Graphardisia*, including an emended description of the subgenus, a key to the species and subspecies, along with updated descriptions of the four added taxa and new illustrations for each. Four additional taxa are recognized, including one new species: *Ardisia verdisepala* Ricketson & Pipoly, and one new combination: *Ardisia nigrescens* subsp. *donnellsmithii* (Mez) Ricketson & Pipoly. Seven binomials are relegated to synonymy within *A. tuerckheimii* Donn. Sm. In addition, *Ardisia nigrescens* Oerst., *A. nigrescens* subsp. *donnellsmithii* (Mez) Ricketson & Pipoly and *A. tuerckheimii* Donn. Sm. are lectotypified.

RESUMEN

Una revisión del grupo de especies anteriormente clasificadas dentro del género *Oerstedianthus* Lundell reveló que el grupo se ubica mejor dentro del género *Ardisia* subgénero *Graphardisia* Mez, y por lo tanto se relega el género a la sinonimia. El propósito del presente trabajo es para incorporar ese grupo dentro del subgénero, y actualizar su circunscripción, claves para identificar las especies y subespecies, descripciones de ellas y nuevas ilustraciones para cada una. Se reconocen cuatro taxa adicionales, que incluye una especie nueva para la ciencia: *Ardisia verdisepala* Ricketson & Pipoly, y una nueva combinación: *Ardisia nigrescens* subsp. *donnellsmithii* (Mez) Ricketson & Pipoly. Se relegan siente binomiales a la sinonimia bajo *A. tuerckheimii* Donn. Sm. Además, se lectotipifican *Ardisia nigrescens* Oerst., *A. nigrescens* subsp. *donnellsmithii* (Mez) Ricketson & Pipoly y *A. tuerckheimii* Donn. Sm.

INTRODUCTION

The pantropical genus *Ardisia* Sw. is the largest within the Myrsinaceae, containing perhaps as many as 500 species (Chen & Pipoly 1996). Its circumscription has been problematic owing to a lack of comprehensive treatment since that of Mez (1902) in Engler's *Das Pflanzenreich* over a century ago. In preparation of our treatment of the Myrsinaceae for *Flora Mesoamericana*, we have critically reexamined taxa segregated by Lundell from *Ardisia*, including *Gentlea* (Ricketson & Pipoly 1997), *Graphardisia* (Pipoly & Ricketson 1998), *Chontalesia* and species related to it, now known to belong to the genus *Hymenandra* (Pipoly & Ricketson 1999a), *Zunilia* which is now known to belong to *Ardisia* subgen. *Graphardisia* (Pipoly & Ricketson 1999b), *Ardisia rarescens* Standl. which was

SIDA 20(4): 1423–1447. 2003

placed in *Amatlania* by Lundell and is now known to belong to *Ardisia* subgen. *Acrardisia* (Pipoly & Ricketson 2000), *Auriculardisia*, *Amatlania* and *Valerioanthus* now all belonging to *Ardisia* subgen. *Auriculardisia* (Ricketson & Pipoly 2003) and the segregate genera, *Yunckeria* Lundell (=*Ctenardisia* Ducke) and *Ibarrea* Lundell (=*Ardisia* subgen. *Ardisia*). Since our study of the subgenus *Graphardisia* (Pipoly & Ricketson 1998, 1999b), including Lundell's segregate genera *Graphardisia* and *Zunilia*, it has become evident that the taxa comprising the segregate genus *Oerstedianthus* (Lundell 1981) are best placed within *Ardisia* subgenus *Graphardisia*.

According to Lundell (1981:139–140), "The genus [*Graphardisia*] is related to *Oerstedianthus* Lundell." He separated the two as follows:

"Filaments strictly glabrous; stems and inflorescence glabrous; punctations of all parts dense and blackish; bracts and bractlets usually foliaceous and often persistent; sepals and petals large, accrescent, usually blackened, usually ribbed or with dense elevated black glands _____ **Graphardisia**

Filaments pubescent with gland-tipped hairs; stems and inflorescence rarely glabrous, usually puberulent, hirtellous or dense hirsute tomentose; punctations of all parts conspicuous but not prominently raised, pellucid or rarely blackish; bracts and sepals small, not accrescent; sepals not ribbed with glands _____ **Oerstedianthus**"

However, our studies of *Ardisia* subgenus *Graphardisia* (Pipoly & Ricketson 1998, 1999b) have clearly shown the presence of raised or sessile glandular-papillate filaments in all taxa. In addition, because we are not sure of the polarity of this character state, or if it can have multiple origins, its utility is dubious. Foliar and other punctations are said to be inconspicuous in the taxa newly added in this work, but they are normally prominent and occasionally conspicuous. Finally, the sepals are generally small, but they are comparable to those found in other members of subgenus *Graphardisia*, (i.e., *Ardisia bartlettii* Lundell and *A. weberbaueri* Mez). Lundell (1981:141) also notes: "*Oerstedianthus* is related to *Graphardisia* (Mez) Lundell. Both have similar linear-lanceolate anthers which dehisce by apical pores." Therefore, we find it necessary to relegate the genus *Oerstedianthus* Lundell to synonymy under *Ardisia* subgenus *Graphardisia*.

TAXONOMIC TREATMENT

Ardisia subgenus **Graphardisia** Mez in Engl., Pflanzenr. IV. 236 (Heft 9):78. 1902; Lundell, Wrightia 3:192–198. 1966. *Graphardisia* (Mez) Lundell, Phytologia 48:139. 1981; Lundell, Phytologia 59:429–433. 1986. TYPE: *Ardisia opegrapha* Oerst. (LECTOTYPE, designated by Lundell, Phytologia 48:139. 1981).

Oerstedianthus Lundell, Phytologia 48:141. 1981. Syn. Nov. TYPE: *Ardisia nigrescens* Oerst. 1861:130. 1862. *Oerstedianthus nigrescens* (Oerst.) Lundell, Phytologia 48:141. 1981.

Zunilia Lundell, Phytologia 49:353. 1981. TYPE: *Ardisia sexpartita* Lundell, Wrightia 3:29. 1962. *Zunilia sexpartita* (Lundell) Lundell, Phytologia 49:354. 1981.

Subshrubs to trees. Branchlets mostly terete, glabrous, puberulent, hirsute or

rarely, glandular-granulose. **Leaves** petiolate; blades membranous to subcoriaceous, densely and prominently black (rarely pellucid-) punctate and punctate-lineate, the margins entire to crenulate or serrate. **Inflorescence** terminal, rarely lateral, pinnate to tripinnately paniculate, pyramidal to obpyramidal rarely globose, the ultimate branches corymbose, at times in high anthotactic spirals and thus appearing umbellate, the rachis often densely and prominently black punctate and punctate-lineate; inflorescence and floral bracts minute to foliaceous, caducous to persistent, often resembling the vegetative leaves but acropetally reduced in size. **Flowers** 5 or 6-merous, densely and prominently black punctate and punctate-lineate; calyx with sepals free or nearly free, large, accrescent and clasping fruits at maturity; corolla white, pink, lavender or purple, rotate, the lobes imbricate in bud, basally short-connate and sparsely to densely yellow glandular-granulose within at the base, densely and prominently black punctate-lineate; stamens inserted at corolla tube base, the filaments basally connate to form an inconspicuous tube, the tube free from the corolla tube, the apically free portions of the filaments with scattered yellow glandular-granulose or glandular-papillate, less than half the length of the anthers, the anthers ovoid-lanceoloid, linear or lanceoloid, prominently apiculate, dehiscent by subapical pores; ovary globose, the style slender, equaling the sepals, 2—3 times longer than the ovary, the placenta apiculate, the ovules pluriseriate, biseriate, or apparently uniseriate (few in number and in a very high anthotactic spiral). **Fruit** globose or oblongoid, densely punctate and punctate-lineate, basally surrounded by persistent, clasping sepals.

Distribution.—A small distinctive subgenus of seven species with nine subspecies found from Mexico to Bolivia and adjacent Brazil.

Ecology.—Members of the subgenus occur in diverse humid to pluvial vegetation types, lowland, premontane, montane, and cloud forests.

The subgenus is defined by: 1) black, or rarely, reddish-black, punctations or punctate-lineations on all leaf and floral parts; 2) sepals often accrescent and usually clasping the developing fruit; 3) linear-lanceolate, concolorous, apiculate anthers with subapical, poricidal dehiscence; and 4) styles that are 2–3 times longer than the ovary. Among the species of *Ardisia*, it is notable that the branchlets, petioles and inflorescence rachises among species of subg. *Graphardisia* are never tomentose, but may be glabrous, puberulent, rarely hirsute or glandular-granulose. Therefore multicellular trichomes are not found in the subgenus. Species of the subgenus are often used for home decoration and for use in Christian churches for religious holidays (Pipoly, pers. obs.).

KEY TO TAXA OF *ARDISIA* SUBGENUS *GRAPHARDISIA*

1. Stoloniferous subshrubs mostly less than 1(–2) m tall; leaf blade margins sharply and irregularly dentate; corolla tube and filaments yellow glandular-granulose; Amazonian Ecuador to Bolivia and adjacent Brazil. _____ **A. weberbaueri**

1. Shrubs to small trees (0.5–)2–6(–30) m tall, without stolons; leaf blade margins entire, undulate or crenulate to serrate; corolla tube yellow glandular-granulose; filaments glabrous or sessile to stalked glandular-papillate; Mexico to the Chocó Region of Colombia.
   2. Sepals oblong, 4.2–8 mm long, apically broadly rounded to obtuse, the margins entire _____ **A. opegrapha**
      3. Inflorescence obpyramidal; leaf blades oblanceolate or rarely obovate, 3.5–7.5(–8) cm wide, 3 or more times longer than wide.
         4. Floral bracts caducous; stamens 5.2–6.5 mm long; filaments 2.5–3 mm long; sepals 5–8 mm long _____ **A. opegrapha** subsp. **opegrapha**
         4. Floral bracts persistent; stamens 3.8–5 mm long; filaments 1.5 2 mm long; sepals 4.2–5.2 mm long _____ **A. opegrapha** subsp. **wagneri**
      3. Inflorescence globose; leaf blades elliptic to broadly elliptic (7.5)8 14.5 cm wide, 2 2.5 times longer than wide _____ **A. opegrapha** subsp. **paquitensis**
   2. Sepals ovate, 1.5–3.2(–4) mm long, apically acute to rounded, tne margins subentire to entire or erose.
      5. Corolla lobes ovate, elliptic or lanceolate; filaments glabrous; Panama and Colombia _____ **A. bartlettii**
         6. Sepals 1.5 1.8 mm long; petal lobes 6–6.5 mm long; stamens 3.5– 4.8 mm long; style base tapering; tall wet forests _____ **A. bartlettii** subsp. **bartlettii**
         6. Sepals 2 2.5 mm long; petal lobes 7–8 mm long; stamens 4.5–5.7 mm long; style base stylopodic; strand vegetation and beach forests _____ **A. bartlettii** subsp. **lilacina**
      5. Corolla lobes oblong; filaments with sessile papillae to stalked-glandular-papillate; Oaxaca, Mexico to Nicaragua.
         7. Branchlets and inflorescence rachis glabrous; anthers 3–3.2 mm long _____ **A. verapazensis**
            8. Corolla lobes 6.5 6.7 mm long; free portion of filaments 3.3–3.4 mm long; style 3–3.1 mm long; fruit 6.5 -9 mm in diam.; fruiting style 7–8.6 mm long, usually only the basal portion persistent _____ **A. verapazensis** subsp. **verapazensis**
            8. Corolla lobes 5.7–5.9 mm long; free portion of filaments 2.6–2.8 mm long; style 5.5–5.9 mm long; fruit 5 6.1 mm in diam., fruiting style 8.8 9.4 mm long, the entire style usually persistent _____ **A. verapazensis** subsp. **cucullata**
         7. Branchlets and inflorescence rachis long-hirsute with reddish hairs or very sparsely to densely puberulent of simple trichomes; anthers 3.2–5.1 mm long.
            9 Branchlets very sparsely to densely puberulent _____ **3. A. tuerckheimii**
            9. Branchlets scattered to densely long hirsute with reddish hairs.
               10. Calyx lobes oblong, 3.4–3.8 mm; corolla lobes 8–8.4 mm; filaments as wide as anthers, the anthers basally hastate. _____ **2. A. verdisepala**
               10. Calyx lobes ovate, 1.9–2.7 mm; corolla lobes 4.8–8 mm; filaments abruptly constricted apically, the anthers basally subcordate __ **1. A. nigrescens**
                  11. Leaf margins crenulate or serrate; calyx lobes 1.9–2.1 mm _____ **1a. A. nigrescens** subsp. **nigrescens**
                  11. Leaf margins mostly entire to slightly crenulate or serrate; calyx lobes 2.2–2.7 mm _____ **1b. A. nigrescens** subsp. **donnellsmithii**

1. Ardisia nigrescens Oerst., Vidensk. Meddel. Dansk Naturhist. Føren

Kjøbenhavn 1861:130. 1862. *Icacorea nigrescens* (Oerst.) Standl., Contr. U.S. Natl. Herb. 23:1109. 1924. *Oerstedianthus nigrescens* (Oerst.) Lundell, Phytologia 48:142. 1981. TYPE. MEXICO. VERACRUZ: Prope Colipa, without elev., Mar 1842 (fr), *F. Liebmann 28B* (LECTOTYPE: C, here designated, F neg. # 22952, in part).

Shrubs or small trees 1–12 m tall, to 7.5 cm in diam. **Branchlets** 1–5 mm in diam., densely long hirsute reddish hairs throughout. **Leaves:** with leaf blades membranous to chartaceous, ovate or elliptic to oblong, 3.5–18.2 cm long, 1.5–8.2 cm wide, with an acumen 0.8–2.1 cm long, basally obtuse, inconspicuously to conspicuously, often prominently punctate and punctate-lineate, sparsely hispid above and below, often densely hispid along the midrib above, densely hirsute along the midrib below, the secondary veins 15–24 pairs, the margins entire or crenulate to serrate; petioles 0.5–1.6 cm long, densely hispid along above, densely hirsute below. **Inflorescences** 1.5–6 cm long, 2–8 cm wide, shorter than the leaves, the rachis with dense, long hirsute with reddish hairs, the branches 3–18-flowered corymbs; peduncles nearly absent to 1.2 cm long, densely long hirsute with reddish hairs; inflorescence branch bracts oblong to oblanceolate, 4–25 mm long, 1–14 mm wide, scattered long hirsute with reddish hairs; floral bracts similar to the inflorescence bracts but, when present, to 0.3–0.8 mm long, 0.1–0.2 mm wide; pedicels 0.7–1.4 cm long, conspicuously and prominently punctate and punctate-lineate, with densely long hirsute simple reddish hairs. **Flowers** 5–6-merous; calyx lobes ovate, 1.9–2.7 mm long, 1.1–1.5 mm wide, apically acute, sparsely hirsute outside, glandular-granules within near the base, the margins entire, densely hirsute-ciliolate; corolla 6.5–10 mm long, the tube 1.2–2.4 mm long, the lobes 4.8–8 mm long, 2.2–4.8 mm wide; stamens 4.6–6 mm long, the filaments 1.5–2.8 mm long, the staminal tube 0.5–1 mm long, the apically free portion abruptly constricted 1–2.1 mm long, the anthers 3.3–4.5 mm long, 0.8–1.1 mm wide; pistil 5–6.4 mm long, the ovary 0.8–1.2 mm long, the style 4–4.7 mm long, the ovules 5–7. **Fruits** 5.5–7.3 mm in diam.

In Oersted's (1862: p. 130) original description he cites two localities, both collected by Liebmann: "*Crescit in Mexico, ubi cl. Liebmann Martio fructificantem prope Colipa et Jecaltepec legit.*" The Museum Botanicum Hauniense (C) clearly houses the two collections used by Oersted, "Mexico, Prope Jecaltepec, Mar. 1842 (fr), *F. Liebmann 28A*" and "Mexico, Prope Colipa, Mar 1842 (fr), *F. Liebmann 28B.*" Both collections are in fruit, but the *28A* specimen has narrower leaves with no attached fruits and the *28B* specimen has wider leaves with many attached fruits. Unfortunately, the photograph taken by J.F. Macbride during the Field Museum of Natural History's project to photograph European types (F neg. no. 22952), is a combination of both specimens, although primarily of the *28B* specimens. Thus, because the *28B* specimen is more complete and more widely seen *via* the F photograph, we elect to designate the *Liebmann 28B* (C) specimen as the lectotype. Although, C.L. Lundell annotated the *28A* specimen in 1966 as the "TYPE!" he did not formally publish a lectotypification.

Within *Ardisia* subgen. *Graphardisia*, *A. nigrescens* is most closely related to *A. verdisepala*, because of the long, hirsute, with reddish tricomes throughout the vegetative parts of the plant. However, *Ardisia nigrescens* may be easily distinguished by its shorter, ovate calyx lobes (1.9–2.7 mm long), and shorter corolla lobes (4.8–8 mm long). *Ardisia verdisepala* has longer oblong calyx lobes (3.4–3.8 mm long) and longer corolla lobes (8–8.4 mm long).

1a. Ardisia nigrescens Oerst. subsp. **nigrescens (Fig. 1).**

Shrub or small tree 1.5–5 m tall. **Branchlet** slender, terete, 1–3 mm in diam., with dense, long hirsute simple reddish hairs throughout. **Leaves:** with leaf blades membranous, elliptic, 3.5–11.2 cm long, 1.5–5.2 cm wide, apically abruptly acuminate, the acumen 0.8–1.4 cm long, basally obtuse, midrib impressed above, prominently raised below, the secondary veins 15–24 pairs, prominulous above, prominently raised below, inconspicuously to conspicuously, often prominently punctate and punctate-lineate, sparsely hispid above and below, often densely hispid along the midrib above, densely hirsute along the midrib below, the margins crenate to serrate, flat; petioles slender, canaliculate, 0.5–1.1 cm long, densely hispid along above, densely hirsute below. **Inflorescence** terminal, rarely lateral, erect, pinnate paniculate, 1.5–5 cm long, 2–5.5 cm wide, shorter than the leaves, the rachis with dense, long hirsute simple reddish hairs, the branches 3–7 flowered corymbs; peduncles nearly absent to 1 cm long, with dense, long hirsute simple reddish hairs; inflorescence branch bracts caducous, membranous, oblong to oblanceolate, 2–2.5 cm long, 0.1–0.4 cm wide, apically acute, basally acute on sessile or short petioles, the veins prominent, conspicuously and prominently punctate and punctate-lineate, with scattered, long hirsute, simple reddish hairs, the margins entire; floral bracts similar to the inflorescence bracts but, 0.3–0.8 mm long, 0.1–0.2 mm wide; pedicels slender, terete, 0.7–1.4 cm long, conspicuously and prominently punctate and punctate-lineate, with dense, long hirsute simple reddish hairs. **Flowers** 5–6-merous, white to pink; calyx lobes membranous, ovate to narrow ovate, 1.9–2.1 mm long, 1.1–1.3 mm wide, apically acute, conspicuously and prominently punctate and punctate-lineate, sparsely hirsute outside, granular-glandules within near the base, the margins entire, densely hirsute-ciliolate; corolla membranous, 6.5–10 mm long, the tube 1.2–2.4 mm long, the lobes oblong, 4.8–8 mm long, 2.2–4.8 mm wide, apically acute to rounded, conspicuously and prominently punctate and punctate-lineate, glabrous except with scattered yellow papillae at the base within, the margins entire, erose; stamens 5–6 mm long, the filaments 1.9–2.8 mm long, the staminal tube 0.5–1 mm long, the apically free portions abruptly constricted, 1.3–2.1 mm long, epunctate, with scattered yellow papillae near the base, the anthers free, lanceolate, 3.5–4.4 mm long, 0.9–1.1 mm wide, apically apiculate, basally subcordate, the connective inconspicuously punctate; pistil 5–5.5 mm long, glabrous, inconspicuously punctate, the ovary ovate, 0.8–1.1 mm long, the style 4–

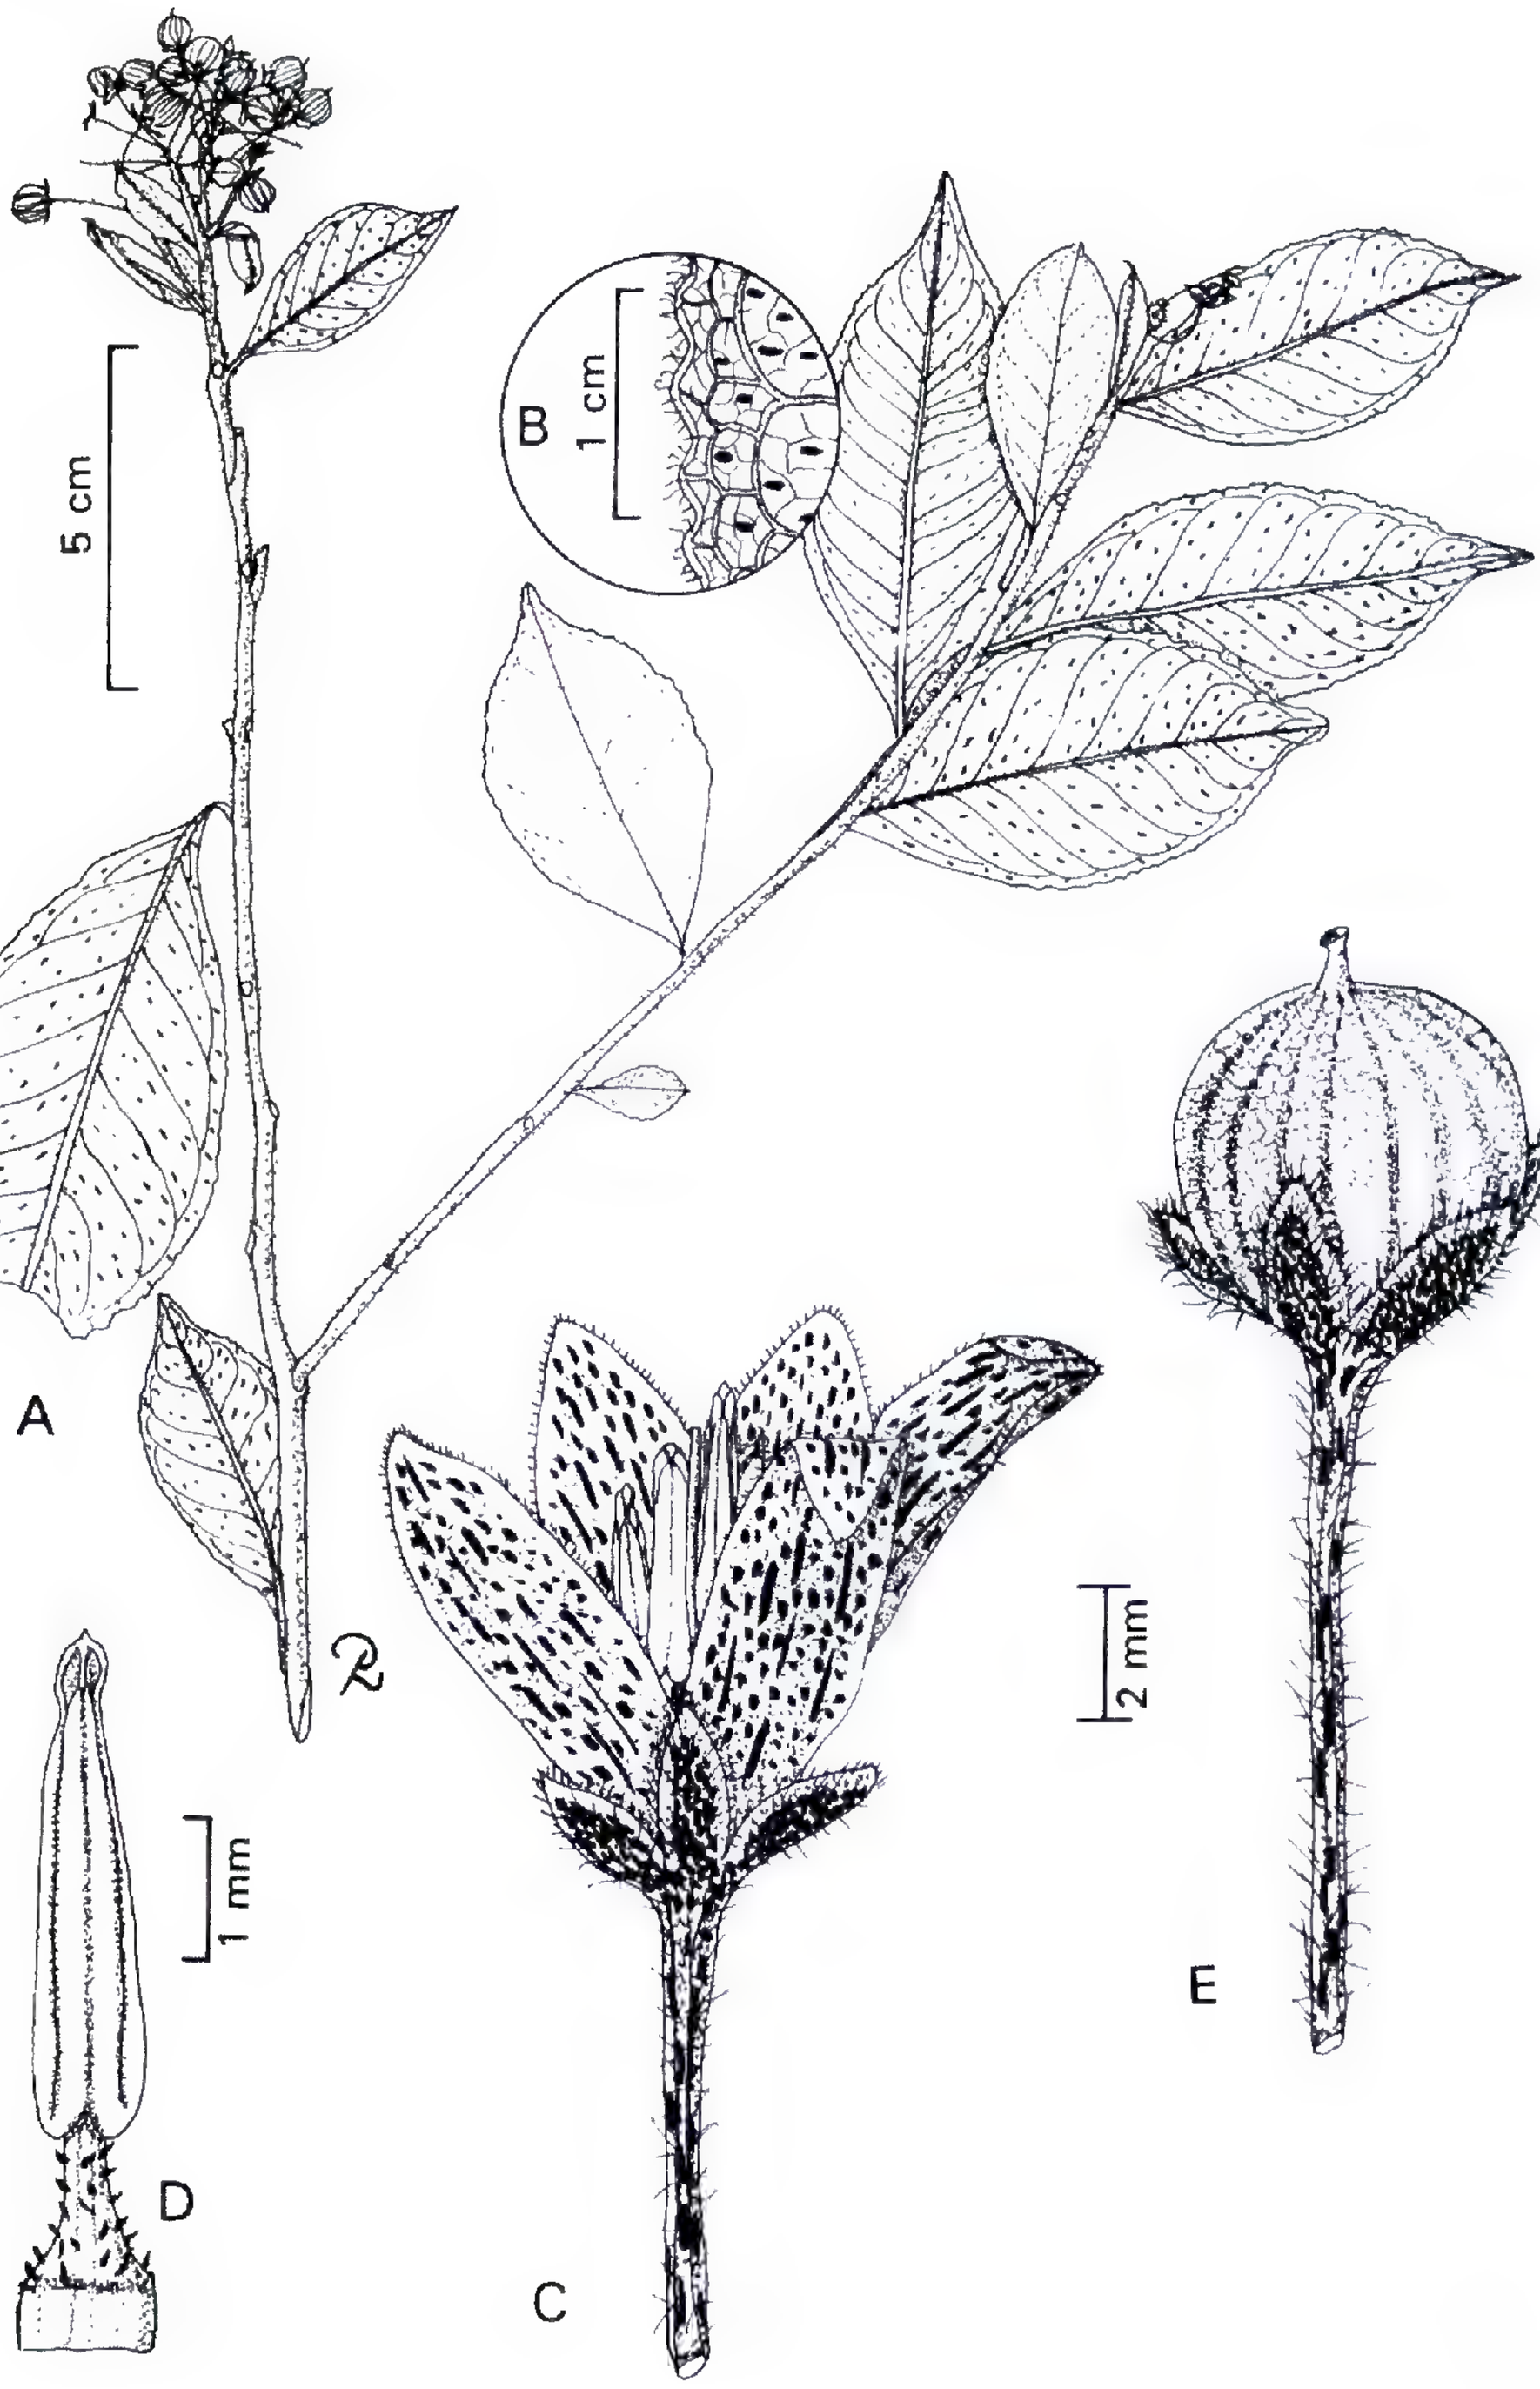

FIG. 1. *Ardisia nigrescens* Oerst. subsp. *nigrescens* **A.** Flowering branch. **B.** Detail of abaxial leaf surface. **C.** Flower. **D.** Stamen, showing adaxial surface. **E.** Fruit. A–B, E drawn from lectotype, *F. Liebmann 28B* (C). C & D drawn from *H. Hernández & R. Torres 813* (MO).

4.4 mm long, stylipodic, inconspicuously punctate and punctate-lineate, the ovules 5–7. **Fruit** globose to oblong, 6.9–7.3 mm long, 6.2–6.6 mm in diam., inconspicuously punctate and punctate-lineate.

Distribution.—*Ardisia nigrescens* subsp. *nigrescens* is known from Mexico (Puebla, San Luis Potosí, Oaxaca, Veracruz, Chiapas and Tabasco) and in Nicaragua (Jinotega and Zelaya). It grows at 50–1000 m elevation.

Ecology and conservation status.—Subsp. *nigrescens* occurs in primary deciduous and evergreen, lower montane rain forests. This subspecies does not appear to be threatened.

Etymology.—The epithet is based on the latin 'niger' or 'nigrescens' meaning 'becoming black' and refers to the black hispid trichomes.

Ardisia nigrescens subsp. *nigrescens* is most closely related to subsp. *donnellsmithii* because they have similar reddish, hirsute trichomes and ovate calyx lobes. However, subsp. *nigrescens* has crenulate or serrate leaf margins and shorter calyx lobes (1.9–2.1 mm long), whereas subsp. *donnellsmithii* has mostly entire to slightly crenulate or serrate leaf margins and longer calyx lobes (2.2–2.7 mm long).

margins entire, erose; stamens 4.6–5.5 mm long, the filaments 1.5–2 mm long, the staminal tube 0.5–0.7 mm long, the apically free portions abruptly constricted, 1–1.5 mm long, epunctate, with scattered yellow papillae near the base, the anthers free, lanceolate, 3.3–4.5 mm long, 0.8–1.1 mm wide, apically apiculate, basally subcordate, the connective inconspicuously punctate; pistil 5.4–6.4 mm long, glabrous, inconspicuously punctate, the ovary ovate, 0.8–1.2 mm long, the style 4–4.7 mm long, inconspicuously punctate and punctate-lineate, the ovules 12–15. **Fruit** globose, 5.5–7.2 mm long, 6.2–6.6 mm in diam., inconspicuously punctate and punctate-lineate.

Distribution.—*Ardisia nigrescens* subsp. *donnellsmithii* is known from Mexico (Chiapas), Belize (Stann Creek and Toledo) and Guatemala (Alta Verapaz, Huehuetenango and Petén). It grows from 50–950 m.

Ecology and conservation status.—Subsp. *donnellsmithii* occurs in lower montane rain forest.

Etymology.–This taxon was dedicated to John Donnell Smith (1829–1928), who collected extensively in Guatemala and Central America.

In Mez's (1903) original description he lists two collections by *H. von Türckheim* numbers *7766* and *7918*, both in the Mez Herbarium (B). These original collections were destroyed in 1943 during WWII, necessitating the need to select a lectotype. Although, C.L. Lundell labeled the US sheet of *H. von Türckheim 7766* as the "Holotype," he failed to actually publish a lectotypification of the collection. However, from the available material, the US sheet is the best material, and we here select it as the lectotype for this taxon. The only known sheet of *H. von Türckheim 7918* is also at US but is missing the inflorescence and has only a few loose fruits. Unfortunately, Mez (1920) re-described this same material as *Ardisia multilineata* using the same *H. von Türckheim* collections, thus making this name superfluous.

Specimens examined. **MEXICO. Chiapas:** Mpio. Ocozocoautla, 46 km N of Ocozocoautla on road to Mal Paso, 700 m, 8 Oct 1974 (fr), *D. Breedlove 38709* (DS, LL-2 sheets); Mpio. Palenque, 50 km SW of Palenque on road to Ocosingo near Colonia Úrsulo Galvano, 370 m, 9 Nov 1980 (fr), *D. Breedlove 47348* (CAS); Mpio. La Libertad, 15–20 km towards Chancala on road to Bonampak from the Palenque-Ocosingo road, 280 m, 4 Jan 1981 (fr), *D. Breedlove 49160* (LL, NY); Mpio. Ocosingo, on ridges near lake at Naja, 300 m, 3 Mar 1981 (fr), *D. Breedlove 49970* (LL, MO, NY); Mpio. Chilón, near and along road to Pozo Cuevas above Agua Azul, 600 m, 14 Jan 1982 (fr), *D. Breedlove & F. Almeda 57228* (LL, MO); Mpio., La Independencia, ridges 45–50 km E of Lagos de Montebello National Park on road to Ixcán from Santa Elena, 760 m, 22 Jan 1982 (f), *D. Breedlove 57759* (CAS); Mpio. Ocosingo, S of Santo Domingo on road to Bonampak and Echeverría from Chancala, 455 m, 25 Jan 1982 (fr), *D. Breedlove & F. Almeda 57927* (MO); Mpio. Ocosingo, near Laguna Ocotal Grande, ca. 25–30 km SE of Monte (Cerro) Líbano, ca. 950 m, 10 Aug 1954 (fl), *R. Dressler 1637* (GH, US); Río Salinas, without elev., 8 Feb 1964 (fl), *C. 2. Ardisia verdisepala Ricketson & Pipoly, sp. nov. **(Fig. 3)**. TYPE. MEXICO. CHIAPAS: Mpio. Ocosingo, 15 km SW of Ocosingo on road to San Cristóbal Las Casas, 1,372 m, 1 Sep 1981 (fl), *D. Breedlove 52591* (HOLOTYPE: MO; ISOTYPES: CAS, GH, LL, NY).

Propter ramulosque rhachides inflorescentiarum longi-hirsutos A. nigrescens valde arcte affinis sed ab ea lobis calycinis oblongisque (non ovatisque) 3.4–3.8 (nec 1.9–2.7) mm longis praeclare distat.

Shrub to small tree 1.2–6.1 m tall. **Branchlets** slender, terete, 1–2.5 mm in diam., with dense, long hirsute simple reddish hairs throughout. **Leaves:** with leaf blades, membranous, elliptic to oblong, 3.3–10.2 cm long, 1.5–4.8 cm wide, apically abruptly acuminate, the acumen 0.5–1.6 cm long, basally acute to obtuse, the midrib impressed above, prominently raised below, the secondary veins 12–19 pairs, prominulous above, prominently raised below, conspicuously and prominently punctate and punctate-lineate, sparsely hispid above and below, often densely hispid along the midrib above, densely hirsute along the midrib below, the margins serrate, flat; petioles slender, canaliculate, 3.5–8 mm long, with dense, long hispid reddish hairs above and below. **Inflorescences** terminal, rarely lateral, erect, pinnately paniculate, 3–6 cm long, 3–6.5 cm wide, shorter than the leaves, the rachis with dense, long hirsute, simple reddish hairs, the branches 5–7 flowered corymbs; peduncles nearly absent to 1.5 cm long, with dense, long hirsute, simple reddish hairs; inflorescence branch bracts caducous, membranous, oblong to obovate or oblanceolate, 7.5–15.5 mm long, 3.5–6 mm wide, apically acute, basally acute on sessile or short petioles, the veins prominent, conspicuously and prominently punctate and punctate-lineate, with scattered to dense, long hirsute, simple reddish hairs, the margins entire; floral bracts apparently absent above, with no apparent scars, below similar to the inflorescence branch bracts but, early caducous, usually linear, 3.8–6.6 mm long, 1.3–1.5 mm wide; pedicels slender, terete, 1.5–2.5 cm long, conspicuously and prominently punctate and punctate-lineate, with dense, long hirsute, simple reddish hairs. **Flowers** 5-merous, white to pink or reddish; calyx lobes membranous, narrowly oblong, 3.4–3.8 mm long, 1.2–1.7 mm wide, apically acute to rounded, conspicuously and prominently punctate and punctate-lineate, sparsely hirsute outside, glabrous within, the margins entire, scattered hirsute-ciliolate; corolla membranous, 9.2–9.8 mm long, the tube 1.2–1.4 mm long, the lobes oblong, 8–8.4 mm long, 3.2–5.4 mm wide, apically acute to rounded, conspicuously and prominently punctate and punctate-lineate, glabrous except with

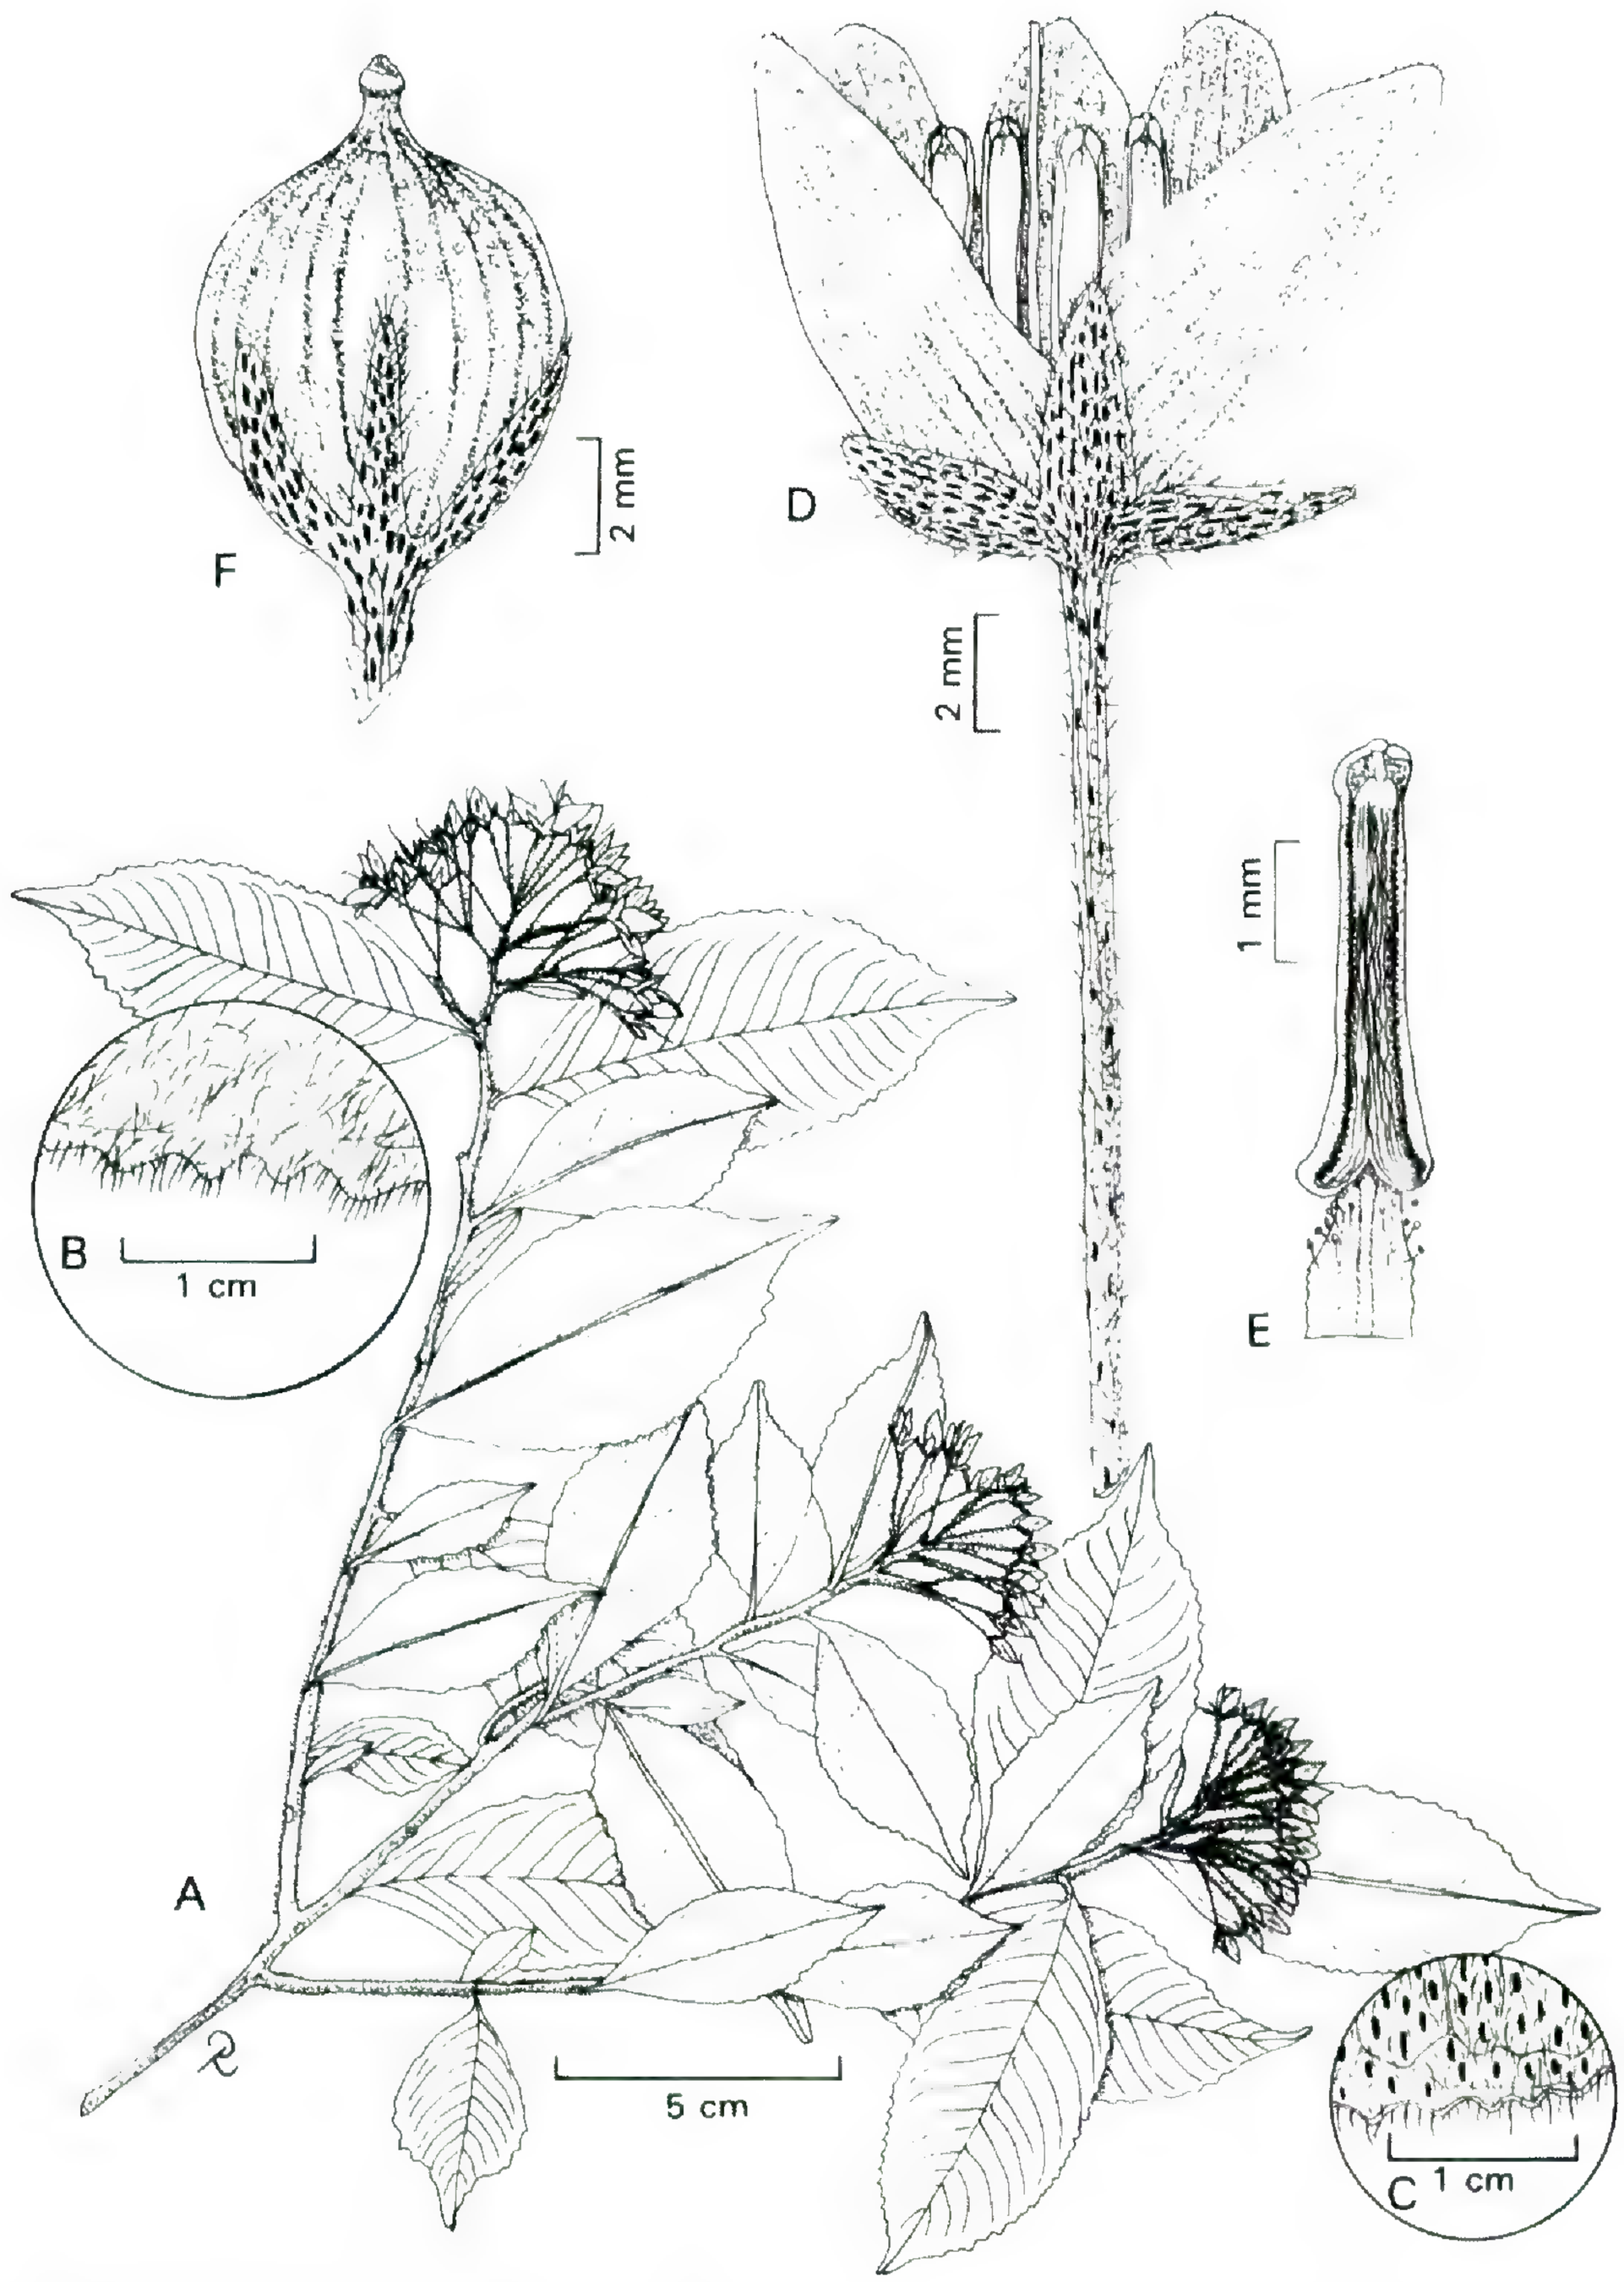

FIG. 3. *Ardisia verdisepala* Ricketson & Pipoly. **A.** Flowering branch. **B.** Detail of adaxial leaf surface. **C.** Detail of abaxial leaf surface. **D.** Flower. **E.** Stamen, showing adaxial surface. **F.** Fruit. A–D drawn from holotype, *D. Breedlove 52591* (MO). F drawn from *A. Méndez Ton 5667* (MO).

scattered yellow papillae at the base within, the margins entire, erose; stamens 5–5.8 mm long, the filaments 1.7–2.2 mm long, the staminal tube 0.5–0.7 mm long, the apically free portions as wide as the anthers, 1.4–1.7 mm long, epunctate, with scattered yellow papillae near the base, the anthers free, lanceolate, 3.8–4.3 mm long, 1–1.2 mm wide, apically apiculate, basally hastate, the connective inconspicuously punctate; pistil 5.5–6.8 mm long, glabrous, inconspicuously punctate, the ovary ovate, 1–1.5 mm long, the style 4.5–5.6 mm long, inconspicuously punctate and punctate-lineate, the ovules 14–17. **Fruit** globose, 5.4–7 mm long, inconspicuously punctate and punctate-lineate.

Distribution.—*Ardisia verdisepala* is endemic to the area around Ocosingo, Chiapas, Mexico. It grows from 550–1,372 m.

Ecology and conservation status.—*Ardisia verdisepala* occurs in evergreen pine-oak, lower montane and montane rain forests. Although, no specimens have been collected since the 1980s, it seems to be locally common and not presently threatened.

Etymology.—The epithat *verdisepala* comes from the greenish color of the sepals, which is evident because of the reduced number of punctations on the calyx lobes.

Ardisia verdisepala has affinities to *A. nigrescens* because of the similar vestiture, but is easily separated by the narrowly oblong calyx lobes verses the ovate lobes of *A. nigrescens*. *Ardisia verdisepala* also has affinities to *A. tuerkheimii*, because both have narrow calyx lobes; however, *A. verdisepala* is immediately separated from the virtually glabrous *A. tuerckheimii*, by the well-developed vestiture.

PARATYPES. **MEXICO. Chiapas:** Mpio. Ocosingo, 6–8 km N of Ocosingo along road to Bachajón, 900 m, 9 Nov 1971 (fl), *D. Breedlove & A. Smith 22120* (MO); *22121* (LL, MO, NY); 24 Sep 1972 (fl), *D. Shrubs to small trees 0.5–15 m tall, 2.5–25 cm in diam. **Branchlets** slender, terete, 1–3 mm in diam., very sparsely to densely puberulent of simple trichomes. **Leaves**: with leaf blades membranous, elliptic, 2.8–12.5 cm long, 0.9–5.8 cm wide, apically abruptly long acuminate, the acumen 0.5–2.2 cm long, basally obtuse, the midrib impressed above, prominently raised below, the secondary veins 14–30 pairs, prominulous above, prominently raised below, inconspicuously to conspicuously punctate and punctate-lineate, glabrous to scattered puberulent of simple trichomes on the upper and lower surface, especially along the midvein, the margins entire to crenate or serrate, flat; petiole slender, canaliculate, 0.5–1.1 cm long, glabrous. **Inflorescences** terminal, erect, pinnately paniculate, 1.5–12 cm long, 1.5–7 cm wide, shorter to slightly longer than the leaves, the rachis glabrous to densely puberulent of simple trichomes, the branches 4–9-flowered corymbs; peduncles nearly absent to 1 cm long, glabrous; inflorescence branch bracts caducous, membranous, oblong to obovate or oblanceolate, 3–9 mm long, 1–3 mm wide, apically acute, basally acute on sessile or short peti-

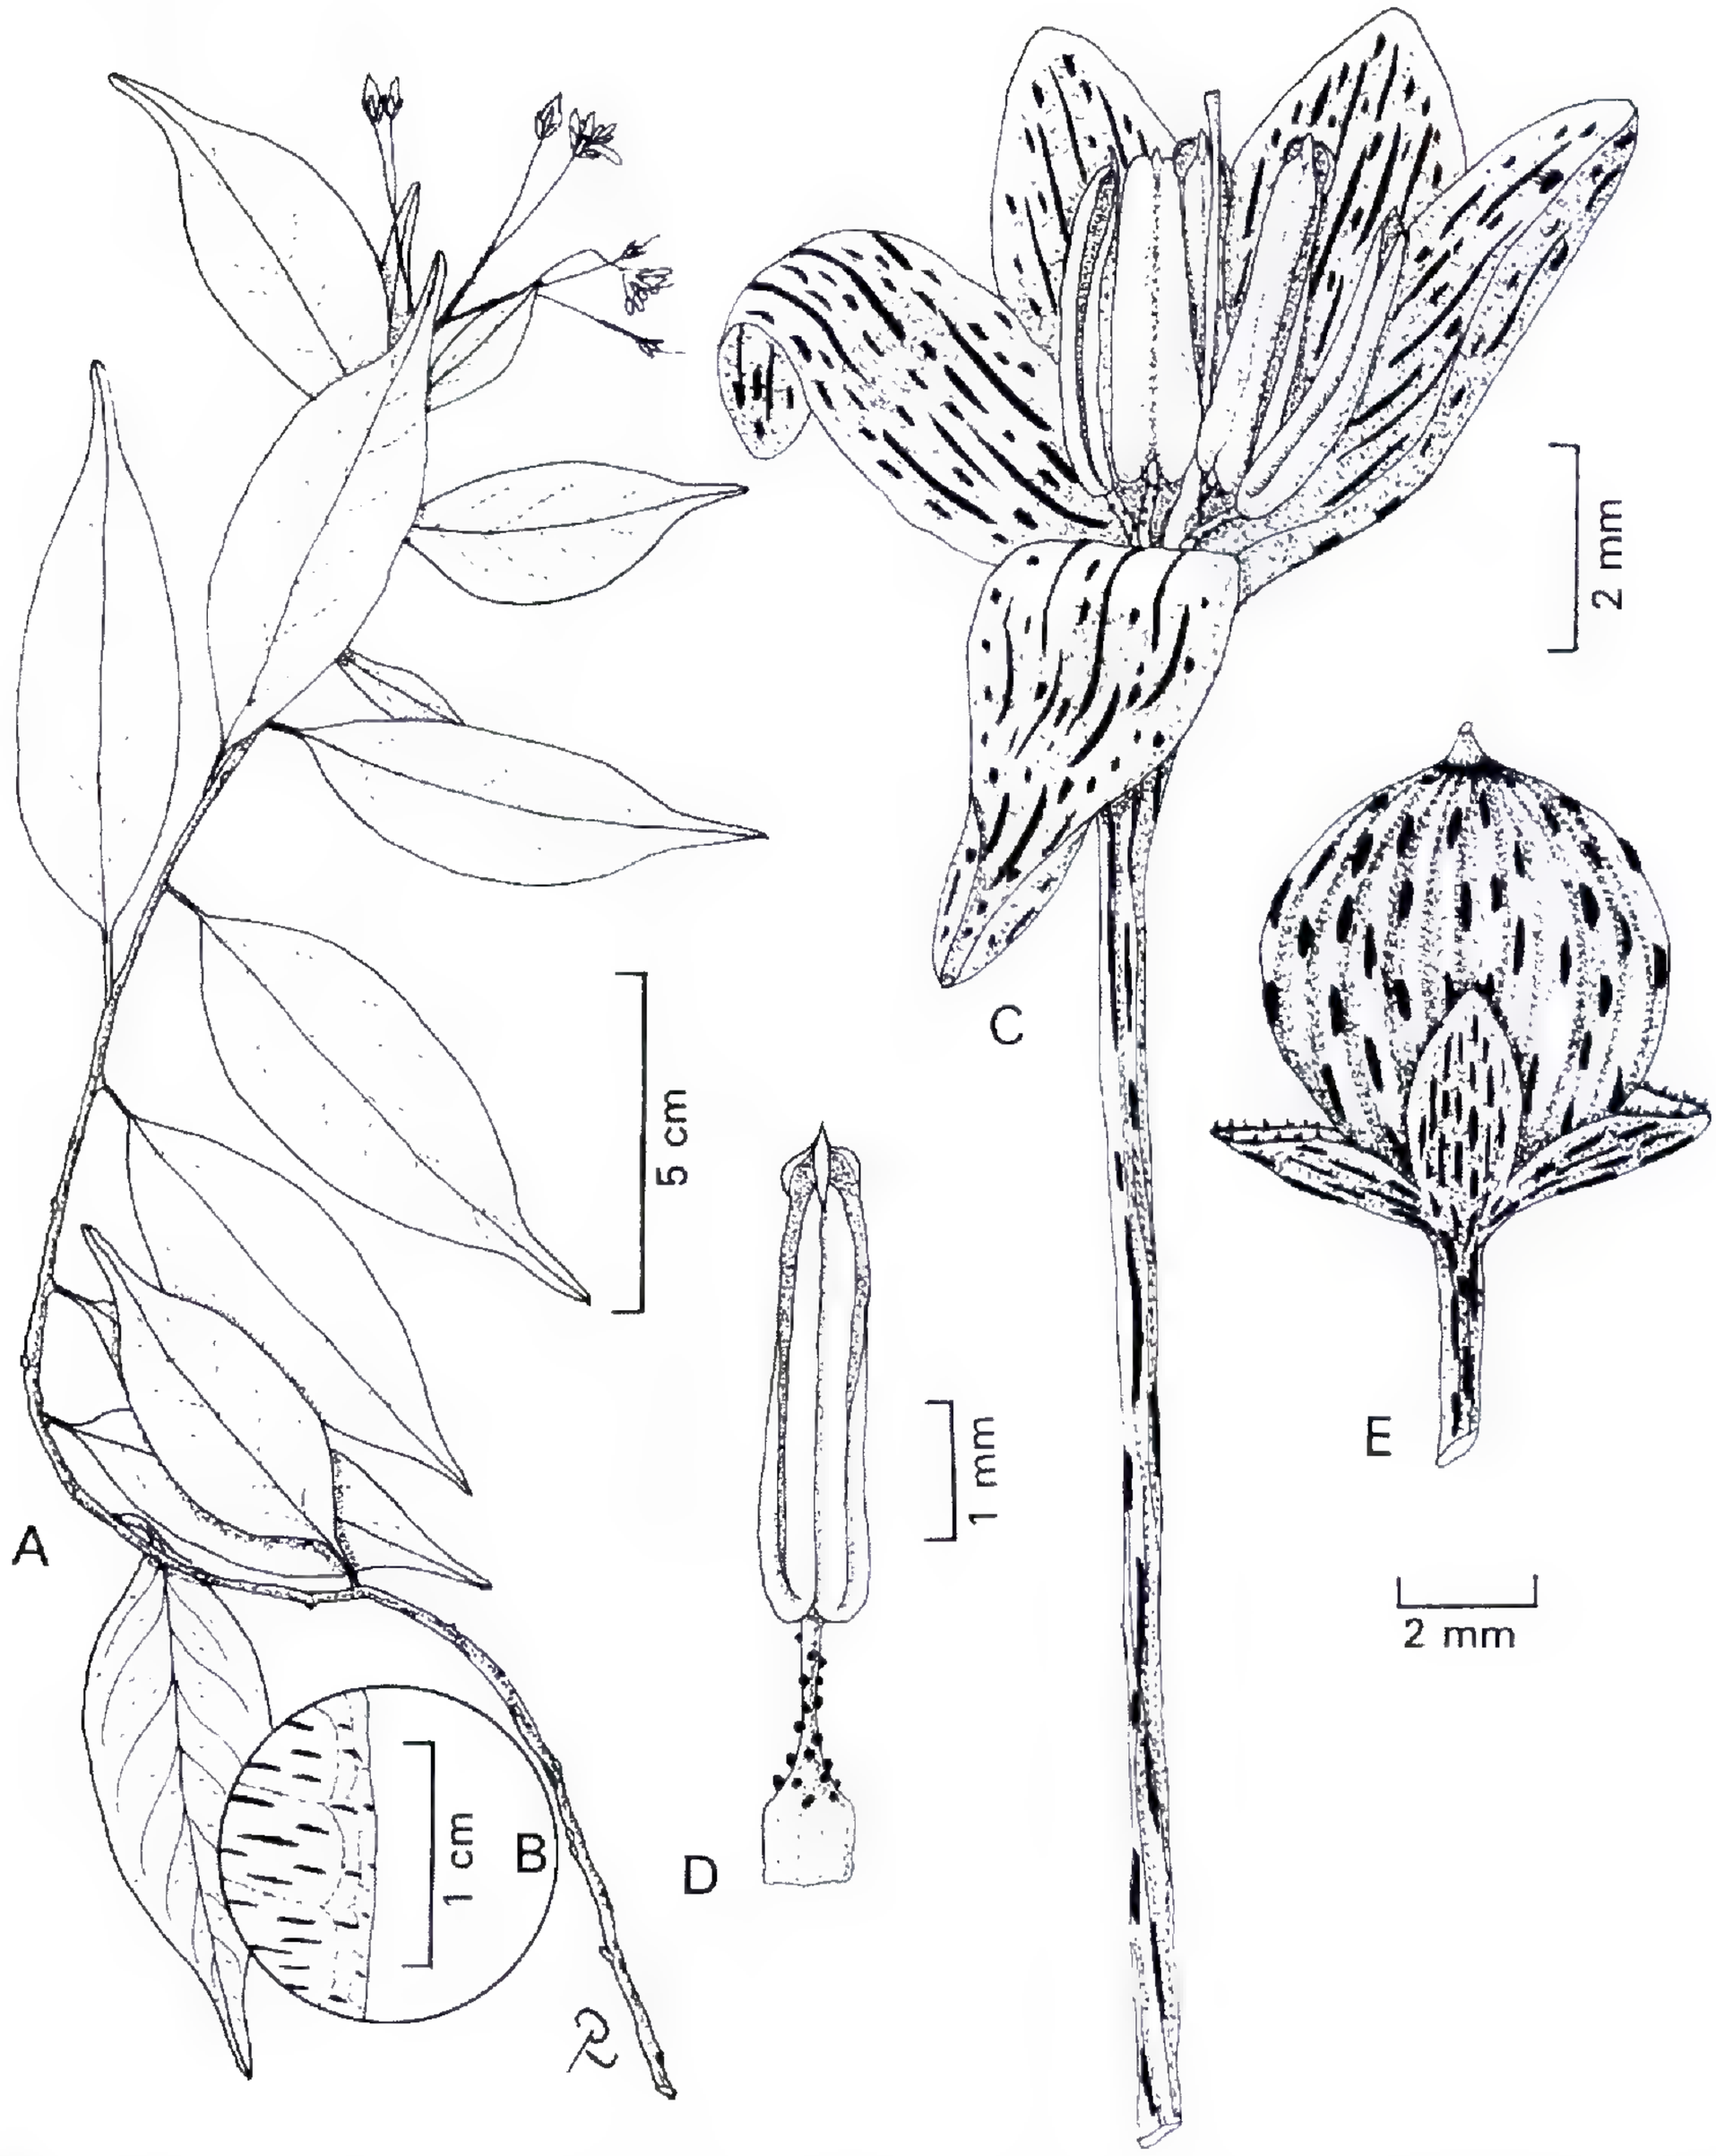

FIG. 4. *Ardisia tuerckheimii* Donn. Sm. **A.** Flowering branch. **B.** Detail of abaxial leaf surface. **C.** Flower. **D.** Stamen, showing adaxial surface. **E.** Fruit. A–D drawn from lectotype, *H. von Türckheim 1035* (US). E drawn from *E. Contreras 6668* (LL).

oles, the veins prominent, conspicuously and prominently punctate and punctate-lineate, glabrous, the margins entire; floral bracts apparently absent in the upper portion of the inflorescence with no apparent scars; pedicels slender, terete, 1.1–1.8 cm long, conspicuously and prominently punctate and punctate-lineate, glabrous to densely puberulent with simple trichomes. **Flowers** 5-

merous, white to pinkish; calyx lobes membranous, ovate to narrow oblong or oblanceolate, 1.5–3 mm long, 0.6–2 mm wide, apically acute to rounded, conspicuously and prominently punctate and punctate-lineate, glabrous to scattered papillae inside and out, the margins entire, scattered hirsute-ciliolate; corolla membranous, 4–10.2 mm long, the tube 0.7–1.9 mm long, the lobes oblong, 4.5–9.1 mm long, 1.6–5 mm wide, apically acute to rounded, conspicuously and prominently punctate and punctate-lineate, glabrous except rarely with a few yellow papillae at the base within, the margins entire, erose; stamens 4.7–6.2 mm long, the filaments 1.8–2.9 mm long, the staminal tube 0.2–0.9 mm long, the apically free portion 1.7–2.5 mm long, epunctate, with scattered yellow papillae near the base, the anthers free, lanceolate, 3.2–5.1 mm long, 0.6–1.6 mm wide, apically apiculate, basally subcordate, the connective inconspicuously punctate; pistil 5.2–8.3 mm long, glabrous, inconspicuously punctate, the ovary ovate, 0.8–1.5 mm long, the style 4.2–6.7 mm long, inconspicuously punctate and punctate-lineate, the ovules 8–15. **Fruit** globose, 5–6.4 mm long, inconspicuously punctate and punctate-lineate.

Distribution.—*Ardisia tuerckheimii* is known from southern Mexico (Oaxaca, Veracruz and Chiapas), southern Belize (Cayo and Toledo), northern Guatemala (Petén, Huehuetenango, Baja Verapaz, Alta Verapaz and Izabal) and northeastern Honduras (Cortés, Atlántida and Yoro). It grows from 800–1,500 m.

Ecology and conservation status.—*Ardisia tuerckheimii* occurs in primary and secondary, pine-oak-Liquidambar, lower montane and montane forests. This species appears to be quite common and not in any immediate danger.

Etymology.—This taxon was named in honor of the German-born collector Hans von Türckheim (1853–1920), who collected extensively in Guatemala and Santo Domingo.

In John Donnell Smith's (1888) original description he clearly based this taxon on the *H. von Türckheim 1035* collection, and it is agreed that his types are housed at the Smithsonian Institution (US). However, three specimens are housed at US with no indication as to which sheet is the holotype, thus necessitating the need to select a lectotype. One of these sheets US no. 1339941 was photographed by the Field Museum (F neg. no. 55673) and was de-accessioned and sent as a gift to C.L. Lundell (LL-TEX). The remaining two US sheets are of approximately equal value, one labeled as US no. 40099 and the other US as no. 1339942; the latter appears to have an original hand written label. Although C.L. Lundell labeled the US no. 40099 sheet as the "Type," he did not formally lectotypify the collection. Because the US no. 40099 sheet is of slightly better quality and has a lower accession number, making it more likely that John Donnell Smith used this material, at least in part, for his original description, we designate this sheet as the lectotype.

Ardisia tuerckheimii is an extremely variable species, which has led to its over description. Many of the collections from Mexico are glabrous or nearly so,

and gradually become more puberulent, as one moves south towards Honduras. However, because of this gradual gradation from glabrous to densely puberulent no clear justification can be found to recognize any of these proposed species and all are synonymized here. In fact the types of *Ardisia mitchellae* and *A. hirtella* were originally compared to *A. nigrescens* (including subsp. *donnellsmithii*), and not even compared to *A. tuerckheimii*, and separated based mostly on the differences in the indument, which is clearly different. *A. erythrocarpa* is unique only for its slightly larger fruits and slightly ciliated larger sepals. Populations of *A. brevipes* are unique only for their apparent subsessile fasciculate inflorescences with shorter peduncles, and with what are described as "bulbous" anther bases, and involuted petals apically. Populations of *A. carlsonae* are unique only for their slightly larger flowers, slightly smaller leaves and slightly obtuse anther. The type of *A. trinitariae* has slightly longer pedicels, slightly larger flowers, "bulbous" anthers bases and slightly oblong leaves. Finally, *A. tuxtepecana* differs slightly by its slender habit and smaller more densely puberulent leaves with slightly longer pedicels. Close examination of the total variation in this species shows that the slight differences, displayed by the synonymied taxa are not discontinous but fall within the range of variation of *A. tuerckheimii*.

Specimens examined. **MEXICO. Chiapas:** Mpio. La Trinitaria, slope at the Lago of Monte Bello, 25 mi E of La Trinitaria, 5,100 ft [1,554 m], 13 Apr 1965 (fr), *D. Tún O. 1479* (F, LL); Along road to Arroyo Dolores, ca 300 m S of Dolores, without elev., 16 Feb 1971 (fr), *R. Tún O. 1587* (F, LL); Dolores, without elev., 14 Feb 1971 (fr), *R. Tún O. 1563* (F, LL); Santa Elena, along road to La Libertad, km 9, SE side, without elev., 8 May 1971 (fr), *R. Tún O. 1753* (F, LL, MO); Poptún, along road to San Luís, km 117, ca 125 m W of road, without elev., 7 Jan 1972 (fr), *R. Tún O. 2158* (F, LL, MO, NY). **HONDURAS**. **Atlántida:** Mpio. Esparta, 19.2 km E of Tela on the Tela-Ceiba Hwy., ca. 1.5 km S of the hwy., near San Francisco de Soco, 15° 44' N, 087° 21' W, 50–100 m, 15 Apr 1994

(fl), *A. Brant & R. Zúniga 2842* (F, MEXU, MO); Along road for municipal water supple of Tela, Lancetilla Botanical Gardens, on road ca. 2 mi WSW of Tela and S of main hwy., 15° 44' N, 087° 27' W, 70–90 m, 9 Feb 1987 (fr), *T. Croat & D. Hannon 64596* (FTG, MO); Tela, Lancetilla Valley, valley above Experiment Station, along stream and slopes above stream but below the dam, 15° 43' 00" N, 087° 27' 30" W, 30–60 m, 4 Nov 1988 (fr), *J. MacDougal et al. 3159* (MO); Vicinity of Tela, 500 ft [152 m], 6 May 1926 (fl), *E. Mitchell 98* (GH); Lancetilla, 7 km SW de Tela, 150 m, 3 Feb 1986 (fr), *E. Mondragón 128* (MO); Vicinity of San Alejo, at base of hills S of San Alejo near Río San Alejo, 150–270 m, 22–27 Apr 1947 (fl), *P. Standley 7616* (F); Lancetilla Valley, near Tela, 20–600 m, 6 Dec 1927–20 Mar 1928 (fr), *P. Standley 52643* (A, F, US); *52983* (A, F, US); *53120* (A, F, US); *55598* (F); *56563* (A, F, US); *56803* (A, F, US); *56882* (F, GH, US). **Cortés:** Along Río Lindo near Carrizal, 550 m, 12 Apr 1951 (fl), *L. Williams & A. Molina R. 17804* (F, GH, US). **Yoro:** Río Texiguat watershed, 15° 30' 10" N, 087° 26' 32" W, 220 m, 18 Apr 1995 (fl), *T. Hawkins & M. Merello 767* (F, MEXU, MO, NY, TEX); Near Progreso, without elev., 26 Mar 1929 (fl), *W. Hottle 26* (F). **Unknown locality in Honduras:** Puerto Sierra, forest along Highland Creek, without elev., 18 Jan 1903 (fr), *P. Wilson 69* (NY, US).

ACKNOWLEDGMENTS

We thank the Missouri Botanical Garden and the Flora Mesoamericana Project, as well as the Fairchild Tropical Garden, for their support, to bring Ricketson and Pipoly together to work on the project. We gratefully acknowledge the loans from many herbaria that made the study possible, along with our collaborators who supplied us with much of the critical material. Richard G. Walter (formally of CS) and Gerrit Davidse (MO) generously gave of their time to provide thorough reviews of the entire manuscript. Special thanks are due to Roy Gereau for his critical review of the Latin diagnoses published herein. The drawings were prepared by Jon Ricketson. Finally, the assistance of Jon Ricketson's volunteer, Mary Bard, greatly facilitated the annotation and movement of specimens.

BOOK NOTICES

Systematics/Monographs/Floras/Guides

R.P. (Rod) Randall. 2002. **A Global Compendium of Weeds.** (ISBN 0-9587439-8-3, hbk.). R.G. and F.J. Richardson, P.O. Box 42, Meredith, Victoria 3333, Australia. (Orders: www.weedinfo.com.au, richardson@weedinfo.com.au, +61-3-5286-1533 fax, VISA, MasterCard, BankCard, AE, checks [Australian dollars only] payable to R.G. and F.J. Richardson). $A165.00 plus $A10 postage within Australia, overseas postage: please ask for a quote, 944 pp., almost 21,000 entries, 6 3/4 × 9 3/4".

From the backcover.—"Predicting which plants will become weeds is difficult, with the single most important indicator of a species' weed potential being a documented weedy history."

"Until now, the most comprehensive coverage of the world's weed flora was produced in 1979 and listed 6400 species. In this compendium, Rod Randall has compiled a list of almost 21,000 entries, as well as a comprehensive index containing more than 15,000 alternate scientific names and 27,000 common names in numerous languages."

"A *Global Compendium of Weeds* is specifically designed to give anyone interested in the weed potential of a plant a report on its status with, most importantly, further avenues of finding more information through extensive reference listing."

Having received a recent request for information on dragon grass or Chinese alpine rush (*Poa sphondylodes*), I checked the list and to my surprise found it listed. The entry came with eight references that presumably lead you to additional information. A couple of the references also include websites that I checked...two worked and one had already changed addresses. Not a surprise. The index is extensive and includes common and alternate names (synonyms). Table 1 is the source codes (references with the taxonomic and geographic entries) with references and includes 300 references. Table 2 is the source codes for each region represented in the book. This an impressive compilation.—*Barney Lipscomb, Botanical Research Institute of Texas, 509 Pecan St, Fort Worth, TX 76102-4060, U.S.A., barney@brit.org.*

Carmine Stahl and Rita McElvaney. 2003. **Trees of Texas: An Easy Guide to Leaf Identification.** (ISBN 1-58544-242-9, hbk.). Texas A&M University Press, John H. Lindsey Bldg., Lewis St. 4354 TAMU, College Station, TX 77843-4354, U.S.A. (Orders: wlawrence@tamu.edu, http://www.tamu.edu/upress, 800-826-8911). $29.95 hbk., 338 pp., 18 color, 270 b/w photos, 1 map, Bib., Index, 7 appendices, 8 1/2" × 11".

This book contains numerous life-sized leaf, flower, and fruit images. With more than 200 native and naturalized species organized by leaf shape, it leaves out a number of species. The genus *Crataegus* (hawthorn) has 25–30 species in Texas and Stahl and McElvaney cover nine species. Three species of *Prunus* are cover and yet there are a dozen or more in the state. Nothing is wrong here but one needs to keep in mind that *Trees of Texas: An Easy Guide to Leaf Identification* is a guide to the more common trees of Texas; a very nice one at that with photographs that are sharp and crisp with detail. —*Barney Lipscomb, Botanical Research Institute of Texas, 509 Pecan St, Fort Worth, TX 76102-4060, U.S.A., barney@brit.org.*

A REVISION OF THE *PSIDIUM SALUTARE* COMPLEX (MYRTACEAE)

Tempe, AZ 85287-4501, U.S.A.
les.landrum@asu.edu

ABSTRACT

The *Psidium salutare* complex is revised with keys, descriptions, maps, and illustrations and is considered to consist of *P. laruotteanum* (with no additional subspecific taxa) and *P. salutare* (with a total of five varieties). This complex ranges from eastern temperate South America to Mexico and Central America. The following taxa are lectotypified: *Calycolpus parviflorus* Sagot, *Myrtus acutata* O. Berg, *Myrtus blanchetiana* O. Berg, *Myrtus cuspidata* O. Berg, *Myrtus cuspidata* var. *tetramera* O. Berg, *Myrtus incana* O. Berg, *Myrtus mucronata* Cambess., *Myrtus nivea* O. Berg, *Myrtus pubescens* O. Berg, *Myrtus rigida* O. Berg, *Myrtus sellowiana* O. Berg, *Myrtus sericea* var. *fruticosa* O. Berg, *Myrtus suffruticosa* O. Berg, *Myrtus suffruticosa* var. *latifolia* O. Berg, *Psidium guayabita* A. Rich., *Psidium pohlianum* O. Berg, *Psidium salutare* var. *laxum* O. Berg and *Psidium salutare* var. *subalternum* O. Berg. The following new combinations are made: *Psidium salutare* var. *decussatum* (DC.) Landrum, *Psidium salutare* var. *mucronatum* (Cambess.) Landrum, *Psidium salutare* var. *pohlianum* (O. Berg) Landrum, and *Psidium salutare* var. *sericeum* (Cambess.) Landrum.

RESUMEN

Se hace una revisión del complejo de *Psidium salutare* con claves, descripciones, mapas, e ilustraciones. El complejo incluye *P. laruotteanum* (sin taxa subspecíficos adicionales) y *P. salutare* (con un total de cinco variedades). Este complejo se encuentra desde el este de Sur América templada hasta México y Centro América. Se seleccionan lectotipos para los siguientes taxa: *Calycolpus parviflorus* Sagot, *Myrtus acutata* O. Berg, *Myrtus blanchetiana* O. Berg, *Myrtus cuspidata* O. Berg, *Myrtus cuspidata* var. *tetramera* O. Berg, *Myrtus incana* O. Berg, *Myrtus mucronata* Cambess., *Myrtus nivea* O. Berg, *Myrtus pubescens* O. Berg, *Myrtus rigida* O. Berg, *Myrtus sellowiana* O. Berg, *Myrtus sericea* var. *fruticosa* O. Berg, *Myrtus suffruticosa* O. Berg, *Myrtus suffruticosa* var. *latifolia* O. Berg, *Psidium guayabita* A. Rich., *Psidium pohlianum* O. Berg, *Psidium salutare* var. *laxum* O. Berg y *Psidium salutare* var. *subalternum* O. Berg. Se hacen las siguientes combinaciones nuevas: *Psidium salutare* var. *decussatum* (DC.) Landrum, *Psidium salutare* var. *mucronatum* (Cambess.) Landrum, *Psidium salutare* var. *pohlianum* (O. Berg) Landrum, y *Psidium salutare* var. *sericeum* (Cambess.) Landrum.

Psidium (Myrtaceae) is a genus of at least 50 and perhaps as many as 100 species (McVaugh 1968) with a natural range from Mexico and the Caribbean to Uruguay and northern Argentina on the American continents and extending to some east Pacific islands (e.g. Galapagos). A few weedy and/or cultivated species have been spread by humans around the World to tropical and subtropical climates (e.g., *P. guajava* L., *P. cattleianum* Sabine). The great variance in estimates of numbers of species is due to complexes of entities that might themselves be considered single variable species or species groups. One such group is the

SIDA 20(4): 1449–1469. 2003

Psidium salutare is complex, which ranges from Mexico to Uruguay and includes such commonly accepted species as *P. laruotteanum, P. salutare, P. luridum, P. incanum,* and *P. pohlianum.* The purpose of this paper is to treat the *P. salutare* complex, as it may be several years before a monograph of the whole genus will be completed.

Psidium is distinguished from other genera by a combination of floral and seed characters discussed in Landrum and Sharp (1989), namely, flowers 5-merous with multiovulate locules; placenta often peltate; seed coat rough or dull, not lustrous, covered with a pulpy layer when wet; hard portion of seed coat (5–)8–30 cells thick at narrowest point, the cells thick-walled, elongate, overlapping. The *P. salutare* complex is differentiated from other species of the genus by 1) a usual habit of subshrub or shrub (but reaching tree size in some populations); 2) a habitat mainly of grasslands or low shrubby growth (cerrado) that is frequently burned; 3) an ability to sprout back from underground stems even after fires; 4) leaves with brochidodromous venation with a well marked marginal vein that closely follows the margin and tertiary veins that form a reticulate-dendritic pattern; 5) relatively small flower buds (4–9 mm) with the calyx open; and 6) a peltate placenta with one or two rows of ovules on the edge of the each lamina.

Another group of similar range (northern Argentina to Venezuela), habit, and habitat is the *Psidium cinereum* complex (*P. cinerum* DC., *P. grandifolium* DC., *P. australe* Cambess., *P. missionum* D. Legrand, and *P. suffruticosum* O. Berg). That complex differs in having leaves with brochidodromous venation (sometimes blending into acrodromous venation proximally) with a marginal vein that broadly arches between the laterals and thus does not closely follow the margin, relatively large flower buds (often over 1 cm long) with the calyx open or closed, and a non-peltate, only slightly protruding placenta with numerous irregular rows of ovules.

A third group that is sometimes confused with the *P. salutare* complex is the *P. oligosperma* DC. complex, which includes *P. sartorianum* (O. Berg) Nied. It differs in having the calyx closed or nearly closed and being shrubs to relatively large trees of woodland or forest habitats.

The great variability in the *Psidium salutare* complex is reflected in the numerous names that have been proposed, including at least 44 basionyms at the specific level and several more subspecific names. After several years of intermittent study of herbarium specimens and fieldwork I have concluded that the *P. salutare* complex is best considered two species: *P. salutare* and *P. laruotteanum.* I recognize *P. salutare* as containing five varieties that correspond closely with geographic regions that sometimes overlap. All the varieties recognized here have been recognized previously as species by other taxonomists, e.g., Berg (1857–1859), de Candolle (1828), Legrand and Klein (1977), and Rotman (1976). Because I often find specimens that are intermediate between the enti-

ties I recognize as varieties of *P. salutare*, I suspect that they freely interbreed when growing sympatrically. I strongly recommend accepting them at the varietal level but realize others may disagree. Thus, in the discussion of the nontypical varieties I indicate the name that the entity would have if recognized at the specific level.

For illustrations I have used portions of scanned herbarium specimens. These images can be viewed in their entirety in color in the Image Library on the ASU Herbarium website http://lifesciences.asu.edu/herbarium/. A list of exsiccatae will also be made available at the same website once this paper is published.

Ecology.—The species of *Psidium salutare* complex are similar in ecological preferences and often grow side by side (e.g., near Brasilia, Brazil). Both grow in fire-induced savannas or scrub vegetation (cerrado). Both sprout back from underground stems after fire or other disturbance. The climates in which they grow often have distinct dry and wet seasons, with freezing temperatures being rare or non-existent. Commonly associated with them are other genera of Myrtaceae, e.g., *Campomanesia*, *Eugenia*, and *Myrcia* and the vegetation is often dominated by Poaceae, Fabaceae, and Asteraceae.

KEY TO THE SPECIES AND VARIETIES OF THE *P. SALUTARE* COMPLEX

1. Young leaves densely covered with hairs beneath, the lower surface of the leaf often hidden.
   2. Leaves silvery lanate, usually less that 1.5 cm wide; apex usually sharply acute to abruptly acuminate; hairs of leaves of two lengths, short and tangled and long and nearly straight; Argentina, Uruguay, Bolivia, Paraguay, Rio Grande do Sul (Brazil). _____ **P. salutare** var. **sericeum**
   2. Leaves yellowish to grayish short tomentose, often over 1.5 cm wide; apex acute to rounded; hairs of leaves uniform in length, all tangled; Paraguay, Bolivia, Paraná (Brazil), north to Venezuela and Costa Rica. _____ **P. laruotteanum**
1. Young leaves glabrous to moderately pubescent beneath.
   3. Venation clearly evident above and below, the marginal vein within 1 mm of the margin; leaves often narrowly elliptic or lanceolate, often 3 or more times as long as wide, often lustrous; leaf apex often apiculate; calyx lobes longer than calyx tube plus hypanthial tube; Argentina, Uruguay, Paraguay, Rio Grande do Sul, Santa Catarina, Paraná. _____ **P. salutare** var. **mucronatum**
   3. Venation clear y evident or not, the marginal vein usually more than 1 mm from the margin; leaves mostly less than 3 times as long as wide, lustrous or not; leaf apex usually without an apiculum; calyx-lobes longer or shorter than calyx tube plus hypanthial tube.
      4. Leaves narrowly elliptic to elliptic, mostly less than 1.5 cm wide, the apex usually rounded; peduncle 0.5–1.5 cm long; Paraná to Goiás. _____ **Psidium salutare** var. **decussatum**
      4. Leaves various, often lanceolate, usually over 2 cm wide, the apex often acute; peduncle 0.4–3 cm long; Paraguay to Mexico and Caribbean.
         5. Leaves 4–9 cm long, 2–5 cm wide, elliptic to obovate; usually shrubs to small trees; plants glabrous; central Brazil, Bolivia to Venezuela. _____ **Psidium salutare** var. **pohlianum**

5. Leaves 3.3–7 cm long, 1–3.3 cm wide, usually lanceolate, ovate, or elliptic; normally subshrubs; plants glabrous or pubescent; Paraguay to Mexico and Caribbean. _____ **Psidium salutare** var. **salutare**

Psidium laruotteanum Cambess., in Saint-Hilaire Bras. merid. 2:282. 1833. (**Figs. 1, 3**). TYPE: BRAZIL: "Prope Alto da Varginha (prov. Minas Geraes)," *Saint-Hilaire s.n.* (HOLOTYPE: P!, = F-36412!, = ASU photo!).

Psidium quinquedentatum Amshoff, Recueil Trav. Bot. Neer. 39:164. 1942 TYPE: SURINAM: "Upper Sipaliwini R. near Brazilian frontier," *Rombouts, H. E. 329* (HOLOTYPE: U; ISOTYPES, MO!, NY!).

Shrub up to ca. 1.5 m high, often less than 0.5 m high, with new shoots arising from a woody subterranean base or rhizome, densely tomentose to sparsely pubescent over most surfaces; hairs to ca. 1.5 mm long, grayish, yellowish-white, to rusty, usually curled and tangled; young twigs usually densely tomentose, remaining so for more than 1 year, the bark of older twigs becoming rough and scaly. **Leaves** normally opposite (rarely in whorls of 3, or spirally arranged) obovate, oblanceolate, elliptic, or oblong, 3–9 (–11) cm long, 1.6–4.5(–6) cm wide, 1.6–3.2 times as long as wide; apex rounded, acute, or acuminate; base obtuse to cuneate; petiole 0–2 mm long, ca. 2 mm wide, tomentose; midvein flat or slightly raised above, prominent below, usually more densely hairy above than surrounding blade, the venation brochidodromous with 7–13 pairs of lateral veins, these weak to prominent, slightly raised above in mature leaves, ascending at an angle

FIG. 1. *Psidium laruotteanum*. **A,** *Ribas & Pereira 1812* (ASU), young branch of 0.7 m shrub; note large leaves. **B & C,** *Hatschbach 53638* (ASU). **B,** middle portion showing full stature of plant with new growth arising from ground level stem; **C,** close view of flowers.

of ca. 45 degrees, nearly straight, joining an equally prominent, shallowly arcing marginal vein near (1–2 mm) the margin, the tertiary veins weaker, alternating with the laterals, branching, arising from the marginal vein; blades stiffly coriaceaous at maturity, drying gray-green to reddish-brown (under hairs), the lower surface usually densely tomentose, the upper surface usually sparsely to moderately pubescent. **Flower bud** ovoid to pyriform, 4–9 mm long; peduncles solitary in the axils of leaves or bracts, 0.2–3 cm long, 1–1.5 mm wide, normally uniflorous (rarely triflorous), densely pubescent; bracteoles linear to narrowly elliptic, 5–8 mm long, 1–1.5 mm wide, densely pubescent, caducous at about

anthesis; calyx open, prolonged ca. 1 mm beyond the ovary summit, the lobes about triangular, 1–4 mm long, 1–3 mm wide, densely pubescent within and without, sometimes less pubescent than the hypanthium; petals suborbicular to obovate, 8–10 mm long, subglabrous; hypanthium funnel-shaped, 2–5 mm long, densely tomentose; disk ca. 4 mm across; stamens 70–200, 5–9 mm long; anthers suborbicular, 0.5–1 mm long; style 6–8 mm long; ovary (2–)3(–4)-locular; ovules 7–19 per locule, reflexed, usually uniseriate on the margin of a peltate placenta. **Fruit** subglobose, 1.2–2 cm long; seeds 5–20, more or less rounded, 4–7 mm long.

VENEZUELA. Bolivar: Santa Elena de Uairén, 2–4 Mar 1972 (fl), *Bunting & Holmquist 4764* (NY); Roscio, ca. 3 km NW de San Ignacio de Yuruani (5°01'N, 61°8'W), 900 m, 20 Jun 1983 (fr), *Huber & Alarcon 7512* (MO, NY, VEN). **Zulia:** Sierra de Perijá, above Pishikakao, 400–1850 m, 1–3 Apr 1972 (fl), *Steyermark et al. 105766* (MICH).

Psidium rufum DC. (= *P. widgrenianum* O. Berg), which ranges from Paraná to Goiás and Bahia, is sometimes confused with *P. laruotteanum*. They are contrasted in the key below.

1. Shrub usually no more than 1.5 m high; hairs grayish, yellowish, or reddish brown, usually curled and tangled, obscuring the lower leaf surface; midvein and lateral veins flat or slightly raised above; petiole 0–2(–3) mm long; calyx lobes triangular or subtriangular, 1–4 mm long. ____ **P. laruotteanum**

1. Shrub or tree to 8 m high; hairs mainly reddish brown, mostly erect, usually not obscuring the lower leaf surface; midvein and often lateral veins impressed above; petiole (2–)3–9 mm long; calyx-lobes mainly broadly rounded, 0.5–2 mm long (rarely triangular and up to 4 mm long). ____ **P. rufum**

Psidium laruotteanum is variable as to leaf size and shape (Fig. 1). Smaller plants, especially new sprouts, tend to have small elliptic leaves and larger plants tend to have large oblanceolate or obovate leaves. Since a similar pattern is seen throughout the range, I do not suspect a genetic basis for this difference.

Berg cites the type of *Psidium aerugineum* var. *angustifolium* as being at LE but cites no collector or locality. A specimen at LE, collected by Sellow, annotated by Berg as *Psidium aerugineum*, I considered to be an isotype of that taxon. I suspect that this same specimen is the holotype of *Psidium aerugineum* var. *angustifolium*, but it was never annotated by Berg as such. It has relatively narrow young leaves, which Berg mentions in the protologue of var. *angustifolium*. I have found two other cases where Berg described a taxon at LE but seems not to have annotated a specimen (*Psidium riedelianum* O. Berg, in Mart., Fl. bras. 14(1):602. 1859) and *P. pohlianum* var. *brevipes* discussed below under *P. salutare* var. *pohlianum*.

Psidium salutare (H.B.K.) O. Berg, Linnaea 27:356. 1856. *Myrtus salutaris* H.B.K., Nov. gen. sp. 6:132. 1823. TYPE: "Carichanam, ad ripam Orinoci," *Humboldt & Bonpland s.n.* (HOLOTYPE: P, = F-36905!; ISOTYPE: B, =B1263/11 photo at MICH!).

Subshrub or shrub up to ca. 1.5 m high (often less than 0.5 m high), with new shoots arising from a woody subterranean base or rhizome, with shoots often short lived, or in one variety sometimes reaching tree size (up to 10 m high), glabrous, glabrous except for disk and calyx-lobes within, or sparsely to mod-

erately pubescent on young growth, or silvery lanate in one variety; hairs when present whitish, 0.3–1 mm long; young twigs glabrous to densely pubescent, reddish-brown, becoming grayish, the older bark gray to reddish-brown, becoming flaky. **Leaves** opposite or alternate on some shoots (rarely ternate), ovate, lanceolate, elliptic, narrowly elliptic, obovate, oblanceolate, (1–)2–9 cm long, 0.6–5.5 cm wide, 1.4–5 times as long as wide, the margin entire to somewhat revolute; apex obtuse, acute to acuminate, abruptly acuminate, sometimes apiculate; base cuneate, obtuse, or rounded; petiole 0–2 mm long, 1–1.5(–2) mm wide; midvein normally flat or slightly raised above, prominent below, the venation brochidodromous, with 5–12 pairs of lateral veins, these prominent to scarcely visible, leaving the midvein at an angle of ca. 45 degrees or less, nearly straight, joining a clear shallowly arcing, equally prominent marginal vein near (0.2–2 mm) the margin, the tertiary veins forming a dendritic pattern between the laterals; blades stiffly coriaceous at maturity, drying reddish-brown to gray-green, dull or lustrous above, the cellular pattern sometimes visible with a dissecting scope. **Flower buds** pyriform, 4–7 mm long; peduncles, axillary, uniflorous or triflorous, 0.4–3.5 cm long, 0.5–0.8 mm wide; bracteoles linear to lanceolate, deciduous or persisting, 2–9 mm long, 0.5–2 mm wide; calyx open, cup-like, tearing ca. 1 mm between the lobes at anthesis, the lobes broadly rounded to ovate-triangular, 0.5–5(–6) mm long, 2–3 mm wide, glabrous to lanate without, usually puberulent (less often glabrous) within; petals obovate to suborbicular, 5–11 mm long; hypanthium obconic to campanulate, 2–4 mm long, extended beyond the ovary summit ca. 1 mm; disk 3–4 mm across, puberulent or glabrous; stamens 100–200, 5–12 mm long; anthers subglobose to oblong, 0.3–0.8 mm long; style 5–8 mm long; ovary 2–3-locular; ovules 9–48 per locule, uniseriate or biseriate along edge of the placenta, this strongly to scarcely peltate. **Fruit** globose to subglobose, 8–10 mm in diam.; seeds 4–20, 4–8 mm long, subovoide.

Psidium salutare is a widespread and variable species. There are a few recognizable forms that correspond to geographic regions that I recognize as varieties, but the limits between these varieties are often unclear. Legrand and Klein (1977, p. 723) also noted difficulty in distinguishing these entities, but chose to retain them at the specific level. One might speculate that these morphological types represent adaptive syndromes of characters for somewhat different niches. In-depth studies of the entities, including population samples, field studies, estimates of genetic distinctness and exchange, and transplant experiments should prove interesting in the future, especially for sympatric varieties, e.g., var. *sericeum* and var. *mucronatum*, or var. *decussatum* and var. *pohlianum*. As recognized here, there is still considerable variation in var. *salutare* to which specimens unassignable to any of the other varieties are tentatively placed.

Psidium salutare var. **salutare**

Psidium salutare (HBK) O. Berg, Linnaea 27:356, as to type. 1856. (**Figs. 2E, 4, 5**).

Myrtus arayan HBK, Nov. gen. sp. 6:133. 1823. TYPE: PERU [ECUADOR]: "prope Gonzanamam Peruvianorum, ad ripam fluminis Catamayo," *Humboldt & Bonpland s.n.* (HOLOTYPE: P,= F-36874!).

Psidium ciliatum Benth., in Hook. J. bot. 2:318. 1840. TYPE: BRITISH GUIANA: "dry savannahs," *Schomburgk s.n.* (HOLOTYPE: K; ISOTYPES [*Schomburgk 365*], P!, = ASU photo!, W, = F-31434!).

Eugenia guayavillo Benth., Plantas Hartwegianas, 174. 1845. TYPE: MEXICO: "Popayan," *Hartweg 977* (HOLOTYPE: K, = ASU photo!).

Psidium guayabita A. Rich., Ess. Fl. Cub. 581. 1846. TYPE: CUBA: "Vuelta de Abajo," *J. M. Valenzuela s.n.*, (2 sheets at P!, ["TYPE" LECTOTYPE, here designated], = ASU photo!).

Psidium salutare var. *subalternum* O. Berg, Linnaea 27:357. 1856. TYPE: BRITISH GUIANA: "ad flumen Tacutu," *Rich. Schomburgk 498 & 1252; Rob. S. 365* (SYNTYPES B, lost; ISOSYNTYPES [*Schomburgk 365*], P! [LECTOTYPE, here designated], W, = F-31434!, = ASU photo!).

Psidium oerstedeanum O. Berg, Linnaea 27:360. 1856. TYPE: COSTA RICA & GUATEMALA: "Provincia Guanacaste (Oersted) & Rincón in Guatemala (Friedrichsthal)," *Oersted s.n. & Friedrichsthal 1226* (SYNTYPES W and "hb Oersted. no16"; SYNTYPE: C [*Oersted 4004*], = F-50931!).

Psidium salutare var. *laxum* O. Berg, Linnaea 27:357. 1856. TYPE: VENEZUELA: "Orinoco, ad Upata," *Otto 987* (HOLOTYPE: B, lost; ISOTYPE: LE [LECTOTYPE, here designated], = ASU photo!; possible ISOTYPE: W = F-31435!).

Psidium salutare var. *stricta* O. Berg, Linnaea 27:356. 1856. Inadmissible name to be replaced by *P. salutare* var. *salutare*.

Myrtus rigida O. Berg, in Mart., Fl. bras. 14(1):417 1857. TYPE: BRAZIL: "ad Paranapitanga distr. Itapeva in prov. S. Pauli," *Sellow s.n.* (HOLOTYPE: B, lost; ISOTYPE: P! [LECTOTYPE, here designated], = F-36443!, ASU photo!).

Myrtus blanchetiana O. Berg, in Mart. Fl. bras. 14(1):418. 1857. TYPE: BRAZIL: "Bahia," *Blanchet 3310* (HOLOTYPE: B, lost; ISOTYPES, W, G = F-23481!, P! [LECTOTYPE, here designated], = ASU photo!).

Myrtus sagraea O. Berg, Linnaea 30:710. 1860. TYPE: CUBA: without locality, *De la Sagra s.n.* (HOLOTYPE: P!, =ASU photo!).

Psidium lanceolatum O. Berg, Linnaea 30:704. 1861. TYPE: BRAZIL: without locality, (HOLOTYPE: P!, = ASU photo!).

Psidium guayabita var. *oblongata* Griseb., Cat. pl. Cub. 91. 1866. TYPE: CUBA: without locality, *Wright 2436* (HOLOTYPE: GOET; ISOTYPES, MICH!, MO!, NY!, = ASU photo!, P!).

Psidium guayabita var. *angustifolia* Griseb., Cat. pl. Cub. 91. 1866. TYPE: CUBA: without locality, *Wright 2436a* (HOLOTYPE: GOET).

Calycolpus parviflorus Sagot, Ann. Sci. Nat. (Paris) VI. 20:181. 1885. TYPE: FRENCH GUIANA: without locality, *Leprieur s.n.* (HOLOTYPE: P!, 2 specimens, ["TYPE" LECTOTYPE, here designated], = ASU photo!).

Psidium deltosepalum Barb. Rodr. ex Chodat & Hassl., Bull. Herb. Boissier 7:799. 1907. TYPE: PARAGUAY: "pr. Vaqueria Capibary," *Hassler 4400* (HOLOTYPE: G!, 3 specimens, =ASU photos!; ISOTYPES, NY!, P!).

Psidium valenzuelense Barb. Rodr. ex Chodat & Hassl., Bull. Herb. Boissier 7:798. 1907. TYPE: PARAGUAY: "pr. Valenzuela," *Hassler 6947* (HOLOTYPE: G!, 2 specimens; ISOTYPE: NY!).

Psidium arayan (HBK) Burret, Notizbl. Bot. Gart. Berlin-Dahlem 15:484. 1941.

Psidium gentlei Lundell, Amer. Mid. Nat. 29 483. 1943. TYPE: BELIZE: TOLEDO DIST.: "Monkey River, Jenkins Creek," 1 Aug 1942 (fr), *Gentle 4062* (HOLOTYPE: MICH!; ISOTYPES MO!, NY!).

Myrcianthes reptans D. Legrand, Bol. Univ. Paraná Fac. Farm. 27:1–3. 1971. TYPE: BRAZIL: Paraná, "Mun. Palmeira, Faz. S. Amelia," *Hatschbach 17697* (HOLOTYPE: MVM; ISOTYPE: HB!, =ASU photo!).

FIG. 2. *Psidium salutare*, branchlets with leaves and flowers or young fruits. **A,** *Irwin et al. 10699* (NY), var. *decussatum*. **B,** *Landrum 3856* (NY), var. *mucronatum*. **C,** *Irwin et al. 9101* (NY), var. *pohlianum*. **D,** *Venturi 7582* (F), var. *sericeum*. **E,** *Burch 6180* (NY), var. *salutare*.

Usually a subshrub less than 0.5 m high; leaves elliptic, lanceolate, oblanceolate, ovate, or obovate, 3–7 cm long, 1–3.3 cm wide, 1.6–3.2 times as long as wide, glabrous to moderately pubescent; venation obscure to moderately pronounced, the marginal vein usually about 1 mm from margin; apex usually without an apiculum; peduncle 1–5 cm long, uniflorous or triflorous; calyx-lobes shorter or longer than the hypanthial tube plus calyx tube, acute to rounded.

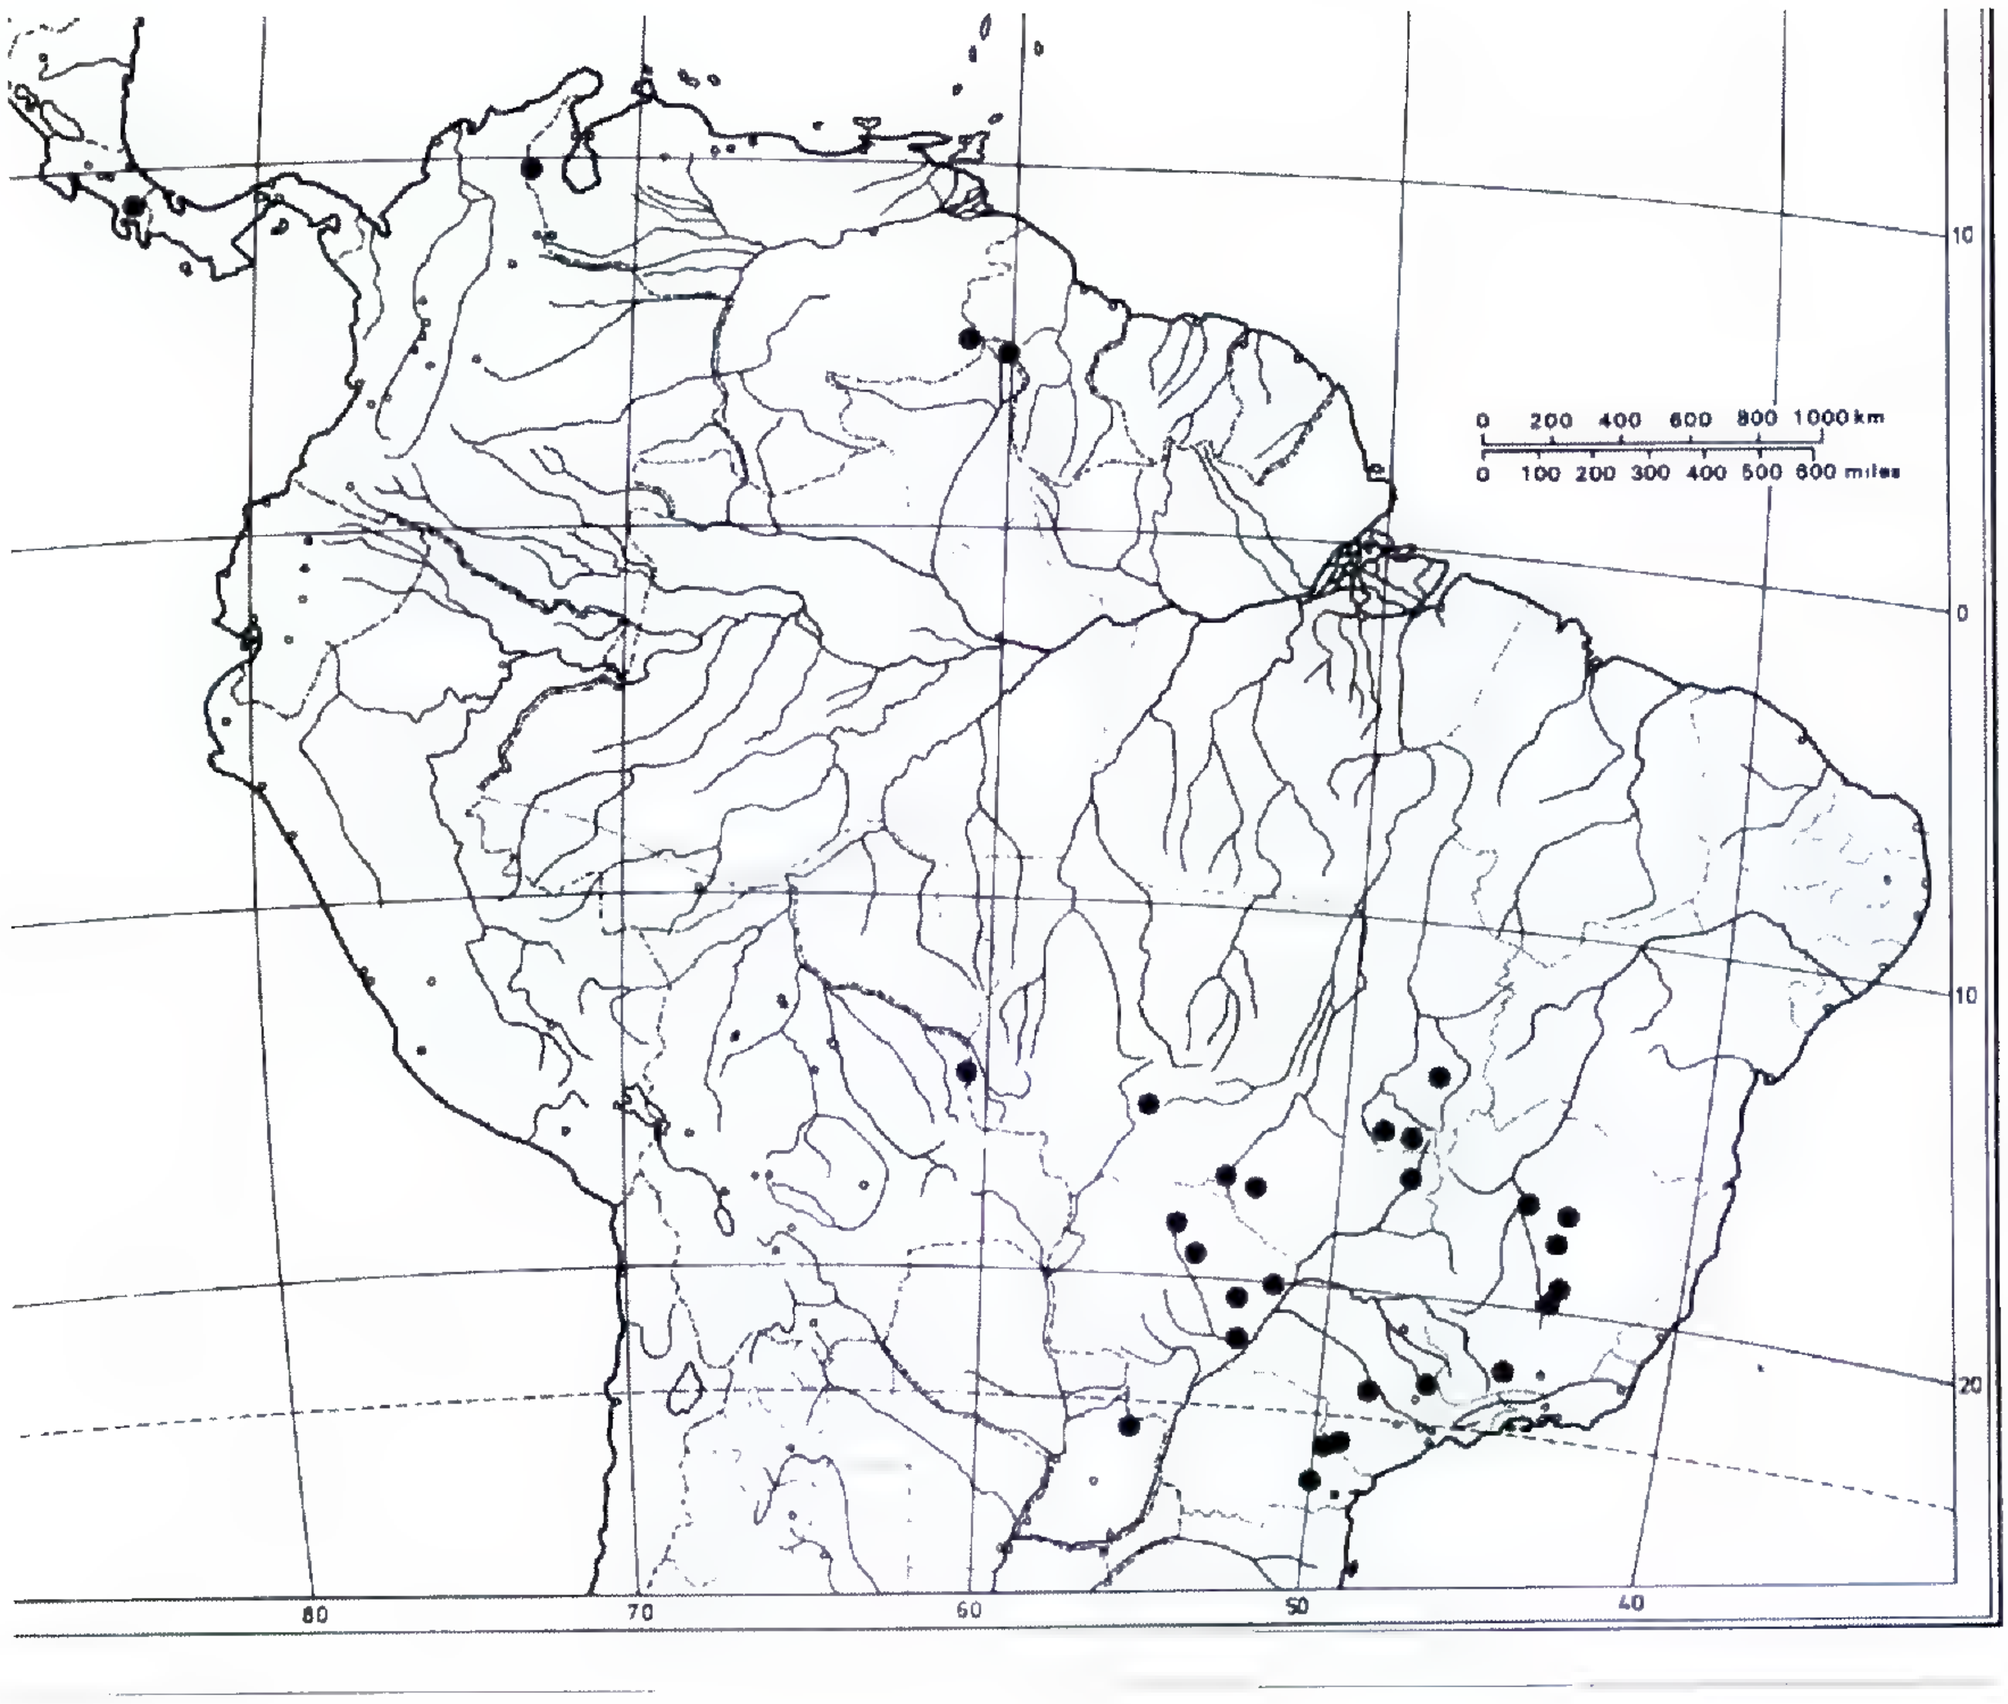

FIG. 3. Distribution of *Psidium laruotteanum*.

Representative specimens. **BELIZE. El Cayo:** Mountain Pine Ridge, San Agustin, Jul -Aug 1936 (fr), *Lundell 6560* (MICH, MO, NY); upper 200 m of Baldy Beacon, ca. 1000 m, 10 Jul 1970 (fr), *Spellman 1647* (MO).

BOLIVIA. Santa Cruz: P. N. Noel Kempff Mercado, Los Fierros (14°36'20"S, 60°51'30"W), 200 m, 26 Oct 1993 (fr), *Killeen et al. 5943* (ASU); P. N. Noel Kempff Mercado, 6 km NE del campamento Las Gamas (13°53'41"S, 60°48'46"W), 850 m, 28 Oct 1995 (fl), *Rodriguez & Surubí 549* (ASU).

BRAZIL. Ceará: Chapada do Araripe, ca. 15 km SW of Crato on BR-122 (7°30'S, 39°35'W), 860 m, 9 Jan 1983 (fl), *Plowman & Tavares Cacula 12704* (F). **Distrito Federal:** margem do lago Paranoa, 9 Nov 1978 (fr), *Heringer 701* (NY). **Goiás:** Corubaiba, Rio Corumba, Foz do Corrego (17°48'S, 48°21'W), 21 Sep 1993 (fl), *Da Silva et al. 1880* (SP); Serra do Caiapó, 35 km S of Caiaponia on road to Jatai (17°12'S, 51°47'W), 800–1000 m, 29 Oct 1964 (fl), *Irwin et al. 7552* (CAS); Serra dos Cristais, ca. 10 km W of Cristalina (17'S, 48'W), 1200 m, 4 Mar 1966 (fr), *Irwin et al. 13449* (MICH, MO, NY). **Mato Grosso:** Barra do Garças, 210 km along new road NNE of village of Xavantina, Corrego do Gato, ca. 450 m, 4 Oct 1968 (fl), *Eiten & Eiten 9058* (US); General Carneiro, Meruri [Meruré], Sep 1963 (fl), *Hartmann 369* (SP); 1 km NE of Garapú (13° 12'S, 52° 34'W), 300–400 m, 1 Oct 1964 (fl), *Irwin & Soderstom 6506* (MICH, MO, NY, RB); Mirassol D'Oeste, entre Cáceres e Pôrto Esperidiã, 23 Oct 1983 (fl), *Saddi 3477* (RB). **Minas Gerais:** São Gonçalo do Rio Preto, P. Farreras, Maripa-Aripao (7°29'N, 65°20'W), 80 m, Feb 1990 (fr), *Elcoro 686* (MO); Piar, Cerro Tomasote (7°48'N, 62°02'W), 540 m, May 1986 (fl), *Fernandez 2742* (MO); Represa Guri, 1–5 km S of dam (7°45'N, 63°0'W), 20–240 m, 1 Apr 1981 (fl), *Liesner & Gonzalez 11064* (ASU, MO, VEN); km 111 on Puerto Ordaz-Cerro Bolivar Railroad, 300–350 m, 26 Oct Chiguao (6°32'N, 63°8'W), May Jun 1987 (fl), *Stergios 11113* (MO); E of Miamo, Altiplanicie de Nuria, between Hato de Nuria and camp, 400 m, 23 Jan 1961 (fr), *Steyermark 88711* (NY, VEN); entre San Felix y Puerto Ordaz, opposite the Fabrica de Alfareria, 26 Jun 1964 (fr), *Steyermark 94291* (MICH). **Guarico:** Est. Biologica de los Llanos, ca. 12 km SE de Calabozo (8°56'N, 67°25'W), 75 m, 15 May 1987 (fr), *Ramirez 2182* (MO). **Mérida:** between Beguilla and Mucuchachí, 1065–2430 m, 4 May 1944 (fl, fr), *Steyermark 56312* (NY, VEN). **Portuguesa:** Llanos de Araure, 9 Apr 1925 (fl), *Pittier 11748* (NY). **Sucre:** Cumbre de Montaña de Mochima, 18 km SE de Cumana (10°20'N, 64°20'W), 350–400 m, 16 Sep 1973 (fr), *Steyermark et al. 108604* (MO, VEN). **Zulia:** Miranda, entre la via El Consejo-El Pensado y el Límite con el Edo. Falcón, 21 May 1980 (fl), *Bunting & Stoddart 9238* (NY).

Psidium salutare var. *salutare* (*P. salutare* in the traditional sense) is sometimes confused with *P. oligospermum* (=*P. sartorianum*). Their ranges are similar, both extending to central Mexico and the Caribbean and as far south as southeastern Brazil and Paraguay. They are compared in the key below.

1. Calyx open in the flower bud (closed corolla clearly visible); calyx lobes either evident or the margin of the calyx merely sinuate; subshrubs of open grasslands or scrub vegetation; petals 5–11 mm long; hairs when present ca. 0.5 mm long. _____ **P. salutare** var. **salutare**

1. Calyx closed in the flower bud (closed corolla hidden); calyx calyptrate or with terminal lobes (appearing puckered); shrubs to large trees, usually of forested habitats; petals 3–6 mm long; hairs when present up to ca. 0.2 mm long. _____ **P. oligospermum**

Psidium salutare var. *salutare* as understood here ranges from Paraguay to the Caribbean and Mexico and is quite variable. There are two local forms that might merit recognition as varieties: 1) Populations in Cuba have the calyx-lobes connate about 2–3 mm beyond the staminal ring; these have long gone under the name *P. guayabita*. 2) In Paraná to Rio Grande do Sul, Brazil and Paraguay there are populations with rather large elliptic to obovate, thinly pubescent leaves and include the types of *Myrcianthes reptans* and *Psidium valenzuelense*. Similar specimens occur in Central America, so it appears that *P. salutare* var. *salutare* is a morphologically flexible entity throughout its range.

Psidium salutare var. **decussatum** (DC.) Landrum, comb. nov. (**Figs. 2A, 6**). *Psidium decussatum* DC., Prodr. 3:235. 1828. TYPE: BRAZIL: "prov. Minarum," *Martius s.n.* (HOLOTYPE: M, = F-19710!, = ASU photo!).

Usually a subshrub less than 0.5 m high; leaves elliptic to narrowly elliptic, (1) 2–5.3 cm long, 0.7–1.7 cm wide, (1.5–)2.5–4.5 times as long as wide, glabrous (rarely sparsely pubescent); venation obscure, the marginal vein about 0.5 mm from margin; apex without an apiculum; peduncle 0.5–1.5 mm long, uniflorous (rarely triflorus); calyx-lobes shorter or about as long as hypanthial tube plus calyx tube, acute or rounded.

Representative specimens. **Distrito Federal:** 12 km W of Taguatinga, 1250 m, 26 Nov 1965 (fl), *Irwin et al. 10699* (NY); 2 km E of Lago Paranoá, DF-6, 1000 m, 26 Feb 1970 (fr), *Irwin et al. 26671* (NY); Chapada da Contagem, rd. NE edge Parque Nac. de Brasilia, Rua 4, 1160 m, 10 Sep 1995 (st), *Proença et al. 1458* (ASU, UB); ao lado da Reserva Biologica das Aguas Emendadas, 3 Sep 1995 (st), *Proença et al. 1496* (ASU, UB). **Goiás:** 10 km W of Cristalina (17°S, 48°W), 1200 m, 5 Mar 1966 (fr), *Irwin et al. 13548* (NY). **Minas Gerais:** Morro das Pedras, ca. 37 km NE of Patrocinio, 1000 m, 29 Jan 1970 (fr), *Irwin et al. 25600* (NY). **Paraná:** Colombo, Capivari, 4 Nov 1971 (fr), *Hatschbach 27711* (MBM); Rio Branco do sul, along road to Cerro Azul (ca. 25°S, 49°20'W), 7 Jan 1982 (fr), *Landrum 4110* (MICH, NY); Bocaiúva do Sul, Serra da Bocaina, 16 Jan 2001 (fr), *Ribas & Barbosa 3166* (ASU).

If this entity is recognized at the specific level the name *Psidium decussatum* DC. should be used. It seems to freely intergrade with var. *pohlianum* near Brasilia.

Psidium salutare var. **mucronatum** (Cambess.) Landrum, comb. nov. (**Figs. 2B, 6**). *Myrtus mucronata* Cambess., in Saint-Hilaire, Fl. Bras. merid. 2:295. 1833. TYPE: Saint-Hilaire s.n. "ad ripas fluminum Rio de la Plata et Uruguay in provincia Cisplatina," *Martius s.n.* (three specimens, P!, all marked as ISOTYPE, one= F neg. 36436!, [LECTOTYPE, here designated]).

Myrtus lurida Spreng., Syst. Veg. 2:480. 1825. TYPE: URUGUAY: "Monte Video," *Sello s.n.* (HOLOTYPE: B?, probably lost).

Myrtus pauciflora Cambess., in Saint-Hilaire, Fl. Bras. merid. 2:296. 1833. TYPE: "Encapamento do Ricao das galinhas in parte occidentali provinciae Cisplatinae," *Martius s.n.* (HOLOTYPE: P!, = F-36439!, = ASU photo!).

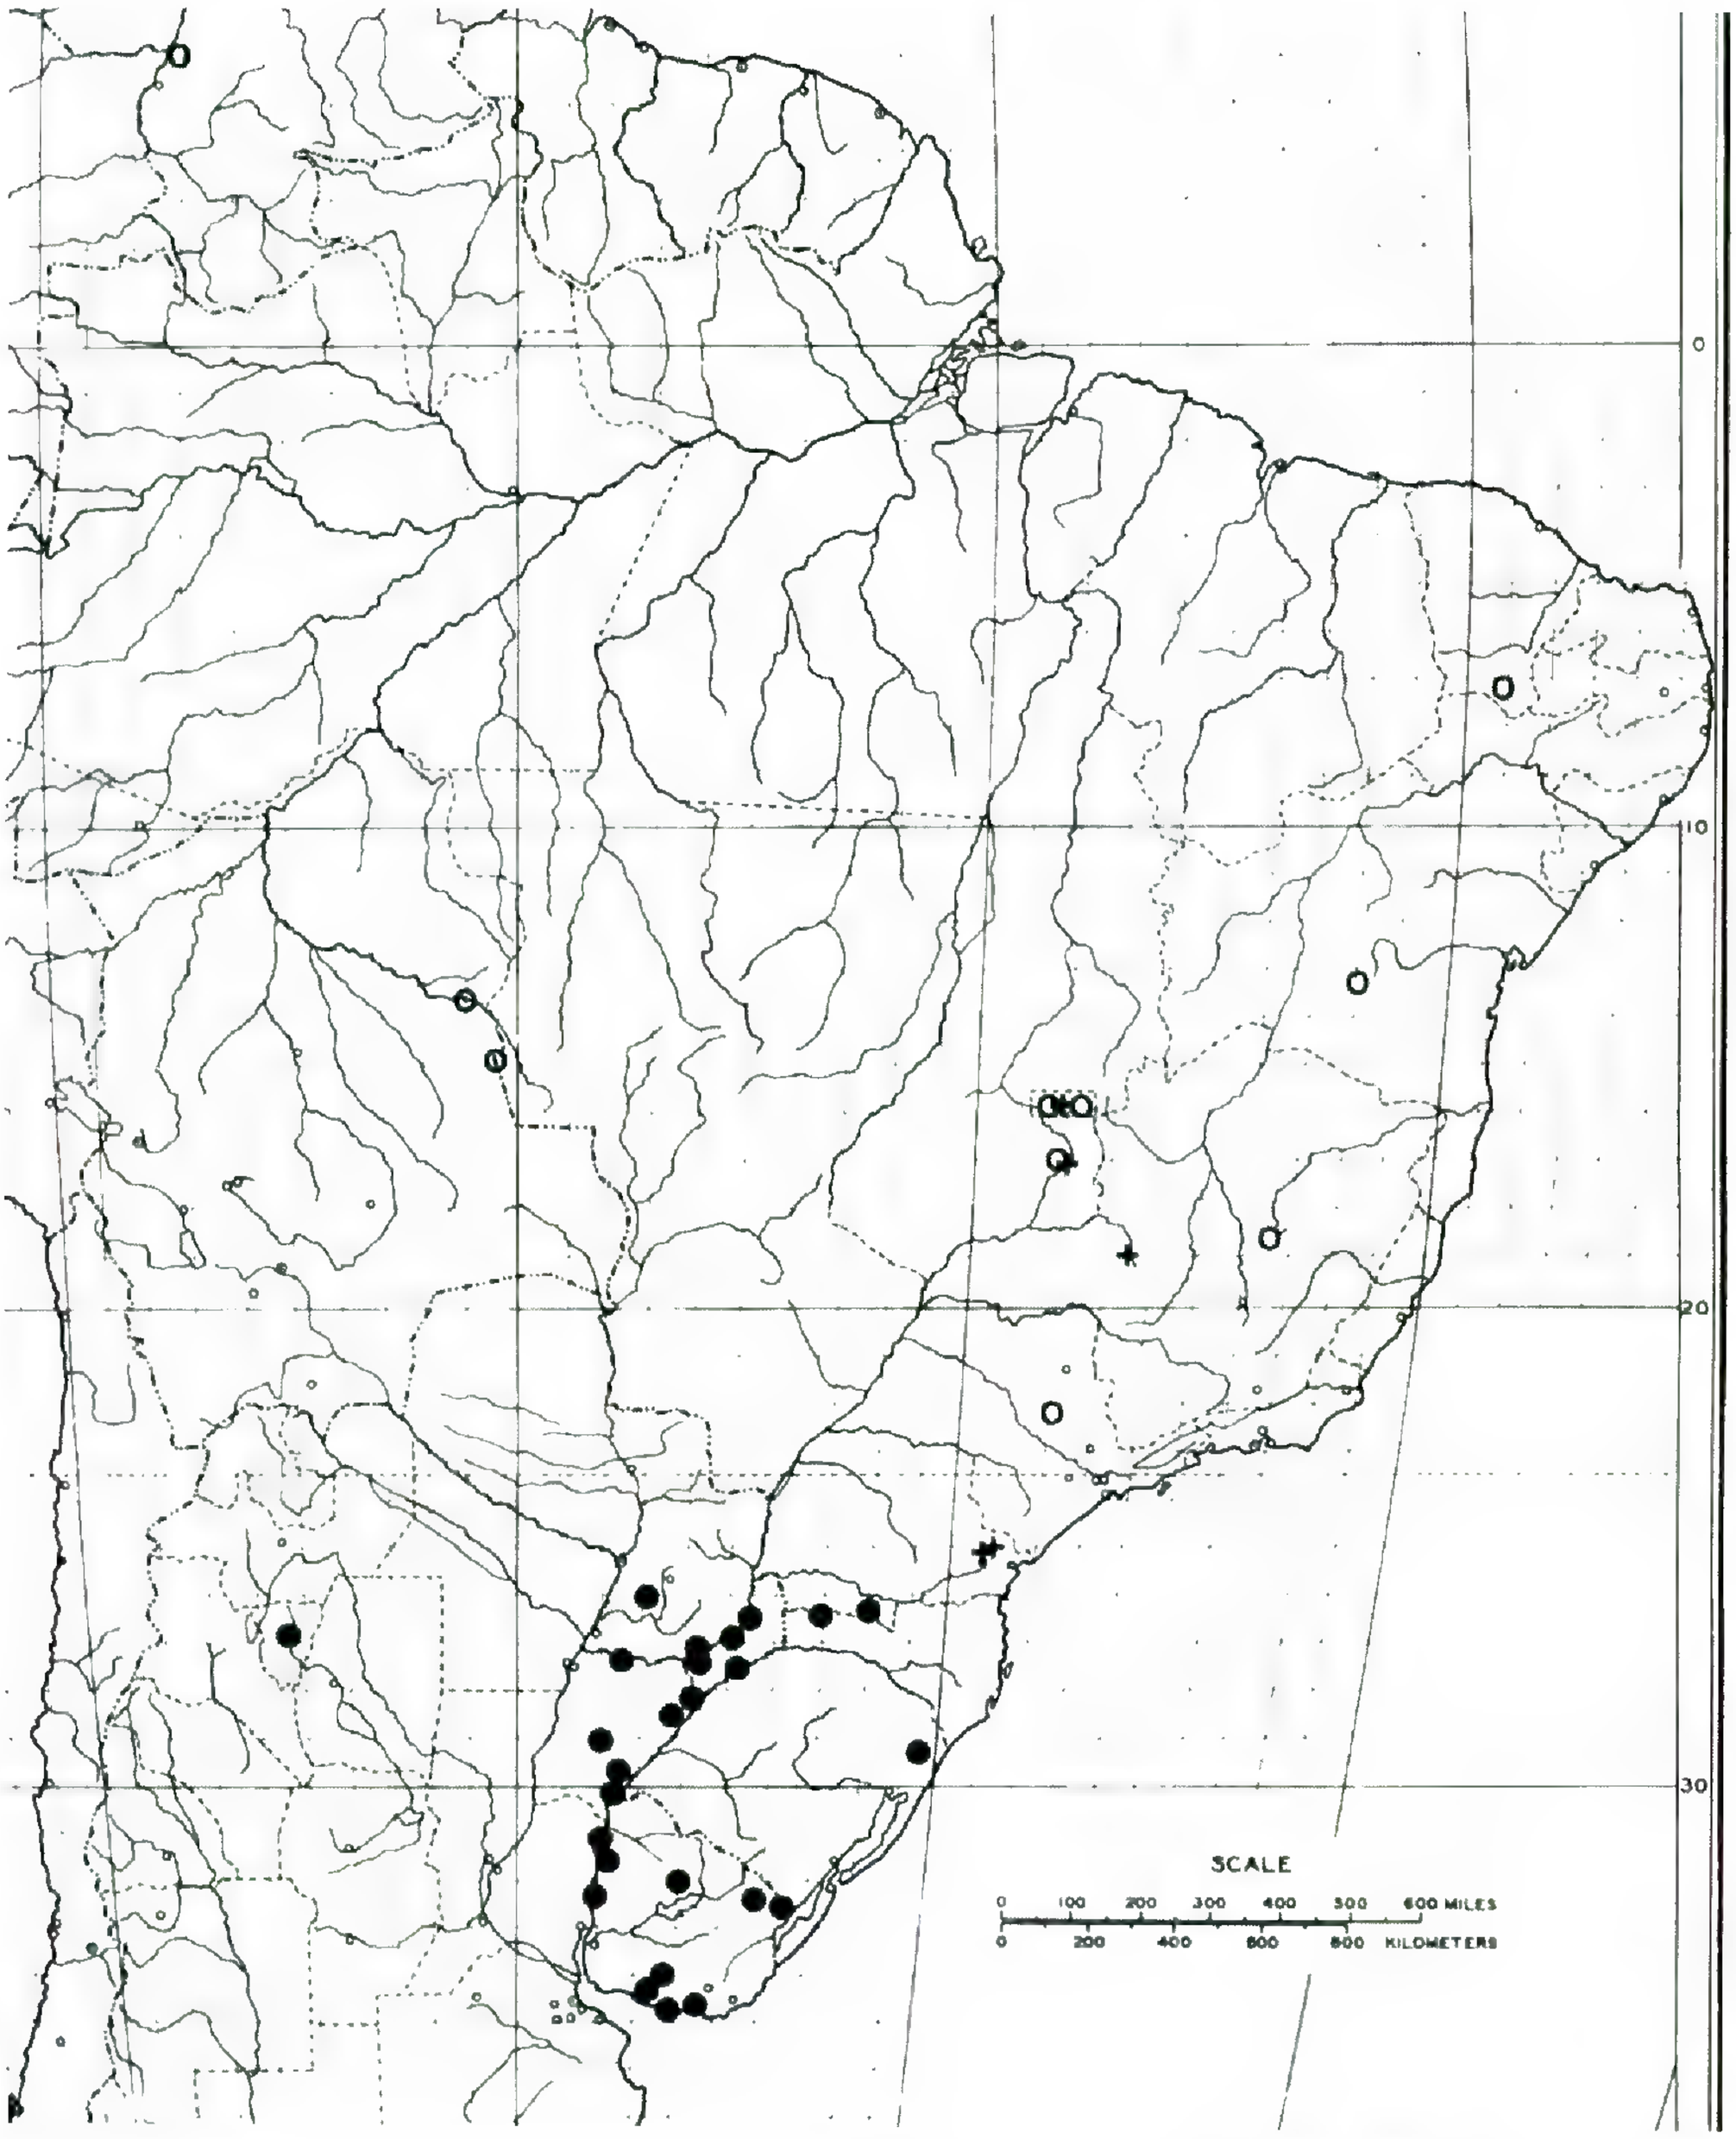

Fig. 6. Distribution of *Psidium salutare* var. *pohlianum* (open circles), *P. salutare* var. *decussatum* (crosses), and *P. salutare* var. *mucronatum* (dots).

Myrtus cuspidata O. Berg, in Mart., Fl. bras. 14(1):415. 1857. TYPE: URUGUAY: "in Montevideo," *Sellow s.n.* (SYNTYPES [types of the varieties] B, lost; ISOTYPE of *Myrtus cuspidata* var. *pentamera* at SGO! [LECTOTYPE, here designated], = ASU photo!).

Myrtus cuspidata var. *pentamera* O. Berg, in Mart., Fl. bras. 14(1):415. 1857. TYPE: URUGUAY: "in Montevideo," *Sellow s.n.* (HOLOTYPE: B, lost; ISOTYPE: SGO!, = ASU photo!). Name to be replaced with *Myrtus cuspidata* var. *cuspidata*.

Myrtus cuspidata var. *tetramera* O. Berg, in Mart., Fl. bras. 14(1):415. 1857. TYPE: URUGUAY: "in Montevideo," *Sellow* s.n. (HOLOTYPE: B, lost; ISOTYPE: SGO! [LECTOTYPE, here designated], = ASU photo!).

Myrtus mucronata var. *perforata* O. Berg, in Mart., Fl. bras. 14(1):416. 1857. Illegitimate name to be replaced by *M. mucronata* var. *mucronata*.

Myrtus mucronata var. *opaca* O. Berg, in Mart., Fl. bras. 14(1):416. 1857. TYPE: URUGUAY: "in Montevideo," *Sellow* s.n. (HOLOTYPE: B).

Myrtus ovalis O. Berg, in Mart., Fl. bras. 14(1):417 1857. TYPE: URUGUAY: "in Montevideo," *Sellow* s.n. (HOLOTYPE: B).

Myrtus suffruticosa O. Berg, in Mart., Fl. bras. 14(1):418 1857. TYPE: URUGUAY: "in Montevideo," *Sellow* s.n. (syntypes [types of the varieties] B, lost; ISOTYPE of *Myrtus suffruticosa* var. *latifolia* at P! [lectotype, here designated], = ASU photo!).

Myrtus suffruticosa var. *latifolia* O. Berg, in Mart., Fl. bras. 14(1):418. 1857. TYPE: URUGUAY: "in Montevideo," *Sellow* s.n. (HOLOTYPE: B, lost; ISOTYPE: P! [LECTOTYPE, here designated], = ASU photo!).

Myrtus suffruticosa var. *angustifolia* O. Berg, in Mart., Fl. bras. 14(1):419. 1857. TYPE: URUGUAY: "in Montevideo," *Sellow* s.n. (HOLOTYPE: B, lost).

Myrtus acutata O. Berg, in Mart., Fl. bras. 14(1):415. 1857. TYPE: URUGUAY: "in Montevideo," *Sellow* s.n. (HOLOTYPE: B, lost; ISOTYPES, P [two specimens] , one = F-36424! [LECTOTYPE, here designated]).

Myrtus sellowiana O. Berg, in Mart., Fl. bras. 14(1):413. 1857. TYPE: BRAZIL: "ad Tapanhoacanga prov. Minarum," *Sellow* s.n. (HOLOTYPE: B, lost; ISOTYPE: P!, = F-36445! [LECTOTYPE, here designated], = ASU photo!).

Psidium thea Griseb., Pl. lorentz. 91. 1874, and in Goett. Abh. 19:139. 1874. TYPE: ARGENTINA: "Cordoba, in monte Cerro negro pro. San Bartolo., Tucuman," *Hieronymus?* (HOLOTYPE: probably GOET; possible ISOTYPE: P = F-36422!).

Myrtus mucronata var. *thea* (Griseb.) Griseb. Abh. Konigl. Ges. Wiss. Gottingen 24:127. 1879.

Psidium luridum (Spreng.) Burret, Notizbl. Bot. Gart. Berlin-Dahlem 15:484. 1941.

Psidium pubifolium Burret, Notizbl. Bot. Gart. Berlin-Dahlem 15:484. 1941. New name for *Myrtus ovalis* O. Berg.

Psidium luridum var. cinereum Mattos, Loefgrenia 64:2. 1975. TYPE: BRAZIL: Santa Catarina, "Campo Erê, 17 km W of Campo Erê, ca. 26° 22'S, 53° 08' W, 900–1000 m," *Smith & Klein 13807* (HOLOTYPE: HBR, ISOTYPE: R!, = ASU photo!).

Psidium pubifolium f. nanum Rotman, Darwiniana 20:433. 1976. TYPE: BRAZIL. Santa Catarina, "Campo Erê, 37 km W of Campo Erê, ca. 26° 22'S, 53° 08'W, 900–1000m," *Smith & Klein 13807* (HOLOTYPE: MVM, ISOTYPE: R!, = ASU photo!).

Usually a subshrub less than 0.5 m high; leaves mostly narrowly elliptic to lanceolate, (1.5–)2–6 cm long, 0.7–2.3 cm wide, (1.4–)1.5–5 times as long as wide, glabrous to subglabrous, often lustrous; venation pronounced, raised on both surfaces, the marginal vein usually within 1 mm of the margin; apex apiculate; peduncle often over 2 cm long, uniflorous; calyx-lobes usually longer than hypanthial tube plus calyx tube, usually acute.

Representative specimens. **ARGENTINA. Corrientes:** 2 5 km de la ciudad de Monte Caseros, 28 Dec 1968 (fr), *Carnevali 1317* (CTES); Paso de Los Libres, Bonpland, costa río Uruguay, 19 Jan? 1945 (fr), *Ibarrola 2135* (NY); Santo Tomé, 33 km N de Santo Tomé, 27 Jan 1976 (fl), *Krapovickas & Cristobal 28934* (CTES, NY); Ituzaingó, Rincón Ombú Chico, 3–5 Jul 1974 (fl), *Krapovickas et al. 25477* (CTES, MICH); Mercedes a Itá Corá, Ayo. BRAZIL. Paraná: Palmas, Rio Chopim, 7 km abaixo da nascente, 20 Nov 1990 (fl), *Hatschbach 54810* (ASU, MBM). **Rio Grande do Sul:** São Francisco de Paula, (fr), *Rambo 30793* (MICH); Bom Jesus, Fazenda B. Velho, 4 Jan 1947 (fr), *Rambo 35177* (MO, NY).

PARAGUAY. Itapua: Arroyo Guazu Acatí, 15 Sep 1983 (fl), *Basualdo s.n.* (FCQ); Capitán Miranda, 4.2 km N of entrance to Hotel Tirol (ca. 27°12'S, 55°45'W), ca. 210 m, 13 Aug 1995 (st), *Landrum 8665* (ASU). **Paraguarí:** National Park Ybycuí, NE corner of the park on Arroyo Corrientes (26°03'S, 56°50'W), 21 Dec 1988 (fr), *Zardini et al. 9015* (PY).

URUGUAY. Artigas: ruta 30, 7 km S de Artigas, 10 Dec 1995 (fr), *Solis Neffa et al. 242* (CTES); Cerro Largo: S of Melo, 48 km, 9 Jan 1944 (fr), *Bartlett 21279* (MICH). **Maldonado:** Sierra de Animas, ca. 65 km E of Montevideo (ca. 34°45'S, 55°30'W), 22 Nov 1981 (fl), *Landrum 3856* (NY). **Montevideo:** Punta Espinillo, (fl), *Legrand 2710* (MICH); Chapicuy, orillas del río Uruguay, Sta Sofia, 15 Nov 1942 (fl), *Rosengurtt et al. B-4183* (MO, NY); Rocha: Santa Teresa, (fl), *Legrand MVM-1064* (MICH). **San José:** Rincón Gallinas, 5 m, Dec 1931 (fl), *Herter 88052* (NY, RB). **Tacuarembó:** Gruta de los Cuervos, 17 Jan 1944 (fr), *Legrand 3338* (NY).

There are many intermediates between typical var. *mucronatum* (which is glabrous) and typical var. *sericeum* (which is densely covered with silvery hairs). The fact that these varieties also have similar distributions, leads me to suspect that there is a simple genetic difference between them. Intermediates have mainly been identified as var. *sericeum*.

Psidium salutare var. *mucronatum* frequently grows with *P. missionum* and can easily be confused with that species. The two species are contrasted in the key below.

1. Leaves 2–4.5 cm long, 0.7–2.3 cm wide, 1.5–5 times as long as wide; marginal vein distinct, closely following the margin; placenta protruding, peltate; style 5–6 mm long, glabrous. _____ **P. salutare** var. **mucronatum**
1. Leaves 2.5–8.8 cm long, 1.1–4 cm wide, 1.8–3.5 times as long as wide; marginal vein evident only in distal portion of leaf, arching broadly between laterals; placenta protruding only slightly, not peltate; style 7–9 mm long, usually with a few scattered hairs. _____ **P. missionum**

If the entity here called *Psidium salutare* var. *mucronatum* is recognized at the specific level, the name *P. luridum* (Spreng.) Burret should be used. There may be no type specimen of *Myrtus lurida* in existence, having been at B and now destroyed. Burret (1941), who studied the type shortly before it was destroyed, listed *Myrtus cuspidata* as a synonym. That coupled with Sprengel's protologue leave little doubt as to its identity. The type of *Myrtus ovalis* at B was also destroyed, but the protologue is sufficient to consider it a synonym of this variety.

Psidium salutare var. **pohlianum** (O. Berg) Landrum, comb. nov. (**Figs. 2C, 6**).

Psidium pohlianum O. Berg, in Mart. Fl. bras. 14(1):390. 1857. TYPE: BRAZIL: "ad S.

Luzia in prov. Goyazensi," *Pohl 913*, *Sellow s.n.* (SYNTYPES B, lost; SYNTYPE [*Pohl 913*], W, = F-31431!; ISOSYNTYPE [*Sellow s.n.*], P!, [LECTOTYPE, here designated], = ASU photo!).

Psidium pohlianum var. *brevipes* O. Berg, in Mart., Fl. bras. 14(1):601. 1859. TYPE: BRAZIL: "prope S. Carlos prov. S. Pauli," *Riedel s.n.* (apparent HOLOTYPE 2 sheets at LE, =ASU photos!).

Shrub or tree to 10 m high; leaves mostly elliptic, to obovate, or oblanceolate, 4–9 cm long, 2–5.5 cm wide, 1.4–2.7(–3.5) times as long as wide, glabrous; venation pronounced, raised on both surfaces, the marginal vein usually about 1 mm from the margin; apex usually without an apiculum; peduncle 0.4–2 cm long, often triflorous; calyx-lobes shorter or about as long as hypanthial tube plus calyx tube, rounded to obtuse.

Representative specimens. **BOLIVIA. Santa Cruz:** P. N. Noel Kempff Mercado, Pista Las Gamas, (14°48'11"S, 60°23'35"W), 815 m, 9 Nov 1993 (fr), *Guillén & Centurión 1023* (ASU); P. N. Noel Kempff Mercado, 6 km SW del campamento Las Gamas (14°49'36"S, 60°23'10"W), 850 m, 30 Oct 1995 (fr), *Rodriguez & Surubí 592* (ASU); P. N. Noel Kempff Mercado, Huanchaca I, (13°53'55"S, 60°48'46"W), 850 m, 3 Nov 1995 (fr), *Rodriguez & Surubí 630* (ASU).

BRAZIL. Bahia: near Junco, ca. 15 km WNW of town of Rio de Contas (41°55'W, 13°32'S), 22 Jan 1974 (fr), *Harley 15596* (ASU, MICH). **Ceará:** Crato, Barreiro Grande- Agreste, 2 Apr 1995 (fr), *Silveira 22103* (RB). **Distrito Federal:** 10 km E of Planaltina, 1150 m, 10 Oct 1965 (yfr), *Irwin et al. 9101* (NY); Chapada da Contagem, rd. NE edge Parque Nac. de Brasilia, Rua 1, 1160 m, 1160 m, 10 Sep 1995 (fl), *Proença et al. 1455* (ASU, UB). **Goiás:** Serra dos Cristais, ca. 12 km E of Cristalina (17°S, 48°W), 1200 m, 9 Mar 1966 (fr), *Irwin et al. 13226* (CAS, MICH, NY); Serra dos Cristais, ca. 3 km W of Cristalina (17°S, 48°W), 1250 m, 3 Mar 1966 (fr), *Irwin et al 13367* (CAS, NY). **Minas Gerais:** Palacio, Serra do Cipó, 150 km N of Belo Horizonte, 1450 m, 20 Feb 1968 (fl), *Irwin et al. 20561* (F); 4 km N of Patrocinio, 1000 m, 31 Jan 1970 (fr), *Irwin et al. 25733* (NY). **São Paulo:** Itirapina, Estrada de Graúna, 2 Feb 1993 (fr), *Fabio de Barros 2515* (ASU).

VENEZUELA. Amazonas: Atures, ca. 30 km al N de Puerto Ayacucho y a unos 5 km al NE de Galipero (5°48'N, 67°20'W), 80 m, 9 May 1980 (yfr), *Huber 5210* (MICH, MO, NY, VEN); Atures, Rincones de Chacorro, 30 km N de Puerto Ayacucho, 5 km NE de Galipero (5°48'N, 67°20'W), ca. 80 m, 27 Feb 1982 (fl), *Huber 6289* (MICH, MO, NY, VEN); Atures, road NE from Puerto Ayacucho, 27.5 km towards El Burro, 28 Apr 1984 (fr), *Plowman & Guanchez 13756* (CAS, F, MO, NY, RB). **Bolivar:** Río Parguaza, 13 Apr 1946 (fl), *Velez 2374* (US, VEN).

If the entity here called *Psidium salutare* var. *pohlianum* is recognized at the specific level , the name *Psidium pohlianum* O. Berg should be used. As mentioned above, this variety intergrades with var. *decussatum* in the vicinity of Brasilia.

Two specimens at LE fit the protologue of *Psidium pohlianum* var. *brevipes*, but are annotated by Berg as to species only. I assume these specimens to represent the holotype of var. *brevipes*. One specimen is mixed with a fragment of *P. guineense*.

Psidium salutare var. **sericeum** (Cambess.) Landrum, comb. nov. (**Figs. 2D, 5**).

Myrtus sericea Cambess., in Saint-Hilaire, Fl. Bras. merid. 2:295. 1833. TYPE: BRAZIL: "Capilha de Mercedes... provinciae Cisplatinae, necnon... Rincao de Saneloés ad ripam amnis Ibicuy in provincia Missionum," *Saint-Hilaire s.n.* (HOLOTYPE: P!, = F-36446!; ISOTYPE: P!, = ASU photo!).

This entity has long gone by the name *Psidium incanum* (O. Berg) Burret, which is the correct name if one recognizes it at the specific level. It most closely resembles var. *mucronatum* and intergrades with it.

ACKNOWLEGMENTS

I am grateful to the curators of the following herbaria who kindly allowed me to study their specimens on loan, as images, or as a visitor (ALCB, ASE, BR, CAS, CEPEC, CTES, EAP, F, FCQ, G, GH, HB, HBR, HRB, HUEFS, K, LE, LIL, MBM, MEXU, MICH, MO, NY, MY, OXF, P, PY, QCA, QCNE, R, RB, SGO, SP, TEFH, UB, UC, US, USM, USP, VEN, WIS). Alexander N. Sennikov has been especially helpful in providing images of types at LE. My Latin American colleagues C. Nelson, R. Bye, I. Basualdo, E. Zardini, C. Proença, M. L. Kawasaki, A. Krapovickas, G. Hatschbach, and M. Sobral have helped in many ways. Herbarium visits and fieldwork was supported by a Fulbright American Republics grant and by a National Geographic Society grant. N. Snow and an anonymous reviewer offered many helpful suggestions.

BOOK NOTICES

Systematics/Monographs/Floras/Guides

GEYATA AJILVSGI. 2002. **Wildflowers of Texas. Revised Edition.** (ISBN 0-940672-73-1, pbk, laminated). Shearer Publishing, 406 Post Oak Road, Fredericksburg, TX 78624, U.S.A. (Orders: 800-458-3808, www.shearerpub.com). $19.95, 524 pp., numerous color photographs, 4 1/2 × 7 1/2".

From the inside cover flap.—"IN this revised edition of her popular *Wildflowers of Texas*, native-plant expert Geyata Ajilvsgi gives lay readers the most comprehensive field guide currently available on the state's abundant wildflowers. With the addition of 105 species, the book now contains, information on 482 of the most common wildflower species found in the state's major vegetation zones—from the mountains in the west to the swamplands in the east, from desert to piney woods to coastal plain, from the Panhandle to the semitropical Rio Grande Valley. Each entry reflects the most current scientific knowledge about the plant, such as recent changes in taxonomic classification."

The layout is nice with color photographs on the left side of the page and text on the right. Every plant listed includes a common name, family, bloom period, description, habitat, and a general note about the plant. It is fun to just read the various comments about individual species. The field guide includes a glossary, an illustrated glossary (floral structures, vegetative structures), selected bibliography that includes many up-to-date references, and an index of Latin names and a wealth of common names.—*Barney Lipscomb, Botanical Research Institute of Texas, 509 Pecan St, Fort Worth, TX 76102-4060, U.S.A., barney@brit.org.*

ROBERT H. MOHLENBROCK. 2002. **The Illustrated Flora of Illinois. Grasses: *Bromus* to *Paspalum*. Second Edition.** (ISBN 0-8093-2359-1, hbk.) Southern Illinois University Press. P.O. Box 3697, Carbondale, IL 62902-3697, U.S.A. (Orders: 618-459-6633, 618-453-1221 fax, www.siu.edu/~siupress). $60.00, 416 pp, 284 line drawings, 6" × 9".

ROBERT H. MOHLENBROCK. 2002. **Vascular Flora of Illinois.** (ISBN 0-8093-2421-0, pbk.) Southern Illinois University Press. P.O. Box 3697, Carbondale, IL 62902-3697, U.S.A. (Orders: 618-459-6633, 618-453-1221 fax, www.siu.edu/~siupress). $50.00, 736 pp, 1 map (county map of Illinois), 6" × 9".

The Illustrated Flora of Illinois. Grasses: Bromus to Paspalum. Second Edition The second edition features 22 newly discovered taxa since the first edition in 1972. "For each new species, a full-page illustration is provided. This second edition updates the status of Illinois grasses. The book features 263 figures from the first edition plus 21 new figures for this edition by Paul W. Nelson." The drawings are excellent. Keys and distribution maps are included.

Vascular Flora of Illinois is the sequel to the first edition published in 1975 and to the second and enlarged edition in 1986. The latest edition covers over 3200 taxa, an increase of almost 300 since 1986. Besides keys to genera and species, common names, flowering times, habitats, and geographical distribution, the taxa below the rank of species are recognized and may be identified by keys.—*Barney Lipscomb, Botanical Research Institute of Texas, 509 Pecan St, Fort Worth, TX 76102-4060, U.S.A., barney@brit.org.*

REVISION AND TYPIFICATION OF SOME SPECIES OF *IXORA* (RUBIACEAE) FROM CENTRAL AND SOUTHERN BRAZIL

Piero G. Delprete[1]

Institute of Systematic Botany
The New York Botanical Garden
Bronx, NY 10458-5126, U.S.A.
pdelprete@nybg.org

ABSTRACT

In connection with the treatment of *Ixora* for the *Flora Fanerogâmica do Estado de São Paulo*, *Flora Ilustrada Catarinense* and *Flora de Goiás e Tocantins*, it was necessary to undertake a taxonomic study of the taxa occurring in Central and Southern Brazil. Five native species occur in the state of São Paulo, and 12 taxa originally described by Müller Argoviensis are here treated as synonymous with the recognized species. Only one native species occurs in the state of Santa Catarina. Full typification, synonymies, brief descriptions, specimens cited, and a key to the *Ixora* of São Paulo are here presented.

KEY WORDS: *Ixora*, Ixoroideae, Rubiaceae, typification, Brazil.

RESUMEN

En conexión con el tratado de *Ixora* por la *Flora Fanerogâmica do Estado de São Paulo*, la *Flora Ilustrada Catarinense* y la *Flora de Goiás e Tocantins* fue necesario realizar un estudio taxonómico de los taxa presentes en Brasil central y meridional. Cinco especies nativas ocurren en el estado de São Paulo y doce taxa originariamente descritos por Müller Argoviensis son tratados aquí como sinónimos de especies reconocidas. Solamente una especie nativa ocurre en el estado de Santa Catarina. Se presentan aquí tipificaciones y sinonimias completas, descripciones, especímenes citados y una clave para las especies de *Ixora* de São Paulo.

Ixora is a pantropical genus of about 350 species, with most of them present in tropical Asia and the islands of the South Pacific, about 37 species in continental Africa, about 35 species in Madagascar, and about 45 species in the Neotropics. Although the African species have been recently studied by De Block (1998), revisions for the Neotropical or the Asiatic species have never been attempted.

During the preparation of the treatment of *Ixora* for the *Flora Fanerogâmica do Estado de São Paulo* (Delprete, in press) and *Flora Ilustrada Catarinense* (Delprete et al., submitted), and *Flora de Goiás e Tocantins*, it was necessary to examine material from many Brazilian and international herbaria, and to study the type specimens of the species described by Bentham (1850) and Müller Argoviensis (1875, 1881).

Johannes Müller (1828–1896) was renamed by C.F.P. von Martius (coordi-

[1]Current address: National Herbarium of the Netherlands, Utrecht University branch, Plant Systematics, Heidelberglaan 2, 3584 CS Utrecht, The Netherlands, E-Mail: pdelprete@hotmail.com

nator of *Flora Brasiliensis*) as Müller Argoviensis (because he was native of a small town in the canton of Aargau, Switzerland), to distinguish him from other contemporary botanists with the same last name. The personal herbarium of Müller Argoviensis was subsequently included in the Candolle Herbarium (G-DC). Because of their historical value, the specimens of this herbarium are not sent out on loan. In order to examine the type specimens of the *Ixora* species described by Müller Argoviensis, a set of about 80 black and white negatives were made by the staff of the G-DC Herbarium and sent to NY. The negatives were used to make large photographs, which were mounted on NY herbarium sheets. The present work would have not been possible without the close examinations of these photographs.

The most complete treatment of Brazilian species of *Ixora* still remains that of Müller Argoviensis (1881), where he expanded the original descriptions of his new species published a few years before (Müller Argoviensis 1875), and cited additional specimens of contemporary collectors. In his treatments, he distinguished the species of *Ixora* based on leaf shape, presence of colleters inside the calyx, and presence and shape of leaf-like bracts subtending the secondary branches of the inflorescences. All these characters are here considered of little taxonomic significance, and most of Müller Argoviensis' new taxa here studied are reduced to synonymy. In addition, the fruits of the species examined are quite uniform, in being spherical to subspherical and 5–7 mm in diameter, usually reddish to deep red, and consequently without any useful taxonomic characters. Most of the characters considered of taxonomic significance in the definition of the species presented below were found in the stipule shape, length of the stipular arista, leaf venation, inflorescence size and architecture, number of inflorescence secondary branches, flower bud shape (ovoid or oblong-ellipsoid at apex), corolla tube length, corolla lobes length and shape, and corolla tube/lobe ratio. A key to the species of the State of São Paulo is presented below.

Full typification and citation of specimens examined is here presented because this information can not be included in the concise format of the *Flora Fanerogâmica do Estado de São Paulo*. It is my hope that this work will provide an initial contribution towards the clarification of *Ixora* from central and southern Brazil; however, considerable work remains to be done before a revision of the Brazilian species of this difficult genus can be completed.

Ixora brevifolia Benth., Linnaea 23:448. 1850. TYPE: BRAZIL. MINAS GERAIS: without locality, 1845–1846 (fl), *Widgren 1119* (LECTOTYPE: UPS! V-134607, here selected; ISOLECTOTYPE: UPS n.v. V-102640; not at GOET, K, S).

Ixora thyrsoidea Muell. Arg., **syn. nov.**, Flora 58:455, 459. 1875. TYPE: BRAZIL. BAHIA: without locality, 1857, *Blanchet s.n.* (HOLOTYPE: G-DC n.v., photos at NY!).

Ixora warmingii Muell. Arg., **syn. nov.**, Flora 58:455, 459. 1875. TYPE: BRAZIL. MINAS GERAIS: Lagoa Santa, s.d. [1863–1865], *Warming s.n.* (LECTOTYPE: G-DC n.v., here selected, photos at C!, NY!).

Ixora glaziovii Muell. Arg., **syn. nov.**, in Mart , Fl. Bras. 6(5):460. 1881. TYPE: BRAZIL. RIO DE JANEIRO: Without locality, s.d. [1861–1895], *Glaziou 10932* (HOLOTYPE: G-DC n.v., photos at NY!; ISOTYPE: B†, photo at NY!).

Ixora membranacea Muell. Arg., **syn. nov.**, in Mart., Fl. Bras. 6(5):458. 1881. TYPE: BRAZIL. RIO DE JANEIRO: without locality, s.d. [1861–1895], *Glaziou 10947* (HOLOTYPE: G-DC n.v., photos at NY!; ISOTYPE: B†, photo at NY!).

Tree up to 20 m tall, to 35 cm at dbh; bark smooth; branchlets glabrous. **Stipules** 4–8 × 3–4 mm, base deltoid, arista 4–6 mm long, glabrous outside, densely sericeous-pubescent and intermixed with colleters inside. **Leaf** blades narrowly elliptic, oblong elliptic to obovate, (4–)8–20 × 1.5–6(–8) cm, apex acute or acuminate, base acute to round, subcoriaceous to coriaceous, glabrous; secondary veins 15–40 each side, tertiary venation subparallel-reticulate; petioles 4–10 mm long, glabrous. **Inflorescences** sessile or pedunculate, paniculate, multiflorous, 5–12 × 3–8 cm, with 2 or 3 lateral branches, these sparsely branches or corymbose; peduncles 2.5–4 cm long, or absent; **bracts** subtending the secondary branches narrowly triangular, 1–4 mm long; **bracteoles** triangular, 0.4–0.7 mm long. **Flower buds** oblong-ellipsoid at apex. **Pedicels** absent or to 2 mm long. **Flowers** sessile or short-pedicellate, fragrant. **Calyx** 0.7–1 mm long; lobes triangular or ovate, glabrous. **Corolla** 6–9 mm long, cream-white; tube 2.6–3.7 × 1–1.5 mm, glabrous outside, pubescent inside; lobes oblong, 3–5 × 0.8–2 mm, apex round, glabrous. **Stamens** 3.5–4.5 mm long; anthers narrowly oblong, ca. 2.5 mm long, apex acute. **Style** ca. 4–6 mm long; style branches narrowly oblong, ca. 2 mm long. **Fruit** globose, 5–6.5 mm diam., glabrous, red.

A species occurring in the states of Minas Gerais, Goiás, Distrito Federal, Mato Grosso, Bahia, Rio de Janeiro, Espirito Santo and São Paulo, usually found in the moist forests of the coastal states, and in the gallery forests of the cerrado biome of central Brazil. Many specimens have been traditionally annotated as *Ixora warmingii*, which is a later synonym of this species.

Because *Ixora brevifolia* Benth. was originally described by Bentham (1850), the type material was expected to be housed at K. After two distinct searches by the K herbarium staff, no type material (*Pohl s.n.* and *Widgren 1119*) pertaining to this species was found at this institution. Therefore, a search of duplicate specimens of *Widgren 1119* was initiated in the main herbaria where Widgren's collections were distributed (C, GOET, S, UPS; Vegter, 1988). Two duplicates of *Widgren 1119* were found at UPS, one of which is here selected as the lectotype of *Ixora brevifolia*.

Ixora gardneriana Benth., Linnaea 23:448. 1850. TYPE: BRAZIL. RIO DE JANEIRO: woods of Tijuca, Dec 1840, *Gardner 5496* (HOLOTYPE: K!, photo at NY!; ISOTYPE: K!).

Ixora schottiana Muell. Arg., **syn. nov.**, Flora 58:455, 459. 1875. TYPE: BRAZIL. RIO DE JANEIRO: Serra Tingua, s.d. [1817–1820], *Schott 889* (LECTOTYPE: G-DC n.v., here selected, photos at NY!; ISOTYPE: K!, photo at NY!).

Ixora riedeliana Muell. Arg., **syn. nov.**, Flora 58:455, 459. 1875. TYPE: BRAZIL [Southern Brazil]: without locality, s.d. [1821–1836], *Riedel s.n.* ["478"] (HOLOTYPE: G-DC n.v., photos at NY!; dubious ISOTYPE: NY!).

Ixora obscura Muell. Arg., **syn. nov.**, Flora 58:455, 459. 1875. TYPE: BRAZIL [Southern Brazil]: without locality, s.d. [1815–1817], *Sello s.n.* (HOLOTYPE: G-DC n.v., photos at NY!; ISOTYPE: B† [*Sello 6018*], photo at NY!).

Ixora truncata Muell. Arg., **syn. nov.**, in Mart., Fl. Bras. 6(5):459. 1881. TYPE: BRAZIL. RIO DE JANEIRO: Rio de Janeiro, s.d. [1861–1895], *Glaziou 10933* (LECTOTYPE: G-DC n.v., here selected, photos at NY!; ISOLECTOTYPE: B†, photo at NY!).

Tree; bark smooth; branchlets glabrous. **Stipules** 2.5–3.5 × 1.5–2 mm, base deltoid, arista 1.5–2 mm long, glabrous outside, densely sericeous-pubescent and intermixed with colleters inside. **Leaf** blades elliptic or ovate, 5–13 × 2.5–5.5 cm,

apex acute, base acute, subcoriaceous, glabrous; secondary veins 6–14 each side, tertiary venation reticulate; petioles 5–12 mm long, glabrous. **Inflorescences** pedunculate, paniculate, pauci- or multi-florous, 5–11 × 3.5–6 cm; peduncles 0.5–2.5 cm long; **bracts** subtending the secondary branches often foliose, narrowly triangular to obovate, 5–10 mm long; **bracteoles** 1 or 2 per flower, triangular, 2–3 mm long, or absent. **Flower buds** ovoid at apex. **Pedicels** 2–7 mm long. **Flowers** pedicellate (rarely sessile), fragrant. **Calyx** 0.8–1 mm long; lobes deltoid, glabrous. **Corolla** 8–9 mm long, cream-white; tube 4.5–5.5 × 1–1.2 mm, glabrous outside, pubescent inside; lobes ovate, 3.5–4 × 2–2.5 mm, apex round, glabrous. **Stamens** 3.5–4 mm long; anthers narrowly oblong, 3.2–3.7 mm long, apex apiculate. **Style** 10.5–11 mm long; style branches narrowly oblong, 1.7–2 mm long. **Fruit** unknown.

Illustration.—Mart., Fl. Bras. 6(5), Tab. 9. 1881 (as *Ixora schottiana*).

Additional specimens examined. **BRAZIL. São Paulo:** São Paulo, Fda. Itatuba, 23 Dec 1931 (fl), *Amaral s.n. (SP 28628)* (NY, SP); São Paulo, Jardim Botânico, tree n. 179, 9 Dec 1931 (fl), *Hoehne s.n. (SP 28588)* (NY[2], SP); Mun. Campinas, Bosque de São José, 13 Sep 1994 (fl), *Santin & Bertani s.n. (UEC 33566)* (NY, UEC).

A very rare species, and certainly in danger of extinction, that occurs in the Atlantic forests of the states of Rio de Janeiro (Serra do Tinguá e Serra da Estrella) and São Paulo (Fda. Itatuba and Bosque de São José).

The holotype specimen has the stamp "Herbarium Benthamianum" and a label with the handwriting "5496, *Ixora Gardneriana* Benth, Linnaea 13:448" and the print "Brasilia, Gardner, 1841." Whereas the isotype specimen has the stamp "Herbarium Hookerianum" and the handwritten label "5496, *Faramea* sp., a large shrub - woods of Tijuca, Dec./[18]40." Because the label of the isotype was handwritten by Gardner, the locality and date reported on this specimen are considered more accurate.

Ixora heterodoxa Muell. Arg., Flora 58:454, 459. 1875. TYPE: BRAZIL. RIO DE JANEIRO: near Rio de Janeiro, s.d. [1861–1895], *Glaziou 6154* (HOLOTYPE: G-DC n.v., photos at NY!; ISOTYPE: B†, photo at NY).

Ixora burchelliana Muell. Arg., **syn. nov.**, Flora 58:454, 458. 1875. TYPE: BRAZIL. SÃO PAULO: "Prov. São Paulo," s.d. [1825–1830], *Burchell 3208* (HOLOTYPE: fragments G-DC n.v., photos at NY!; ISOTYPE: BR!).

Ixora dimorphophylla Muell. Arg., **syn. nov.**, Flora 58:454, 458. 1875. TYPE: BRAZIL. Rio de Janeiro: Without locality, *Glaziou 705* (HOLOTYPE: C!, photo at NY!; ISOTYPES: BR!, K!; photo-K at NY!).

Ixora heterophylla Muell. Arg., **syn. nov.**, in Mart., Fl. Bras. 6(5):68. 1881. TYPE: BRAZIL. RIO DE JANEIRO: Serra Estrella, in fruticetis umbrosis, s.d. [1821–1836], *Riedel 342* (HOLOTYPE: G-DC n.v., photos at NY!; ISOTYPE: BR!).

Shrub 2–3(–5) m tall, rarely trees 5–8 m tall, 10–15 cm at dbh; bark smooth; branchlets glabrous. **Stipules** 5–6 × 2.5–3.5 mm, base deltoid, arista 2–3.5 mm long, glabrous outside, densely sericeous-pubescent and intermixed with colleters inside. **Leaf** blades ovate, elliptic to obovate, 5–18 × 2.5–7 cm, apex acute

or acuminate, base acute, membranaceous to chartaceous, glabrous; secondary veins 6–16 each side, tertiary venation reticulate; petioles 5–20 mm long, glabrous. **Inflorescences** pedunculate, paniculate, multiflorous, 6–9 × 4.5–9 cm, rachis usually filiform, red; peduncles 1.5–4 cm long, glabrous; leaves subtending the inflorescence smaller than those of lower nodes; **bracts** subtending the secondary branches narrowly triangular to lanceolate, 4–7 × 1–2 mm long; **bracteoles** 1 or 2 (rarely 3) each flower, triangular, 2–3 mm long, or rarely absent. **Flower buds** ovoid at apex. **Pedicels** absent or 2–4 mm long. **Flowers** sessile or short-pedicellate, fragrant. **Calyx** 0.7–1 mm long; lobes triangular, glabrous. **Corolla** 9–12 mm long, cream-white; tube 6–8.5 × 0.7–0.9 mm, glabrous outside, sparsely pubescent inside; lobes oblong, 2–3.5 × 1.7–2.5(–3.5) mm, apex round (rarely microscopically apiculate), glabrous. **Stamens** 1.6–1.9 mm long; anthers narrowly oblong, 1.5–1.8 mm long, apex apiculate. **Style** 8.5–13 mm long; style branches ovate, ca. 1 mm long. **Fruit** subglobose, didymous, 5–7 × 4–6 mm, glabrous, red to blackish.

Selected specimens examined: **BRAZIL. Paraná:** Mun. Guaraqueçaba, Rio Murato, 11 Dec 1970 (fl), *G. Hatschbach 25807* (UB). **Rio de Janeiro:** Taquara da Tijuca, 1 Nov 1972 (fl), *D. A common species occurring in the states of Rio de Janeiro, São Paulo and Paraná, distinguishable by its leaf blades membranaceous to chartaceous, with tertiary (subsecondary) veins parallel to the secondary veins, inflorescences pauciflorous and with delicate-thin rachis (often filiform), and flower buds narrowly-tubular at base and ovoid at apex.

The names *Ixora heterodoxa*, *I. dimorphophylla* and *I. burchelliana* are synonymous and have equal priority because they were published in the same article by Müller Argoviensis (1875). The name *I. heterodoxa* is chosen over the others because its holotype is a complete specimen with flowers in bud and in anthesis, while the holotype of *I. burchelliana* (G-DC) is only represented by a leaf fragment. No type specimens of *I. dimorphophylla* are present at G-DC, and its holotype is at C, as it was indicated by Müller Argoviensis (1875).

Ixora syringiflora (Schltdl.) Muell. Arg., Flora 58:455. 1875. *Psychotria syringaeflora* Schltdl., Linnaea 28: 516. 1856. TYPE: BRAZIL [Bahia?]: locality unknown, s.d. [1828–1856], *Blanchet 3348* (HOLOTYPE: B†, photo at NY!).

Ixora benthamiana Muell. Arg., **syn. nov.**, Flora 58:455, 459. 1875. TYPE: BRAZIL. RIO DE JANEIRO: Rio São João, s.d. [1817–1820], *Pohl 2209* (LECTOTYPE, G-DC n.v., here selected, photo at NY!).

Tree to 10 m tall; branchlets glabrous. **Stipules** 4–6 × 2.5–3.5 mm, base deltoid, arista 3–4 mm long, glabrous outside, densely sericeous-pubescent and intermixed with colleters inside. **Leaf** blades elliptic, oblong-ovate, to narrowly obovate, 5.5–21 × 3–6.5 cm, apex acute, commonly deltoid-acuminate, base acute, membranaceous to chartaceous, glabrous; secondary veins 16–34 each side, tertiary venation reticulate; petioles 5–20 mm long, glabrous. **Inflorescences** pedunculate, paniculate, multiflorous, 10–14 × 10–14 cm, with 4–5 lateral branches laxely paniculate; peduncles 1.5–4 cm long, glabrous; leaves subtending the inflorescence smaller than those of lower nodes; **bracts** subtending the secondary branches narrowly triangular to narrowly elliptic, 6–15 × 1–4 mm long; **bracteoles** 1 or 2 each flower, ovate to oblong, 0.7–1 mm long, or rarely absent. **Flower buds** oblong-ellipsoid at apex. **Pedicels** absent or 2–5 mm long. **Flowers** sessile or short-pedicellate, fragrant. **Calyx** 0.7–1 mm long; lobes triangular or ovate, glabrous. **Corolla** 6.5–7.5 mm long, cream-white; tube 2–2.9 × 0.8–1 mm, glabrous outside, sparsely pubescent at distal portion inside; lobes oblong, 3.8–4.6 × 1.5–1.8 mm, apex round, glabrous. **Stamens** ca. 4.5 mm long; anthers narrowly oblong, ca. 3 mm long, apex apiculate. **Style** 6.5–8.5 mm long; style branches narrowly oblong, 1.5–2 mm long. **Fruit** unknown.

Illustration.—Mart., Fl. Bras. 6(5), Tab. 10. 1881 (as *Ixora benthamiana*).

Additional specimens examined. **BRAZIL. São Paulo:** Mun. São Paulo, Fda. Itatuba, 23 Dec 1931 (fl), *Amaral s.n. (SP 28628)* (K, MO, NY, SP); Mun. Porto Ferreira, Reserva Estadual de Porto Ferreira, 2 Dec 1981 (fl), *Bertoni s.n. (UEC 16894)* (NY, UEC); Mun. Campinas, Reserva Municipal de Santa Genebra, 7 Nov 1988 (fl), *Leitão Filho & Morellato s.n. (UEC 22901)* (UEC).

This species easily recognized by its laxely paniculate, many-branched, multiflorous inflorescences. It is a very rare, or probably extinct, species known only from four historical collections from the states of Rio de Janeiro and São Paulo (and probably Bahia, *Blanchet 3348*, the type specimen).

Ixora venulosa Benth., Linnaea 23:446. 1850. TYPE: BRAZIL. MINAS GERAIS: Caldas, s.d. [1841–1874], *Regnell I.275b* (LECTOTYPE, K!, here selected, photo at NY!).

Shrub to 5 m tall or rarely **tree** to 9 m tall; bark rugose; branchlets glabrous. **Stipules** 4–8 × 3–4 mm, base narrowly triangular to oblong, arista 1–3 mm long, glabrous outside, densely sericeous-pubescent and intermixed with colleters inside. **Leaf** blades narrowly elliptic, oblong-elliptic, narrowly obovate to obovate, (1.5–)4–14 × 1–6 cm, apex acute, often acuminate, base acute or decurrent, chartaceous to subcoriaceous, glabrous; secondary veins fine and dense, 30–60 each side, tertiary venation subparallel to the secondary (sometimes somewhat

reticulate); petioles 2–15 mm long, glabrous. **Inflorescences** pedunculate, paniculate, pauciflorous, 2–8 × 1.5–6 cm, with 1 or 2 lateral branches, these sparsely branched; peduncles 1–6 cm long, glabrous; **bracts** subtending the secondary branches narrowly triangular, 7–10 × ca. 1 mm long, to narrowly elliptic, 10–13 × 3–5 mm; **bracteoles** 1 or 2 each flower, narrowly oblong-triangular, or absent. **Flower buds** ovoid at apex. **Pedicels** absent or to 2 mm long. **Flowers** sessile or short-pedicellate, fragrant. **Calyx** 0.3–1.2 mm long; lobes triangular or ovate, glabrous. **Corolla** 8.5–10.5 mm long, cream-white; tube 4.5–6.5 × 0.7–0.9 mm, glabrous outside, sparsely sericeous-pubescent inside; lobes oblong-ovate, 3.5–3.8 × 1.5–2.2 mm, apex round, glabrous, sometimes with undulate margin. **Stamens** 3.5–4 mm long; anthers narrowly oblong, 2.5–3 mm long, apex apiculate. **Style** 6.5–8.5 mm long; style branches oblong, 1.3–1.7 mm long. **Fruit** globose, 5–6.5 mm in diam., glabrous, red.

A species readily distinguishable for the leaf blades with fine, dense venation (30–60 secondary veins each side), common in the moist Atlantic forests of the Brazilian states of Rio de Janeiro, São Paulo, Paraná, and Santa Catarina, and in the gallery forests of the cerrado biome of Minas Gerais, and occasionally found in Paraguay.

KEY TO THE NATIVE SPECIES OF *IXORA* OF THE STATE OF SÃO PAULO, BRAZIL

1. Leaf blade with dense, equal secondary venation (30–60 each side); tertiary veins dense and parallel to the secondary veins _____ **I. venulosa**
1. Leaf blade with sparse, unequal secondary venation (6–40 each side); tertiary veins subreticulate.
   2. Corolla lobes shorter than the tube; flower buds ovoid at apex.
      3. Corolla tube 6–8.5 mm long, lobes 2–3.5 mm long; stipules 5–6 × 2.5–3.5 mm, with an arista 2–3.5 mm long _____ **I. heterodoxa**
      3. Corolla tube 4.5–5.5 mm long, lobes 3.5–4 mm long; stipules 2.5–3.5 × 1.5 2 mm, with an arista 1.5 mm long _____ **I. gardneriana**
   2. Corolla lobes longer than the tube; flower buds oblong-ellipsoid at apex.
      4. Inflorescence 10–14 cm in diam., with 4–5 secondary branches, these densely branched and laxely paniculate _____ **I. syringiflora**
      4. Inflorescence 3–8(–10) cm in diam., with 2–3 secondary branches, these sparsely branched and corymbiform _____ **I. brevifolia**

ACKNOWLEDGMENTS

I am extremely grateful to Sigrid Jung-Mendaçolli (IAC), coordinator of the Rubiaceae treatment for the *Flora Fanerogamica do Estado de São Paulo*, for inviting me to contribute *Ixora* for the flora, for her productive collaboration, and for arranging the loans of *Ixora* from the herbaria of the state of São Paulo to the NY herbarium. I am also much indebted to the Conselho Nacional de Pesquisa e Desenvolvimento Científico e Tecnológico (CNPq), Brazilian Govern-

ment, for granting permission to perform field and herbarium work in the states of Goiás and Santa Catarina, during 1998–2000. I also wish to thank the directors and curators of the following herbaria for sending material on loan and for facilitating the access to their collections: BR, C, ESA, FLOR, HBR, HRCB, IAC, K, MO, NY, S, SP, SPSF, UB, UFG, UEC, UPCB, UPS and US. My sincere gratitude goes to the staff of the G-DC herbarium for producing and sending the 80 black and white negatives of *Ixora* types, and to The New York Botanical Garden for printing the photos used in this study. I also wish to thank the staff of the Kew herbarium (K), Jochen Heinrichs (GOET), and Arne Anderberg (S) for searching for the type specimens of *Ixora brevifolia* in their institutions. I am particularly grateful to Roland Moberg, Curator of the UPS herbarium, for sending the type specimen of *Ixora brevifolia* on loan to NY, and for additional information. Special thanks are also due to Claes Persson (GB) and Petra de Block (BR) for the constructive comments on the manuscript.

ABSTRACT

A new section of *Baccharis* is described: sect. *Punctatae*, including six species formerly placed in sect. *Aristidentes* (*B. bigelovii*, *B. crassicuneata*, *B. mexicana*, *B. sulcata*, *B. thesioides*, and *B. zamoranensis*). *Baccharis palmeri* is excluded from sect. *Aristidentes* while the South American *B. hirta* is added. Six species (*B. auriculigera*, *B. huairacajensis*, *B. klattii*, *B. maxima*, *B. volubilis*, and *B. zumbadorensis*) are added to sect. *Tubulatae*. A key is provided to differentiate these allied sections, as well as the related sect. *Bogotenses*.

RESUMEN

Se describe una nueva sección de *Baccharis*: sect. *Punctatae*, la cual incluye seis especies previamente ubicadas en la sección *Aristidentes* (*B. bigelovii*, *B. crassicuneata*, *B. mexicana*, *B. sulcata*, *B. thesioides* y *B. zamoranensis*). *Baccharis palmeri* es excluida de la sección *Aristidentes*, mientras que la especie sudamericana *B. hirta* es agregada a ella. Seis especies (*B. auriculigera*, *B. huairacajensis*, *B. klattii*, *B. maxima*, *B. volubilis* y *B. zumbadorensis*) son agregadas a la sección *Tubulatae*. Se provee una clave para diferenciar estas secciones afines, incluyendo asimismo la sección *Bogotenses*.

In a revision of the infrageneric taxonomy of North and Central American species of *Baccharis*, Nesom (1990) proposed the section *Aristidentes* to include 12 species. Later, the same author (Nesom 1998) recognized two informal groups within this section: the "*Baccharis multiflora* complex", including 6 species (*B. brevipappa* (McVaugh) G.L. Nesom, *B. mexicana* Cuatrec., *B. multiflora* Kunth – the type species of the section–, *B. serrifolia* DC., *B. sordescens* DC., and *B. zamoranensis* Rzed.), and the "*Baccharis thesioides* complex", comprising 3 species (*B. bigelovii* A. Gray, *B. sulcata* DC., and *B. thesioides* Kunth). With further observation, the differences between these two groups have proved to be more significant, especially when two closely related South American taxa, sect. *Bogotenses* Cuatrec. and sect. *Tubulatae* Cuatrec., are also considered. Effectively, the "*B. multiflora* group" shares more features with these South American taxa than with the "*B. thesioides* group" (see key below); therefore, this taxon is here given formal recognition at sectional rank, as follows.

Baccharis sect. **Punctatae** Giuliano & G.L. Nesom, sect. nov. TYPE: *Baccharis bigelovii* A. Gray.

Sectioni *Aristidenti* similis, sed plantis glutinosis nidis pilosis vestitis, foliis uni- vel obscure trinervatis et achaeniis minoribus differt.

Erect shrubs or subshrubs, glutinous, covered by minute tufts of (microscopic) biseriate glandular hairs; on both leaf surfaces, each tuft is placed in a depression of circular contour, altogether forming a characteristic dotted pattern. Leaves pseudopetiolate, uni- or trinervate, margins aristate-serrate (rarely entire). Capitula pedicellate, arranged in simple or compound corymbs, altogether forming a false panicle. Involucres campanulate. Receptacles flat or slightly convex, alveolate, epaleate. Ratio of carpellate: staminate florets ca. 1:1. Carpellate corollas filiform, apically truncate and crowned by long and short biseriate hairs. Achenes terete, 1.2–2.2 mm long, 5–8-ribbed, glabrous or with few uniseriate hairs with apiculate terminal cell; pappus bristles in 1–2 series, persistent, slightly accrescent. Staminate corollas campanulate, 5-lobed at apex; style branches lanceolate, free; pappus bristles apically broadened.

Includes 6 species, distributed from the southwestern United States to southern Mexico.

1. **B. bigelovii** A. Gray, Rep. U.S. Mex. Bound., Bot. 84. 1859.
2. **B. crassicuneata** G.L. Nesom, Phytologia 84:43. 1998.
3. **B. mexicana** Cuatrec., Brittonia 12:195. 1960.
4. **B. sulcata** DC., Prodr. 5:419. 1836.
5. **B. thesioides** Kunth, in Humboldt, Bonpland & Kunth, Nov. gen. sp. 4 [quarto]: 61. 1820.
6. **B. zamoranensis** Rzed., Brittonia 24:400. 1972.

Formerly, *B. mexicana* and *B. zamoranensis* were included in the "*B. multiflora* complex" of sect. *Aristidentes* (Nesom 1998) but now are classified within *Punctatae*, as they are glutinous plants dotted with tufted hairs.

Section *Punctatae* is closely related to sect. *Aristidentes*, sect. *Bogotenses* and sect. *Tubulatae*; the four taxa form a complex characterized by the capitulescence architecture (a false panicle of compound corymbs), achenes with 5–8 pale ribs, glabrous or with few uniseriated hairs, and pappus with persistent accrescent bristles in 2–3 series. These sections can be differentiated by the following features:

1. Plants glutinous, dotted by minute (microscopic) tufts of glandular hairs, without other vestiture. Leaves uni- or obscurely trinervate. Achenes 1.2–2.2 mm long. _____ Sect. **Punctatae**
1. Plants non-glutinous, non dotted by minute hair tufts but densely or loosely clothed by conspicuous (non-microscopic), non-glandular uniseriate hairs with acuminate terminal cell, often incurved. Leaves usually reticulate-nervate, trinervate in some species. Achenes 2.5–4 mm long.
   2. Scandent shrubs, densely pubescent, with long uniseriate conic hairs accompanying the uniseriate hairs with acuminate terminal cell. Capitula often grouped in few-headed inflorescences; carpellate involucres 7-9 mm long. Staminate florets with tubulose elongate limb and short straight lobes _____ Sect. **Tubulatae**
   2. Scandent or erect shrubs, without conic hairs but densely or loosely clothed by

uniseriate hairs with acuminate terminal cell. Capitula usually grouped in many-headed inflorescences; carpellate involucres 3 -6 mm long. Staminate florets with short limb and developed recurved lobes.

3. Scandent shrubs, subglabrous, with few isolated hairs. _____ Sect. **Bogotenses**
3. Erect shrubs, densely pubescent. _____ Sect. **Aristidentes**

The following couplet provides a summary of the contrasts between sect. *Punctatae* and the taxon from which it was segregated, sect. *Aristidentes*:

1. Plants glutinous, dotted by minute tufts of (microscopic) glandular hairs, without other vestiture. Leaves uni- or obscurely trinervate. Achenes 1.2–2.2 mm long. _____ Sect. **Punctatae**
1. Plants non-glutinous, non dotted by minute hair tufts but densely clothed by conspicuous (non-microscopic), non-glandular uniseriate hairs with acuminate terminal cell, often incurved. Leaves usually reticulate-nervate, trinervate in some species. Achenes usually 2.5–3 mm long. _____ Sect. **Aristidentes**

Further notes on sect. *Aristidentes*

Several of the species originally included in sect. *Aristidentes* are here relocated to the new section *Punctatae*. *Baccharis palmeri* Greenm. is also here excluded from sect. *Aristidentes* since it lacks the pubescence characteristic of this taxon, and it is placed in sect. *Angustifoliae* Baker emend. Cuatrec., considering that it produces solitary capitula at the apex of the branches, which often are grouped to form false capitulescences.

On the other hand, one species needs to be added to sect. *Aristidentes*, since it presents its typical features: *B. hirta* DC., from southern Brazil and Uruguay. This species was previously classified in the formerly heterogeneous sections *Trinervatae* DC. (Candolle 1836), *Cuneifoliae* DC. (Hooker & Arnott 1841), *Oblongifoliae* DC. (Baker 1882) and *Paniculatae* Heering (Heering 1904). With the 4 South American species added to sect. *Aristidentes* by Giuliano (2001), the number of species for the section becomes 11: *B. brevipappa* (McVaugh) G.L. Nesom, *B. hirta* DC., *B. lilloi* Heering, *B. malibuensis* R.M. Beauch. & Henrickson, *B. multiflora* Kunth, *B. plummerae* A. Gray, *B. polygama* Ariza, *B. pulchella* Sch. Bip. ex Griseb., *B. racemosa* (Ruiz & Pav.) DC., *B. serrifolia* DC., and *B. sordescens* DC.

Addition of species into sect. *Tubulatae*

Section *Tubulatae* was founded by Cuatrecasas (1967), who included 3 Andean species (*B. fraterna* Cuatrec., *B. granadina* Cuatrec., and *B. grandiflora* Kunth). Here it is considered necessary to add 5 species more, as they accord with the diagnostic features of this taxon: the Andean *B. auriculigera* Hieron. (previously placed into sect. *Trinervatae*; Hieronymus 1905), *B. huairacajensis* Hieron. (placed in sect. *Oblongifoliae* when originally described; Hieronymus 1901), *B. klattii* Benoist (never classified before), *B. volubilis* Kunth (formerly in sect. *Oblongifoliae*; Candolle 1836), and *B. maxima* Baker, endemic of the state of Rio de Janeiro in Brazil (placed in sect. *Oblongifoliae* when described; Baker 1882).

Another species, the Venezuelan endemic *B. zumbadorensis* V.M. Badillo, is

also placed here although staminate specimens are still unknown, since it has scandent habit, long conic hairs, reticulate-nerved leaves, large few-headed capitula, and large achenes, which fit properly in *Tubulatae*. The nine species of this section are mainly Andean in distribution.

ACKNOWLEDGMENTS

We are grateful to Scott Sundberg for his insightful and researched review of the manuscript. This study was carried out partly (D.A.G.) by means of a fellowship ("Beca de Formación de Postgrado") conceded by the Consejo Nacional de Investigaciones Científicas y Técnicas de la República Argentina (CONICET).

ABSTRACT

Gentianella boliviana and *G. inaequicalyx* are recognized as species and the nomenclatural combinations are validated.

RESUMEN

Se reconocen como especies *Gentianella boliviana* y *G. inaequicalyx*, y se validan las combinaciones nomenclaturales.

Two new combinations are required for identifications and for use in the *Catalogue of the Vascular Plants of Bolivia*, in progress at the time of this writing, edited by Peter Møller Jørgensen.

GENTIANELLA BOLIVIANA

Gentiana boliviana Pax, *G. hieronymi* Gilg, *G. lobelioides* Gilg, and *G. peruviana* (Griseb.) Gilg, which had been recognized as four species by Gilg (1916), were treated by Ho and Liu (1993) as a single species, which they called *Gentianella peruviana* (Griseb.) Fabris. Nomenclaturally, this treatment is incorrect. The name *Gentianella peruviana* (Griseb.) Fabris was based on *Gentiana limoselloides* [var.] β *peruviana* Griseb. The name *Gentiana peruviana* (Griseb.) Griseb. was based on this varietal name as to the basionym but not as to the plants described. When it was published in 1879, it was an illegitimate homonym of *Gentiana peruviana* Lam. 1786, which is a taxonomic synonym of *Centaurium cachanlahuen* (Molina) B.L. Rob. The name *Gentiana peruviana* (Griseb.) Gilg 1896 was based on *G. limoselloides* [var.] β *peruviana* Griseb. both as to basionym and as to plants described, but by typification was a superfluous combination. It likewise is illegitimate. There was no obstacle to the use of the epithet *peruviana* in *Gentianella* by Fabris (1958), but, as he recognized, the priority of the epithet *peruviana* at the rank of species, as applied to any of the *Gentianella* taxa discussed here, dates only from its use in this legitimate combination in 1958. The epithets *hieronymi*, *boliviana*, and *lobelioides* have priority at the rank of species in this context dating from their publication in

[1]Contribution No. 117 from the Royal Botanical Gardens, Hamilton, Ontario, Canada.

legitimate combinations in 1896, 1909, and 1916, respectively. Therefore, if the four taxa recognized by Gilg in 1916 are treated as conspecific, the correct name for the species thus circumscribed is *Gentianella hieronymi* (Gilg) Fabris. The name *Gentianella peruviana* (Griseb.) Fabris is correct only when the species to which it is applied is more narrowly defined, as it was by Fabris.

Within *G. peruviana*, Ho and Liu (1993) recognized two varieties: var. *peruviana*, in which they included *G. hieronymi* of Gilg (1916); and var. *boliviana* (Pax) T.N. Ho, which was equivalent to *Gentiana boliviana* plus *G. lobelioides* of Gilg (1916). Having studied nomenclaturally significant material of both taxa, I have chosen to recognize *G. boliviana* as a species rather than to consider it conspecific with *Gentianella hieronymi*.

Gentianella boliviana (Pax) J.S. Pringle, comb. nov. BASIONYM: *Gentiana boliviana* Pax, Repert. Spec. Nov. Regni Veg. 7: 243. 1909. *Gentianella peruviana* (Griseb.) Fabris var. *boliviana* (Pax) T.N. Ho, Bull. Nat. Hist. Mus. London, Bot. 23:64. 1993. TYPE: BOLIVIA. LA PAZ: Chacaltaya, 30 km from La Paz, 4800 m, *Buchtien 1482* (HOLOTYPE: B, destroyed; ISOTYPE: US, microfiche MO!).

Gentianella boliviana was further represented in my studies by *Beck 7477* and *8022* (HAM, [LPB]), *Menhofer X-2312* (HAM, [LPB]), *Solomon 5066* (MO), *Solomon & Moraes R. 13462* (MO), and *Ruthsatz 1057* and *1105* (both HAM). (Brackets indicate replicates not seen by me.) All of these specimens were collected near the type locality in Depto. La Paz.

Gentianella hieronymi is native to Provs. Jujuy and Salta, Argentina. The type collection is *Hieronymus & Lorentz 15* (HOLOTYPE: B, destroyed, photo F!; ISOTYPES: CORD, K!). It and *G. boliviana* are well separated geographically.

Gentianella boliviana and *G. hieronymi* differ as indicated in the following descriptions:

Gentianella boliviana (Pax) J.S. Pringle. Herbaceous perennial, 1–4 cm (including peduncles and flowers). Flowering stems usually only 1 or 2, occasionally to 6, decumbent, unbranched. Leaves all basal or cauline leaves 1 pair, all leaves narrowly obovate to linear-oblanceolate, 4–10(–16) × 1–4 mm, rounded or obtuse. Flowers solitary; peduncles 1–3 cm. Calyx 5–8 mm, lobed 0.45–0.55× its length, lobes narrowly obovate to oblong, rounded to obtuse or occasionally subacute. Corolla light blue with darker veins, widely campanulate, 10–16 mm, lobed 0.54–0.65× its length, lobes oblong-obovate, rounded at apex.

Gentianella hieronymi (Gilg) Fabris. Herbaceous perennial (?), 2–7 cm (including peduncles and flowers). Flowering stems usually 5–12, decumbent, unbranched. Basal leaves narrowly obovate to oblanceolate, 8–12 × 2–4 mm, obtuse; cauline leaves usually none, occasionally or 1 or 2 pairs, elliptic to linear, 6–10 × 1–2 mm, obtuse. Flowers solitary; peduncles 1–4 cm. Calyx 8–14 mm, lobed 0.45–0.65× its length, lobes oblong, rounded at apex. Corolla pale lilac, campanulate, 18–25 mm, lobed 0.52–0.60× its length, lobes elliptic-obovate, subacute.

Among the several low-growing, solitary-flowered species of *Gentianella* native to Depto. La Paz, *G. boliviana* is especially distinctive. The plants of this species are generally smaller than those of any other *Gentianella* species in La Paz. Its distinctive features include calyx lobes about as long as the tube, usually rounded at the apex, and corollas 10–16 mm long, with widely spreading lobes slightly longer than the tube, widely rounded at the apex ("obtusissimus" in the original description). The corollas of both of the specimens at MO were described as "pale blue" and those of *Beck 8022* as "verde-azul pálida." In herbarium specimens, this color, when well preserved, is reminiscent of that of *Amsonia tabernaemontana* Walter of North America, and is an instant guide to the recognition of *G. boliviana*. In the other solitary-flowered *Gentianella* species in Depto. La Paz the corollas are predominantly white, in most cases marked with dark blue-violet.

Gentianella hieronymi, which is not native to Bolivia, differs most conspicuously from *G. boliviana* in its larger, more floriferous plants; more narrowly campanulate calyces; larger, pale lilac, less widely opening corollas; and proportionately narrower corolla lobes that are subacute at the apex.

Many low-growing species of *Gentianella* with solitary- or few-flowered stems are present in Argentina, Bolivia and Peru, and not all of the taxonomic questions pertaining to these species can be resolved within a single paper. *Gentiana lobelioides*, now called *Gentianella lobelioides* (Gilg) Zarucchi, is known only from the type specimen, *Weberbauer 955* (holotype B, destroyed, photo F!), from Depto. Puno, Peru, directly across the border from Depto. La Paz, Bolivia. From my study of published descriptions and a photograph of the type its inclusion within *G. boliviana* seems reasonable. Notably, the corollas were described as "pallide-coerulei" (Gilg 1916), and those of the type specimen appear to have been ca. 11 mm long. However, since the type was in poor condition when photographed and I have encountered no specimens from Peru referable to *G. lobelioides*, its disposition is not within the scope of this paper. With *G. boliviana* (and probably *G. lobelioides*) excluded, populations referable, respectively, to *G. hieronymi* s. str. in Argentina and *G. peruviana* s. str. in Depto. Cuzco, Peru, are widely separated. These species were considered distinct by Fabris (1958), who emphasized differences in the proportionate lengths of the calyx lobes and tube as well as in corolla size. From descriptions (Gilg 1916; Fabris 1953, 1958) and photographs of the type specimens their recognition as separate species seems tenable, but since I have not seen specimens referable to *G. peruviana* s. str., further discussion of that species is not included here.

GENTIANELLA INAEQUICALYX

Ho and Liu (1993) included five species recognized by Gilg (1916) within their circumscription of *Gentianella silenoides* (Gilg) Fabris. They treated this species as comprising three varieties: var. *silenoides*, equivalent only to *Gentiana*

silenoides of Gilg (1916); var. *striaticalyx* (Gilg) T.N. Ho, within which they included *Gentiana striaticalyx* Gilg, *G. anthosphaera* Gilg, and *G. herzogii* Gilg; and var. *inaequicalyx* (Gilg) T.N. Ho, based on *Gentiana inaequicalyx* Gilg. The epithets *silenoides* and *inaequicalyx* both have priority at species rank dating from 1896, the other epithets from 1906 or 1916. Ho and Liu indicated that they had seen no specimens relevant to the typification of the epithets *silenoides*, *striaticalyx*, and *herzogii*, and cited no specimens that would exemplify their concepts of these taxa. They had seen isotypes of the names *Gentiana anthosphaera* and *G. inaequicalyx*.

I have examined photographs of the type specimens of all five of these epithets, as well as isotypes, paratypes, and more recent specimens from sites near the respective type localities that corresponded closely to the respective type specimens. My studies have in part supported Ho and Liu's revision, but have also indicated that some modifications would be appropriate. Specifically, *Gentianella silenoides* s. str. and the taxon treated here as *G. inaequicalyx* are distinctly dissimilar and conform well to standards for the recognition of species in South American *Gentianella*.

Gentianella inaequicalyx (Gilg) Fabris ex J.S. Pringle, comb. nov. BASIONYM: *Gentiana inaequicalyx* Gilg, Bot. Jahrb. Syst. 22:324. 1896. *Gentianella silenoides* (Gilg) Fabris var. *inaequicalyx* (Gilg) T.N. Ho, Bull. Nat. Hist. Mus. London, Bot. 23:64. 1993. TYPE: BOLIVIA. LA PAZ: Vicinis Sorata, 2650–3000 m, *Mandon 365* (LECTOTYPE, here designated, G, photos F!, NY!; ISOTYPES: GH!, K!, NY!, S, US!). PARATYPES: BOLIVIA. COCHABAMBA: Vic. Cochabamba, *Bang 1143* (GH!, K!, NY!); Cochabamba: Tunari, 3000–4000 m, *Kuntze s.n.* (probably B, destroyed).

Gentianella inaequicalyx was further represented in my studies by *Luteyn & Dorr 13799* (HAM, [LPB, NY]), from Depto. La Paz, Bolivia, and *Vargas C. & Cruz G. 4980* (HAM, [NY, USZ]), from Depto. Santa Cruz, Bolivia. Existing data indicate that the range of *G. inaequicalyx* is more northern than that of any of the other entities included in *G. silenoides* s. lat. by Ho and Liu.

The type of the name *G. silenoides* is *Lorentz & Hieronymus 877* (holotype B, destroyed, photo F!), from Depto. Tarija, Bolivia. This species was further represented in my studies by *Bastián 1183* and *1312* (HAM, [LPB]), *Ehrich 199* (HAM, [LPB]), and *Solomon 10197* and *10262* (HAM, [MO]), all from Depto. Tarija, Bolivia. It has also been reported from the adjacent Prov. Salta, Argentina (Fabris 1953).

Gentianella inaequicalyx and *G. silenoides* differ as indicated in the following descriptions:

Gentianella inaequicalyx (Gilg) Fabris ex J.S. Pringle. Herbaceous annual, 6–25 cm. Primary stem usually solitary, erect or curved only at base; branches all ± strongly ascending. Basal and proximal cauline leaves mostly oblanceolate to elliptic, 8–20 × 1–4 mm, obtuse, often absent at flowering time; distal leaves

gradually narrower, lanceolate to linear, 5–30 × 1–5 mm, acute. Inflorescence a dense cyme; flowers sessile or pedicels up to 1 cm. Calyx 6–15 mm, lobed 0.50–0.75× its length, lobes often distinctly unequal, linear, subacute. Corolla white with blue-violet tinge or blue-violet throughout, tubular-campanulate, opening narrowly, 11–22 mm, lobed 0.35–0.45× its length, lobes oblong-ovate, obtuse or abruptly short-acuminate.

Gentianella silenoides (Gilg) Fabris. Herbaceous annual, 8–30 cm. Primary stem usually solitary, erect or ± decumbent; branches widely spreading to ascending. Basal and proximal cauline leaves mostly elliptic, 8–20 × 1–4 mm, obtuse to acute, sometimes absent at flowering time; distal leaves gradually narrower, lanceolate to linear, 7–30 × 1–4 mm, acute. Inflorescence a diffuse cyme; pedicels 1–10 cm. Calyx 9–15 mm, lobed 0.55–0.95× its length, lobes usually subequal, narrowly linear, acute to acuminate. Corolla white to pale blue-violet, narrowly campanulate, opening ± widely, 15–26 mm, lobed 0.45–0.55× its length, lobes elliptic-ovate, acute to acuminate.

Plants of *G. inaequicalyx* are stiffly erect, with dense, many-flowered inflorescences in which the flowers are sessile or on pedicels less than 1 cm long. Its aspect, consequently, is similar to that of the North American *G. quinquefolia* (L.) Small. Its corollas are more narrowly tubular than those of *G. silenoides*, and are proportionately less deeply lobed. *Gentianella silenoides* differs in its diffuse inflorescence with widely separated flowers on pedicels 1–10 cm long, conforming to Gilg's (1916, in the key) description, "Flores in cymas laxas dispositi." Its aspect is consequently similar to that of another Bolivian species, *G. lythroides* (Gilg) Fabris ex T.N. Ho & S.W. Liu, which differs in its more deeply lobed corollas.

The other reductions to synonymy or varietal status within *G. silenoides* by Ho and Liu have been supported by my studies, in particular the reduction of *G. herzogii*. *Solomon 10262*, which, having corollas 28–36 mm long, would be identifiable as *G. herzogii*, and *Solomon 10197*, with corollas 15–18 mm long, in the size range given by Gilg (1916) for *G. silenoides*, were collected at the same locality in Depto. Tarija. They exhibit only modest differences in the size of the plants and in the size of the leaves, peduncles, and flowers, rather than any qualitative differences. The distinction between var. *silenoides* and var. *striaticalyx* (including plants recognized by Gilg both as *Gentiana striaticalyx* and as *G. anthosphaera*), is so slight that even varietal status might be questioned.

Further studies of taxa in this complex would be desirable. *Gentianella pallidolilacina* (Gilg) T.N. Ho & S.W. Liu was accepted as a distinct species by Ho and Liu (1993), but studies of additional material might indicate that it should be included within *G. inaequicalyx*. If these taxa were to be united (exclusive of *G. silenoides*) the epithet *inaequicalyx* would have priority.

BOTANICAL SUMMARY OF A LOWLAND ULTRABASIC FLORA IN PAPUA NEW GUINEA

W. Takeuchi

Harvard University Herbaria and Arnold Arboretum
Research Associate, Village Development Trust
Lae, Morobe Province 411, PAPUA NEW GUINEA

ABSTRACT

The ultrabasic flora of the Kamiali Wildlife Management Area is described from a recent series of floristic surveys. The general account and checklist also incorporates information from earlier collections. Two new species are presented: *Psychotria bulilimontis* (Rubiaceae), and *Trichadenia sasae* (Salicaceae). Other taxa of special interest are briefly discussed.

KEY WORDS: botanical survey, serpentine, ultrabasics

JAPANESE ABSTRACT

カミアリ野生生物管理区の超塩基性植物相について、最近行われた一連の植物調査の結果から記述する。初期に行われたパプア超塩基性ベルト地帯での採集調査結果もモロベ州南部の低地蛇紋岩地域の調査結果と共に総合的に扱った。2つの新種、*Psychotria bulilimontis* (アカネ科)と*Trichadenia sasae* (イイギリ科)について発表するとともに、特に興味深い他の分類群についても簡単に記す。

キーワード：植生調査、蛇紋岩、超塩基性土壌

INTRODUCTION

After more than a century of scientific publication on the Papuasian flora, the ultrabasic (i.e. ultramafic or serpentine) vegetation of Papua New Guinea (PNG) is still largely unknown in spite of its unusual qualities. Multidisciplinary surveys were initiated in 1997 to address the need for information from such areas, using the Kamiali Wildlife Management Area (KWMA) as a focal site for biodiversity assessment (Figs. 1–2). The selected location offered a number of unique advantages among comparable PNG environments, as it included a complete elevational sequence of natural-growth habitats from sealevel to cloudy summits, and its exploration could be conducted with cost-effective itineraries. In the following narrative, botanical results from the recent investigations are presented and integrated with earlier work in the Papuan Ultrabasic Belt.

HISTORICAL BACKGROUND

The first collections from southern Morobe were made in the Waria drainage (Fig. 3) by R. Schlechter (in 1908; see Schlechter 1911–14) after which there was a general neglect of the district until the NGF/LAE collections of the former Department of Forests. Most of Schlechter's specimens were later lost during the WWII destruction of the Berlin Herbarium. In 1990, Clements rediscovered

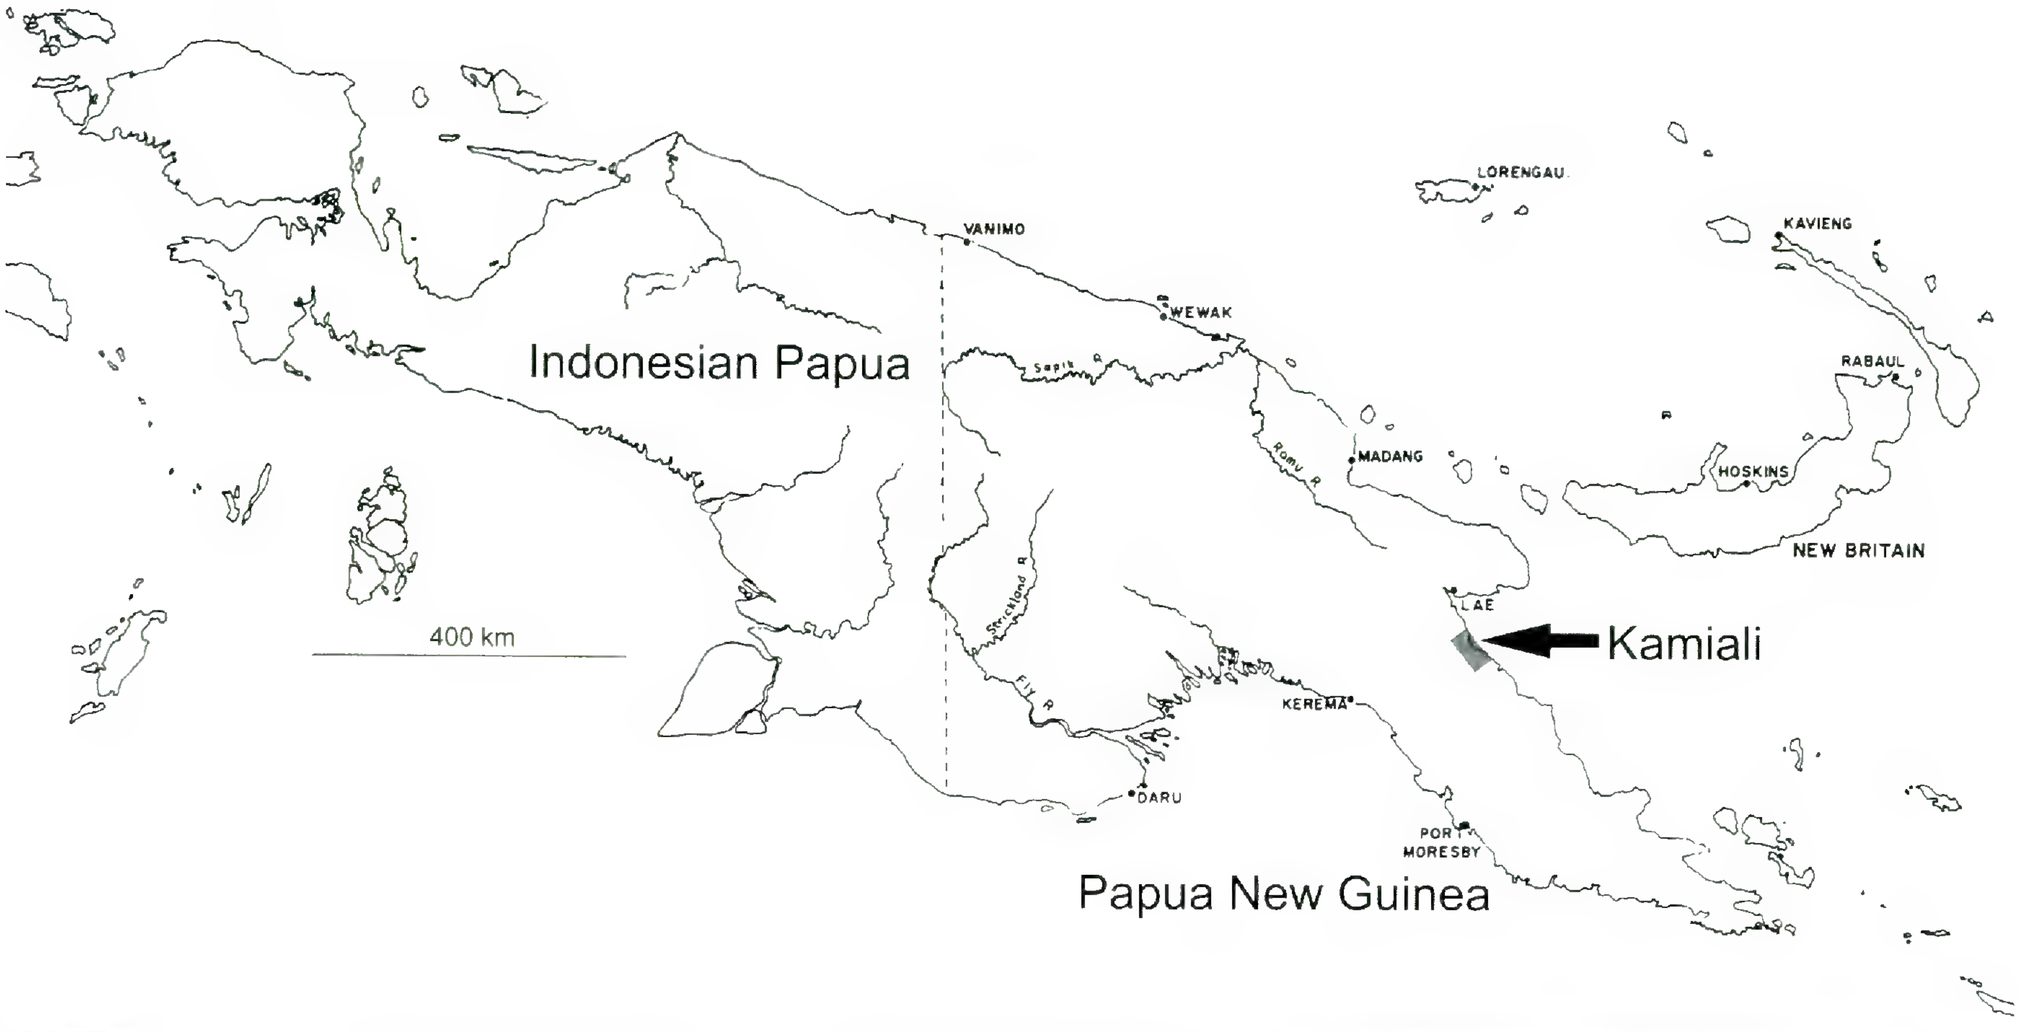

FIG. 1. Island of New Guinea. Shaded area: lowland interval of the Papuan Ultrabasic Belt. Arrow: Kamiali village.

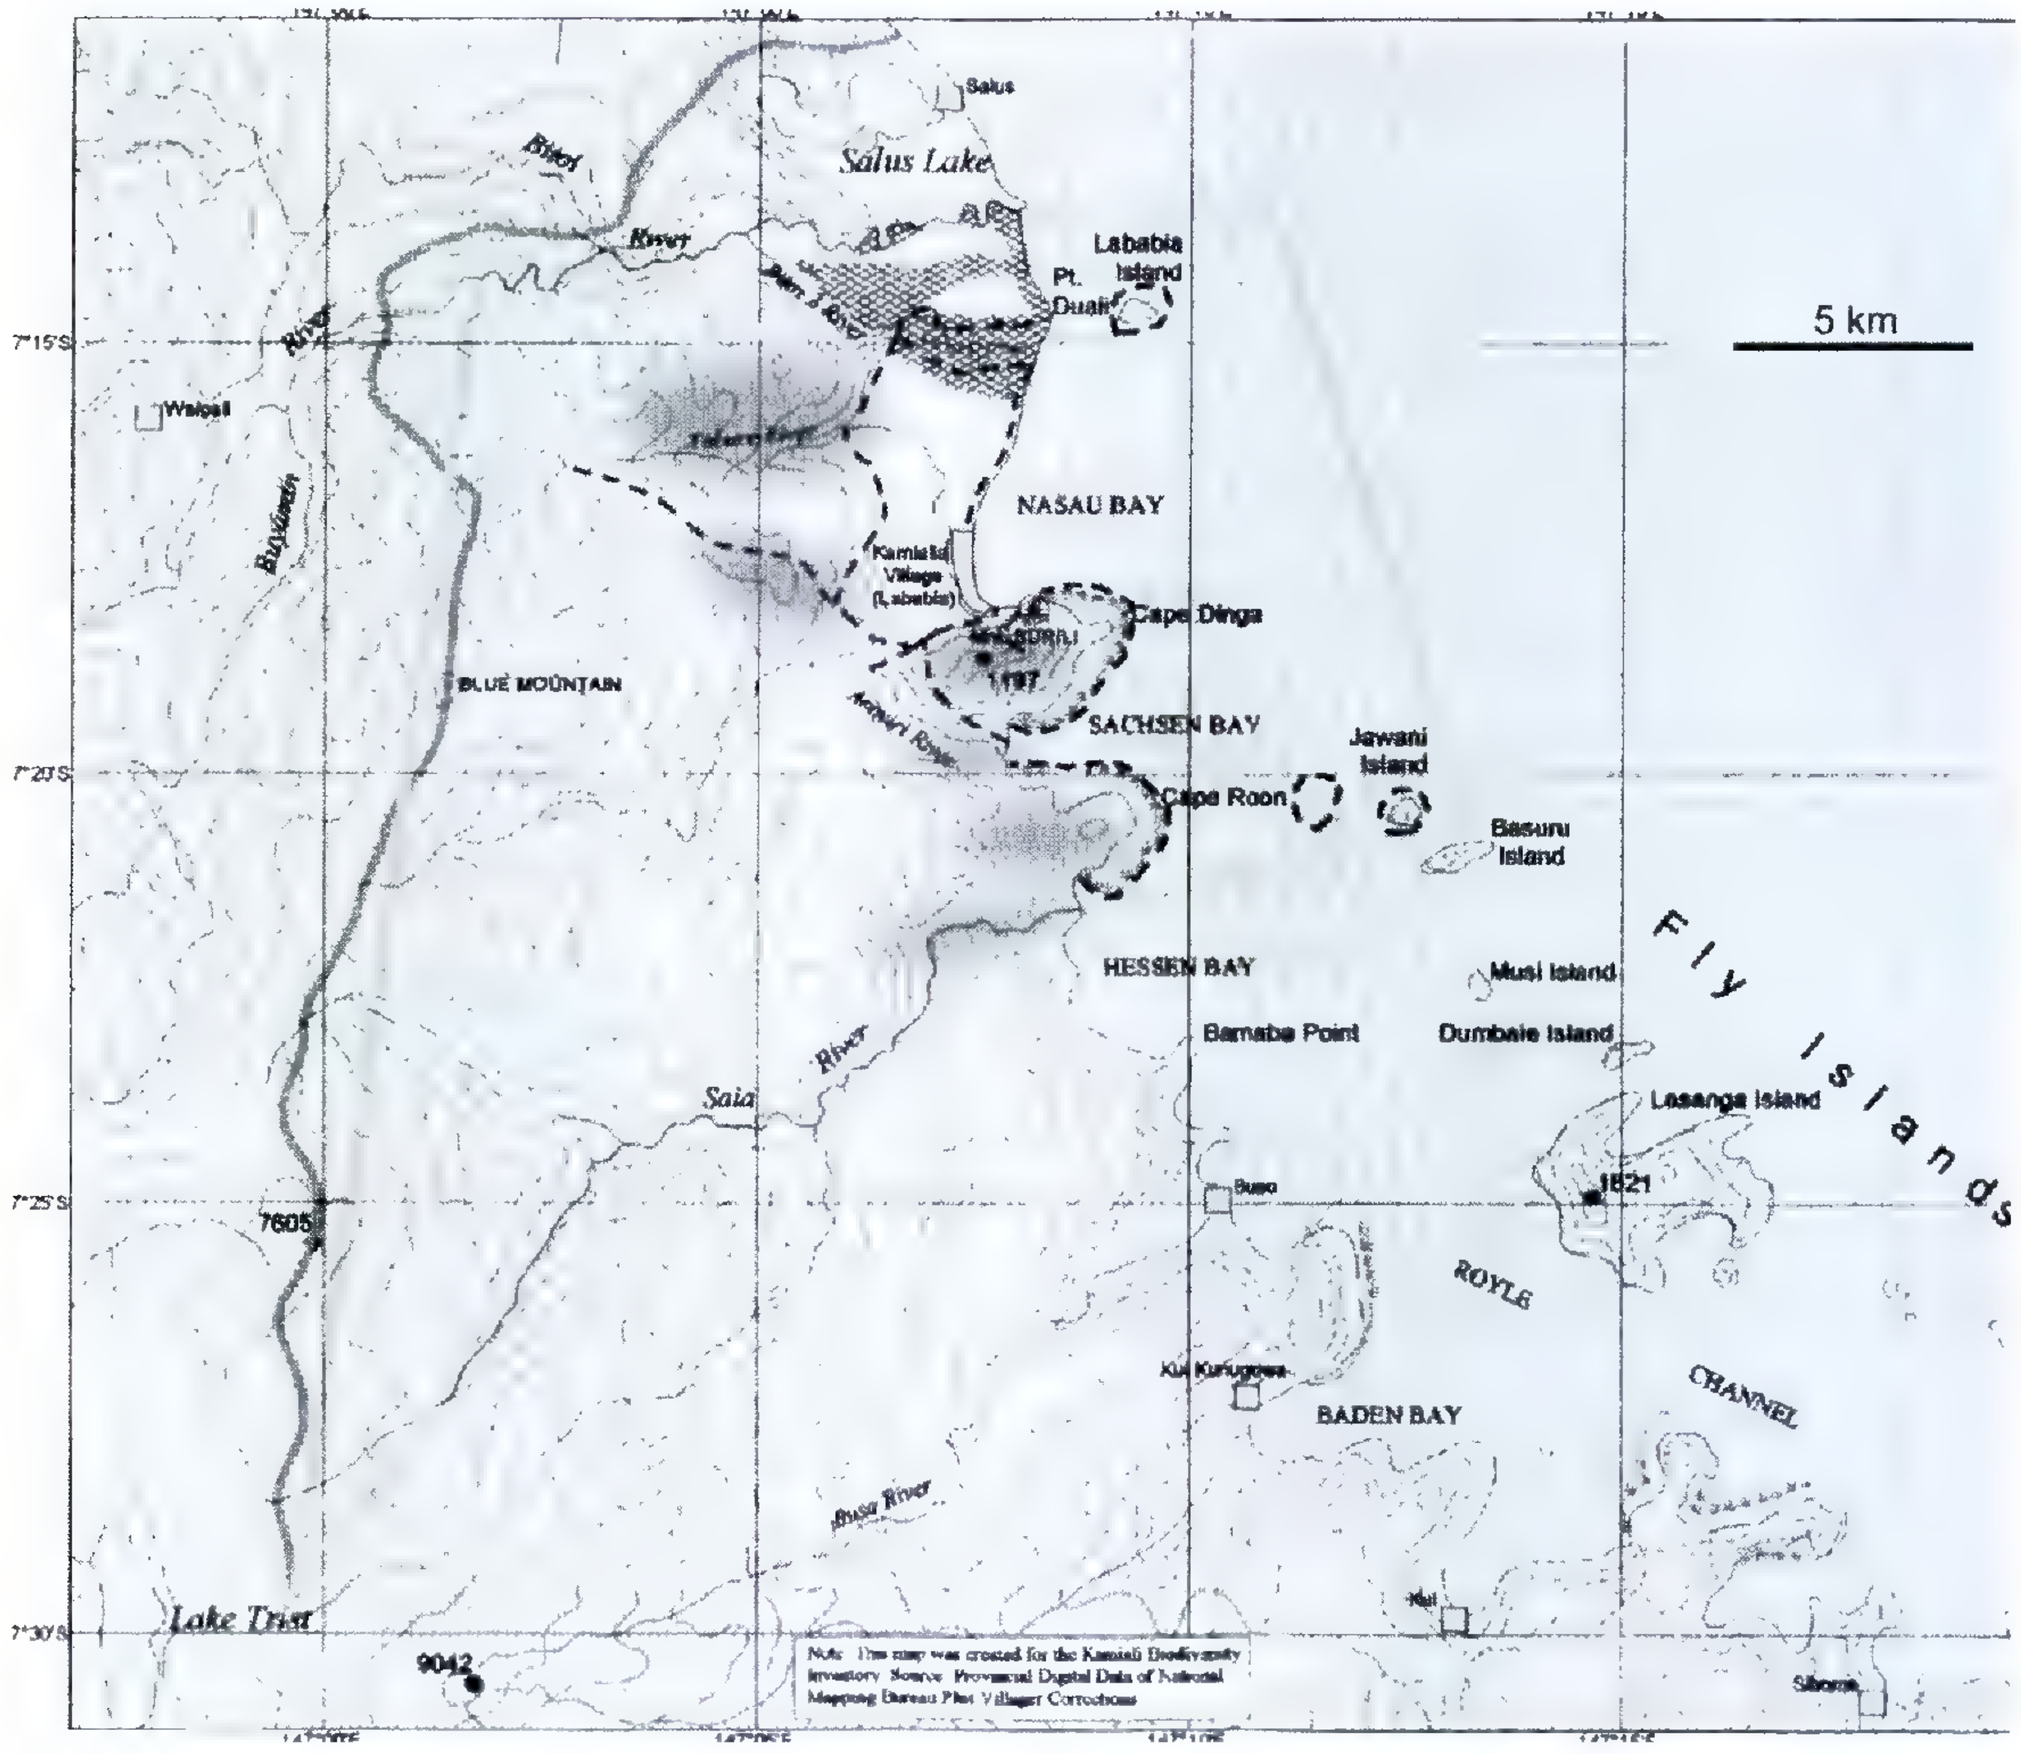

FIG. 2. Kamiali Wildlife Management Area (KWMA). Light-colored perimeter: KWMA gazetted boundary. Darker-colored perimeter: customary lands claimed by the Kamiali people. Shaded elliptical areas: principal survey sites. Contours: 250′, 500′, 1000′, then subsequently in increments of 1000′. Adapted from Village Development Trust file map.

several of the lost German taxa and described some new ones (Clements & Ziesing 1990). Exploration of nearby Natter Bay (e.g. by Croft in 1976) also yielded interesting new material (Fig. 4). Since 1908 there has otherwise been little collections activity between the Waria River and Paiewa (Paiawa).

Particularly during the 1970s, the area around Buso was used as a training site by the Bulolo Forestry College (now Bulolo University) and many specimens were taken during periodic visits by expatriate botanists of that general period (*inter alia* B. Conn, D. Foreman, A. Gillison, E. Henty, M. Jacobs, A. Millar, C. Ridsdale, and H. Streimann). Although the Buso locality is thus relatively well documented in comparison to adjacent areas, it was later despoiled by logging subsidiaries of Rimbunan Hijau. Confronted by mounting environmental concerns from landowners and advocacy groups, the last logging company (Timber Products Marketing Corporation) was forced to leave in 1995, but by

Fig. 3. A typical non-ultrabasic forest in the alluvial zone of the Waria River.

Fig. 4. Natter Bay. Coastal ridges dominated by remnant stands of *Anisoptera thurifera* ssp. *polyandra*.

then an extensive territory between Buso and Morobe Bay had been harvested by commercial operators (Fig. 5).[1] Athough remnant *Anisoptera*-dominant stands are still scattered along the S Morobe coast (e.g. at Siboma or 'Simpoma'), most of the low elevation forests are currently in early successional recovery. The Kamiali Wildlife Management Area (KWMA) is now the only significant primary-growth habitat in the Huon electorate southeast of Lae.

In 1992–1993, the villages of SE Morobe (i.e. Kamiali, Buso, Kui, Siboma, and Paiewa) developed a cooperative proposal for environment-sensitive alternatives to the concessional logging which was then occurring (Zibe-Kokino 1993). Known as the Lasanga Island-Lake Trist Conservation Project, the initiative was based on the principles of Integrated Conservation and Development (ICAD), an economic model which promotes smallscale enterprise as a substitute for ecologically-disruptive activities.

Since its early beginnings at Crater Mt, the ICAD methodology has developed into the principal present-day mechanism for environmental conservation in PNG, as evidenced by the growing body of literature produced by its proponents (e.g. James 1996; Johnson 1997; McCallum & Sekhran 1997; Pearl 1994; Saulei & Ellis 1998; Wagner 2001a, in press). Several major programs are currently being implemented under the ICAD format, most notably by testbed projects in the Adelbert Mts, Crater Mt, Hunstein, Kamiali, Kikori, Milne Bay, and Tonda. However, some conspicuous failures have occurred (McCallum & Sekhran 1997).

Many issues and problems encountered at other ICAD localities were also experienced by the Lasanga-Lake Trist initiative, in particular the inability of stakeholders to achieve a consensus as each clan group fought to maximize its own benefits. After the original design for a 250,000 ha easement was compromised by funding difficulties, the proposal was recast as a 47,000 ha conservation area including only the Kamiali territory (Anon. Sept. 19, 1996). This reduction in scope enabled the project to proceed by focusing participation on a more homogeneous combination of landowners, but at a probable loss in protection of biodiversity values.

The present KWMA is a linked land-sea conservation zone, of which only 29,285 ha is terrestrial environment (ibid.). While there is little consensus on the minimum size requirement for protected areas, it is unlikely that the existing KWMA is large enough to serve as a stand-alone conservation unit. The self-sustainability of biotic communities arguably requires significantly larger territories, especially in view of the destructive effects of probable disturbance

[1]Additional timber production blocks were subsequently proposed by the National Forest Plan (Anon. 1996) for Salamaua, Lake Trist, and Waria Valley. Placed in abeyance by a country-wide forestry moratorium, the prohibitions against new logging projects were recently lifted. However as a result of the logging damage from previous years, it will be difficult for industrial operators to reenter the general area, in part because of the environmental advocacy now conducted by organizations such as VDT.

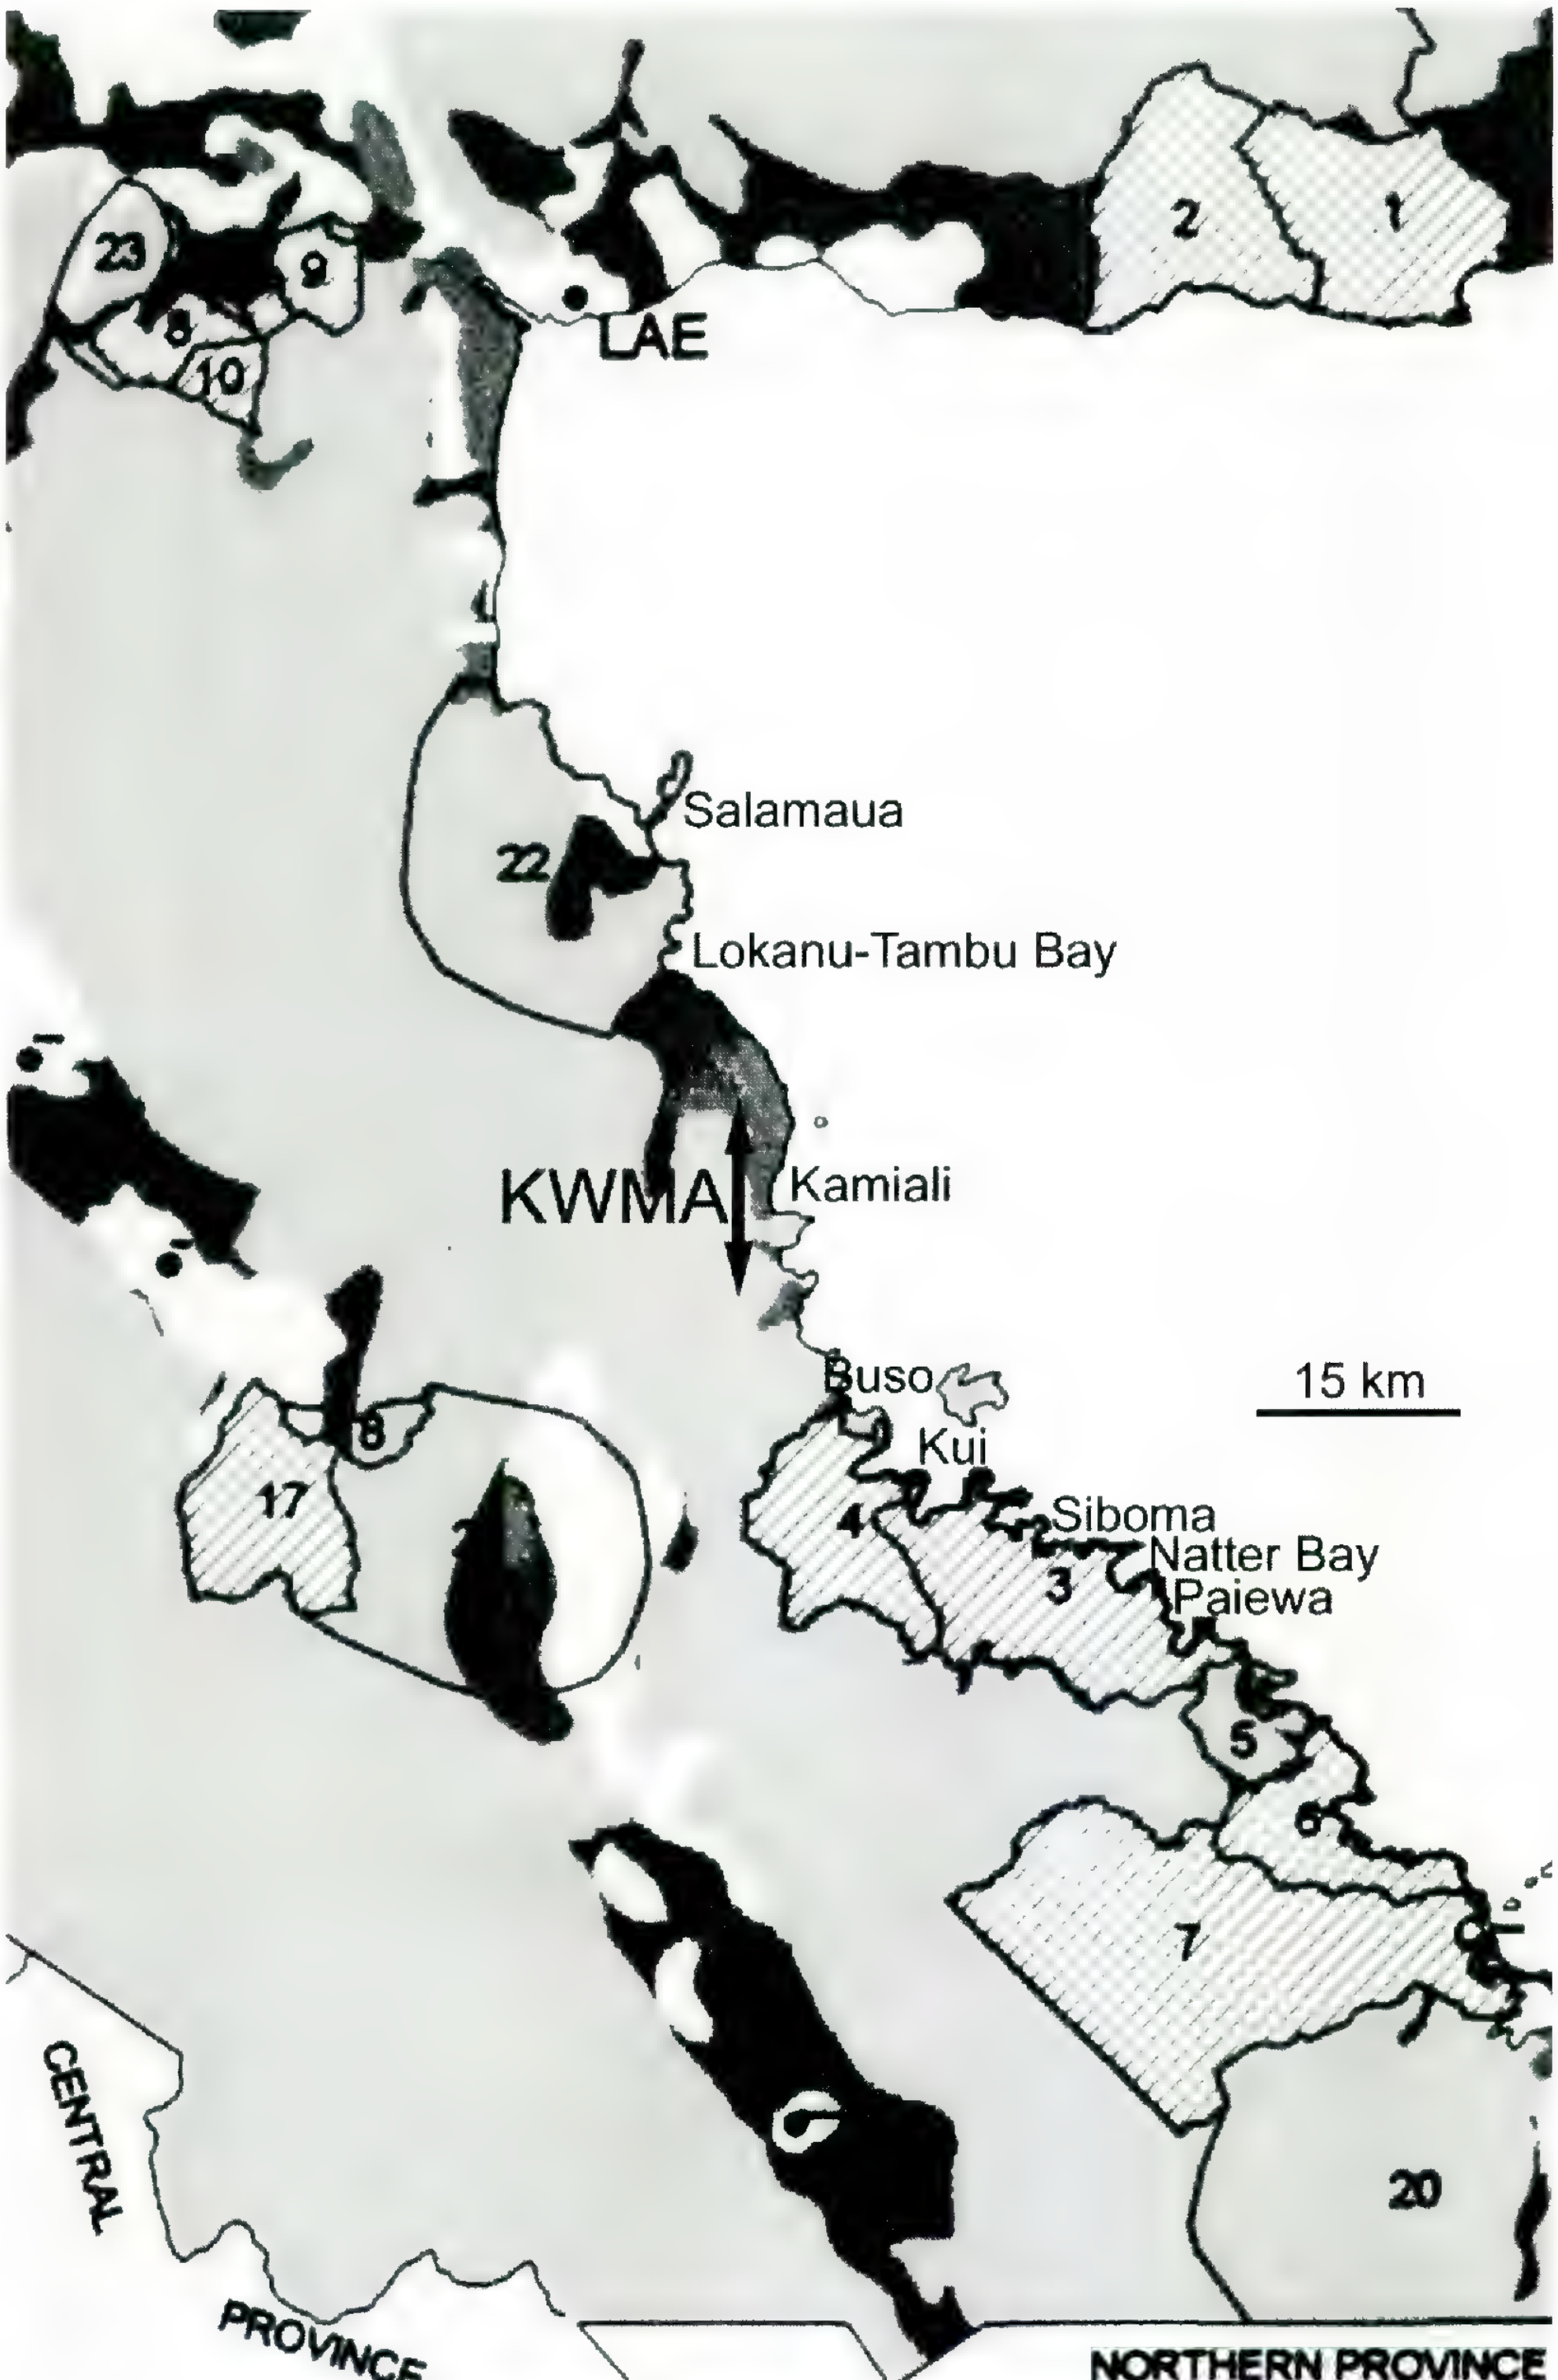

FIG. 5. Forest production areas in south Morobe (striped blocks 3–7). 3. Kui Buso TP (Timber Purchase); 4. Kui Buso extension TP; 5. Maiama-A TP; 6. Maiama-B TP; 7. Morobe TP. mechanisms such as cyclonic storms and El Niño events. In depauperate forests with monodominant canopies (e.g. Hawaii), a complete suite of species and forest successional stages can be encompassed by tracts as small as 100–200 ha (Mueller-Dombois 1980). But New Guinea floristic environments are among the richest in the paleotropics, and the minimum-area requirements are several orders of magnitude higher. Jeffries (1996) for example, gives 50,000 ha as a lower limit for biodiversity protection, while Beehler and Alcorn (1993) go as high as 800,000 ha. Even within that wide interval, the existing Kamiali easement falls substantially under target. Against this background, the impending expansion of the KWMA to a southern boundary near Paiewa will help to address some of the biological requirements implicit in ICAD design. Sanctioned by local communities in 2002, the new development will bring ca. 300,000 ha of terrestrial environment under conservation management (Kisokau & Siga, pers. comm. Feb. 2003).

Although traditional cultures in PNG are often depicted as being based on consultation and consensus, achieving a determination of common purpose or directed action is never easy. Centrifugal forces are powerful in local politics, as clan, subclan, and kinship self-interests are more important than any perception of the common good (Martin 1998). Expansion of ICAD operations from Kamiali into adjacent territories is certain to aggravate the difficulties inherent in management of customary lands. Those same problems previously led to the polarization of the original Lasanga-Lake Trist conservation plan. The successful resolution of conflicts arising from parochial motivations will determine the effectiveness of the enlarged VDT conservation area at Kui-Siboma and of possible future expansion along the coastal corridor to Oro (Northern) Province. Whether this can actually be achieved within the context of the ICAD philosophy is very much an ongoing issue of considerable future significance to conservation in PNG.

The Physical Environment

Climate.—The KWMA lies mostly within Morobe's lowland and premontane climatic zones, where the mean annual rainfall is 3,000–4,000 mm. The wettest months generally occur during January–April, when prevailing winds are northwesterly, and the driest in May–August when the winds are replaced by southeasterly trades (McAlpine et al. 1983). Even during the dry season, mean monthly rainfalls are generally around 200 mm, and the vegetation is rarely subjected to water shortages under normal circumstances (ibid.: 140). Most climatic classifications would describe the project sites as tropical everwet or perhumid, reflecting the overall absence of moisture deficits.

In the western Pacific, El Niño oscillations are typically accompanied by severe droughts in rainforest environments like the Bowutu Range. During the 1997–98 disturbance, coastal tracts adjacent to the KWMA were subjected to

devastating fires which destroyed substantial areas of forest (Fig. 6). Formerly covered with primary growth, Lasanga burned out of control during the 1997–98 drought and is now a weedy island. In marked contrast to the El Niño episodes, the periods of peak rainfall are often accompanied by severe flooding in the lowlands and numerous landslides on higher slopes. In 1999 the La Niña rains resulted in torrential surges along the main rivers emptying into Nasau and Sachsen Bays, completely destroying the subsistence gardens on the Bitoi Delta. As the KWMA rivers overflowed their banks, the flood waters flattened wide channels through the surrounding alluvial forest. The botanical team subsequently enjoyed unprecedented access and easy collecting along the corridors of felled canopy, which years later, are now becoming clogged with impenetrable thickets of *Calamus*.

Geology.—Much of New Guinea's diversity has been shaped by a complex and dynamic geological past. Although the southern part of the island is an extension of the Australian craton, the northern districts are a melange of former island arcs which rafted onto the mainland during the northward migration of the Australian landmass (Dow 1977; Jaques & Robinson 1975; Pigram & Davies 1987). The Papuan Peninsula, consisting of the SE-trending 'tail' of New Guinea, represents the remnants of an accreted arc (Hamilton 1979).

The Bowutu Range forms a major portion of the Papuan Peninsula and is also PNG's most extensive elevational series of ultramafic landscapes (Dow & Davies 1964). This general region is part of a terrane complex paleohistorically distinct from the rest of northern New Guinea, having docked with the mainland ca. 10 m.y. after the Sepik terranes (Pigram & Davies 1987). The area's unusual geology has led to its recognition as a separate physiographic province, extending from the Kamiali coastline to the craggy summits of the Owen Stanley Range (i.e. the Papuan Ultrabasic Belt, cf. Bain 1973; Löffler 1977; Thompson & Fisher 1965). Between Lokanu-Tambu Bay and Kui village, the ultrabasic belt forms a continuous series of lowland environments. The offshore islands such as Lasanga and Musik are part of a different (nonserpentine) geological series reaching southwards to the Waria River (Dow & Davies 1964) and are excluded from consideration in this paper.

Soils.—Ultrabasic environments are characterized by substrates low in silica, but with high magnesium and iron contents. In addition to deleterious magnesium/calcium ratios, ultrabasic soils are frequently associated with phytotoxic concentrations of nickel, chromium, and cobalt (Brooks 1987; Whitmore 1975). The influence of heavy metals is often cited as being responsible for the stunted vegetation of serpentine habitats, though it should be noted that low-statured canopies are not an invariable feature of ultramafic forests (see Fox & Tan 1971; Proctor et al. 1988).

Bowutu populations from at least one species [*Rinorea bengalensis* (Wall.)

FIG. 6. Bulili Ridge. Forest burn from the 1997–98 El Niño drought.

O.K.], are known to accumulate nickel (Brooks 1987). There are no reports of heavy metal accumulation in other native plants. A brief discussion of serpentine floras in New Guinea is provided by Brooks (ibid.), Paijmans (1976), and van Royen (1963), but there is a conspicuous absence of floristic data in such accounts. A summary of ultrabasic vegetation is otherwise available for the tropical far east (Proctor 1992). While it is generally recognized that ultrabasics are associated with depauperate canopies easily discerned in aerial photographs (Paijmans 1976), the species composition of the communities remains poorly known for Papuasia. Comparative studies from Western Malesia show wide variation in the structure and endemism of such floras (Proctor et al. 2000).

Ultrabasic terrain in PNG is characteristically composed of massive ridges with uniform slopes and unstable soils (Löffler 1977; Paijmans 1976). The topographic instability of the study area is reflected in the presence of old landslip scars on many mountainsides (Figs. 7–8). Earthquakes with shallow epicenters are common in northern New Guinea (Hamilton 1979), and can aggravate local tendencies for landsliding. Quake-triggered landslides have been responsible for many fatalities in Morobe Province.

The KWMA hill habitat is unsuitable for agriculture (Bleeker 1975a, 1975b) because of erosion hazards and the general infertility associated with serpen-

FIG. 7. Sachsen Bay. Landslide behind mangrove community.

tine substrates. In contrast, the flood plain of the major streams (Bitoi, Tabali, Arawiri, and Saia),[2] have deep deposits of organic alluvium (Fig. 9). The Bitoi Delta between the Areta (N) and Daunawa (S) branches is a particularly fertile tract in which nearly all the Kamiali food gardens are concentrated. Unlike many Highlands areas where intensified cropping has led to lowered productivities (see Levett & Bala 1995), the KWMA agricultural system has surplus capacity capable of supporting twice the present population (Bein et al. in press, in submission). The high productivities are due to the presence of rich delta soils and their renewal by seasonal floods (ibid.).[3] These factors have enabled the adoption of a shortened 7-year garden cycle (vs. an estimated 20 years in normal slash and burn rotations). At current rates of population increase, the existing subsistence system can probably satisfy local needs for 35 more years without any expansion in area (Wagner 2001b).

The Social Environment

The total population of Kamiali was 520 in August 1997. There are two major

[2] On contemporary maps the Arawiri (Ariwiri) is shown as the Alealer River, and the Saia as the Sela River (Rova Australian Survey Corps Series T601, Nasau sheet 8383, Edition 1 AAS, 1:100,000)

[3] Martin (1998) specifies a Bitoi crop rotation of 3–4 years and suggests the standard rotation period at nearby Kui village is 10–15 years. Levett and Bala (1995) give 7–20 years as the standard swidden cycle for PNG

FIG. 8. As for figure 7, showing the successional community. The seral taxa include mainly *Dicranopteris linearis*, *Machaerina glomerata*, *M. rubiginosa*, *Myrtella beccarii*, and *Stenocarpus moorei*.

Fig. 9. Saia River. Several new fish species have been discovered in the clear-flowing streams of the KWMA.

clans, the Gara and Tabali, and at least 12 subclans (Martin 1998, 1999). Kela is the indigenous tongue, one of approximately 200 comprising the Austronesian language group of northeastern New Guinea (McElhanon 1984; Wurm 1985). Nearly all villagers also speak the lingua franca of PNG (i.e. Tok Pisin). With the recent establishment of a community school, most children have acquired at least some understanding of English.[4]

Seemingly unstructured to western observers, local village life is actually governed by an extensive network of customary practices and expectations. Inheritance and property rights are matrilineal by tradition, but considerable change is occurring as a result of exposure to modern influences. Martin (1998, 1999, 2001) and Wagner (2001b) provide an informative discussion of social developments in their specific connection to conservation.

Despite their retention of customary lifestyles, Kamiali inhabitants are surprisingly sophisticated and informed, a direct result of the quality-of-life improvements introduced by the Village Development Trust within the past 10 years. Several community leaders for example, are computer literate and maintain international email contacts from VDT's offices in Lae. As another sign of

[1]There are 6 principal Kela-speaking villages on the Huon coast, divided into two apparent dialect groups. Kamiali has its closest linguistic and kinship affinities to the hamlets of Buso and Kui immediately to the southeast, the latter centers having been established by migration of Kamiali settlers during a former time of epidemic (Martin 1998)

cultural change, researchers are required to establish a Memorandum of Understanding with village-appointed representatives, disclosing the purpose of an intended study and affirming its obligations to the Kamiali people.

The KWMA villagers are dependent on marine resources for their livelihood (mainly reef fishing) supplemented by a limited range of garden crops. Cash incomes are small and sporadic, on a household basis typically falling between PGK 500–4,000 per year (at current rates 1 PGK=0.25 USD), mostly from the sale of fish, sea shells, and betel nuts (Martin 1998; Wagner 2001b). Although the Kamiali territory consists predominantly of primary forest rich in animal life, only three individuals from the village population (Enok Nasa, Tani Jena, Tom Ziena) are known to actively hunt wild game such as cuscus, pigs, cassowaries, and wildfowl. For a people with copious forest resources, remarkably little use is made of the terrestrial environment. Even among the small hunting fraternity, forest forays are apparently undertaken mainly for recreation, and overnight trips are rarely attempted. To a certain extent, the apparent avoidence of inland habitats may be due to a belief in animalism and spirits (masalai), even though all villagers profess devotion to the Christian (Lutheran) faith. For whatever reason, there is essentially no human presence in the interior areas above 500 m. Since subsistence farming is confined to the flood plain on the Bitoi Delta (a tract of ca. 460 hectares), human impacts on the environment are practically nonexistent (Martin 1998; Wagner 2001b).

The Logistical Environment

In geographic regions with the environmental qualities of New Guinea, investigators have little difficulty identifying biologically suitable localities for botanical research. During the selection of potential study sites, the logistical limitations imposed by poor civil infrastructures often take precedence over the biological concerns. When viewed in this context, the KWMA offers a particularly attractive combination of site attributes.

In addition to exceptional floristic quality, the coastal location of the KWMA and its proximity to Lae (the second largest city in the country) provide researchers with unusually cost-effective logistics. There is no other conservation locality in PNG offering equivalent accessibility and scientific value in one package. While many natural areas are of similar interest, their remoteness and associated travel costs discourage longterm study. Although the KWMA has no roads or airstrips, the site can be conveniently reached by outboard-equipped dinghies ('speedboats').[5]

On the shores of Nasau Bay the Village Development Trust maintains a permanent training center, guest houses, on-site staff, wireless communications, and sea transport. Primary forest is immediately adjacent to the accommodations,

[5]Travel time is 2.5 hours from Lae by 40 hp outboard and 1.5 hours by 70 hp. Charter rates for 40 and 70 hp speedboats are PGK 600 and PGK 800 respectively (roundtrip Lae-Kamiali).

allowing easy access to serpentine vegetation. With electric generators for the facilities available on continuous standby, researchers are able to live and work under conditions conducive to high morale and productivity. Of particular importance to scientists using customary lands, access and intellectual property issues have been successfully negotiated via VDT-brokered agreements with local landowners. In recognition of these infrastructural advantages, the KWMA was selected as the principal PNG site for elevation-sequenced studies in the Pacific-Asia Biodiversity Transect network (PABITRA; Takeuchi 2003a, digital images on http://www.senckenberg.uni-frankfurt.de/odes/).

In conformity with the ICAD concept, ecotourism is actively encouraged as an environment-friendly enterprise within the conservation zone. Kamiali's scenic shoreline of white-sand beaches is currently a featured scientific attraction, with nearly 5 km of waterfront serving as active nesting sites for the endangered leatherback turtle. Substantial numbers of science-oriented visitors arrive during the haul-out season in November-March to observe the turtle tagging operations (Kisokau & Dutton 2002; Lindgren 1999a). In marked contrast to the spartan conditions at most research venues, the KWMA's ambience and infrastructure are comparable to a vacation resort.

Kamiali's checkered history forms a colorful backdrop to these present-day assets. During WWII Nasau Bay was the site of a major battle between Allied and Japanese forces (see Lindgren 1999b, 2000, for a popular account), and many war artefacts, including aircraft and ordnance, are still present in the area (Figs. 10–11). Local guide services are available at modest cost to tourists and other visitors.

The Biotic Environment

Although Paijmans (1976) believed that no native plants are restricted to ultrabasics, there is mounting evidence that such substrates are in fact associated with substantial endemism. In addition to the presence of localized endemics, serpentine environments are also noted for distributional anomalies, particularly by taxa occurring at elevations far below their usual centers. This pattern is especially pronounced on the Bowutu ultrabasics, where the *Massenerhebung* effect of coastal mountains (see Grubb 1971; Grubb & Stevens 1985; Whitmore 1975) combines synergistically with substrate effects. Many low-elevational records can be expected from such situations, since the KWMA is PNG's only conservation locality where serpentine communities are disposed in a continuous sequence from sealevel to cloudy summits.

Nearly all information from Bowutu environments are from easily-studied coastal localities. The montane and inland areas have been neglected despite their presumed biotic significance. In recognition of these deficiencies, the Bowutu Range is included among PNG's 16 terrestrial unknown areas and as one of the five most critical watersheds requiring conservation action (Sekhran

FIG. 10. Unexploded US 500 lb GP bomb from the KWMA. Explosives recovered from WWII-vintage munitions are often used in near-shore fish dynamiting, a practice implicated as a principal cause of reef damage and declining fish stocks. Such bombing is illegal in PNG and is also outlawed under the KWMA's organic rules (Anonymous, Sept. 19, 1996), but the prohibitions are not vigorously enforced. Photo Karol Kisokau.

& Miller 1995). Johns (1993) had listed the district with 42 other localities of greatest floristic importance for PNG. The estimate of 4,000+ plant species for the area is among the highest of any existing conservation site (ibid.).

In 1997 a multidisciplinary survey was concluded within the KWMA, focusing primarily on marine and land-fauna documentation (Bein et al. 1998; Bein 1999). The botanical inventory started in 1998 immediately after the animal surveys had ended. Taken collectively, the biotic assessments have examined coastal and alluvial swamps, lowland rainforest, premontane foothill forest, and mossy cloud forest. The collections density (CD: 890 plant specimens per 100 sq km) is very high by Papuasian standards, but this figure is misleading because much of the collecting has been confined to the lowlands.[6] The montane communities are still poorly known, even though most of the floristic diversity is probably concentrated at the higher elevations. Approximately 20 new plant species have been discovered during the ongoing investigations (Huynh 2001, 2002; Pipoly & Takeuchi in submission; Stevens in submission;

[6]The overall CD for Papuasia is only 30 collections per 100 sq km (Frodin 1990). The atypical nature of the Kamiali sampling coverage is evidenced by the near-absence of collections from above 500 m elevation. In other PNG environments, the montane areas are usually much better known than the lowland habitats.

FIG. 11. Rusting 81 mm mortar shells from the KWMA. In 1943 Nasau Bay was the site of an amphibious assault by the US 32nd Division and a land attack from Wau by the Australian 32 Bde (Burns 1991). Photo Karol Kisokau.

Takeuchi 2001, 2003b). The findings obtained to date provide evidence of a continuing potential for discovery in one of PNG's most distinctive floristic environments.

MATERIALS AND METHODS

In contrast to Rapid Biological Assessments, the botanical survey was based on a plan involving numerous visits to the KWMA. Fieldtrips of 1–2 weeks duration were conducted at ca. 4 month intervals during the 4-year survey. With a schedule of repeated visits, fertile specimens were acquired throughout the year, and even infrequently-flowering taxa could be collected. Because of the KWMA's logistical advantages, studies employing such itineraries can achieve a more complete and cost-effective coverage than efforts based on single visits. The benefits of conducting small-area inventories over extended periods of time have been discussed by earlier commentators (e.g. Prance 1977).

Forest communities were examined by walk-through collecting and visual assessment, operating either from campsites established in the bush, or from the KWMA science facilities at Lababia Ridge and Kulindi (Figs. 12–14). The explorations were generally confined to the lowland zone below 500 m. Plant collections were usually made in sets of 3–5 duplicates, but if a specimen was believed to have special significance, this was increased to ca. 10 duplicates. At

FIG. 12. Parataxonomists collecting along the Saia River.

the Kulindi Science Center, electric generators enabled gatherings to be dried by artificial heat immediately after collecting in adjacent forests. Otherwise when operating from bushcamps, the gatherings were field-pressed in newsprint and plastic bags, then soaked with 70% ethanol for subsequent processing in Lae (Fig. 15). Silica-dried samples for DNA sequencing were also obtained if specialists had placed earlier requests for assistance.

In Appendix 1, the survey specimens have been tabulated together with earlier numbers from the ultrabasics at Buso and Kui.[7] The ultrabasic boundary extends southeast from Kui village, passing immediately inland from Braunshweig Harbor at Siboma (Simpoma). Specimens from Kui are appended with a (K) on the checklist, to indicate when the material is from the ultrabasic boundary and may have been obtained from non-serpentine terrain. Natter Bay and Paiewa represent Tertiary substrates of different age and origin from the Bowutu ultrabasics (Dow & Davies 1964), and are thus omitted from the compilations.

The Paiewa drainage is intersected by an extensive network of logging tracks along which a few collections were made under the NGF series (e.g. *Gillison NGF 22489–22500, 25011–25049*). Some of the upstream areas at Paiewa are inside the ultrabasic belt, but the locality data are too ambiguous to determine the substrate status of such collections. Jacobs's numbers from 'opposite

[7]Author citations for binomials are provided in the text for names which are not in the appendix.

FIG. 13. Bulili Ridge. Survey team in ultrabasic forest.

FIG. 14. The Kamiali Science Center facilities at Kulindi, on the beachfront of Nasau Bay. Natural-growth ultrabasic forest is immediately adjacent to the compound. A substantial number of undescribed taxa have been discovered in the general area.

Lasanga Island', are similarly difficult to interpret with respect to their substrate association.

Much of the methodology and rationale for the Kamiali surveys have been discussed elsewhere (Takeuchi 2003a). As with many recent efforts, the itinerary was implemented by village teams involving institutional parataxonomists D. Ama, Nathan, and/or A. Towati, or as a larger workforce supervised by colleague B. Siga and the writer.

GENERAL DESCRIPTION OF THE VEGETATION

The physiognomy of the KWMA lowland flora is similar to a montane forest, with a preponderance of small-leaved species and a general absence of vining, cauliflorous, or compound-leaved plants (Fig. 16). Plank-buttressed trees are rare. To some extent, these characteristics are due to the anomalous presence of higher-elevation species in lowland habitats. Many sealevel distributional records were documented by the recent surveys (e.g. see discussion on *Astronidium morobiense*).

The KWMA regrowth phase (between sealevel to at least ca. 500 m elev.) is dominated by *Commersonia bartramia*, *Decaspermum bracteatum*, *Dicranopteris*

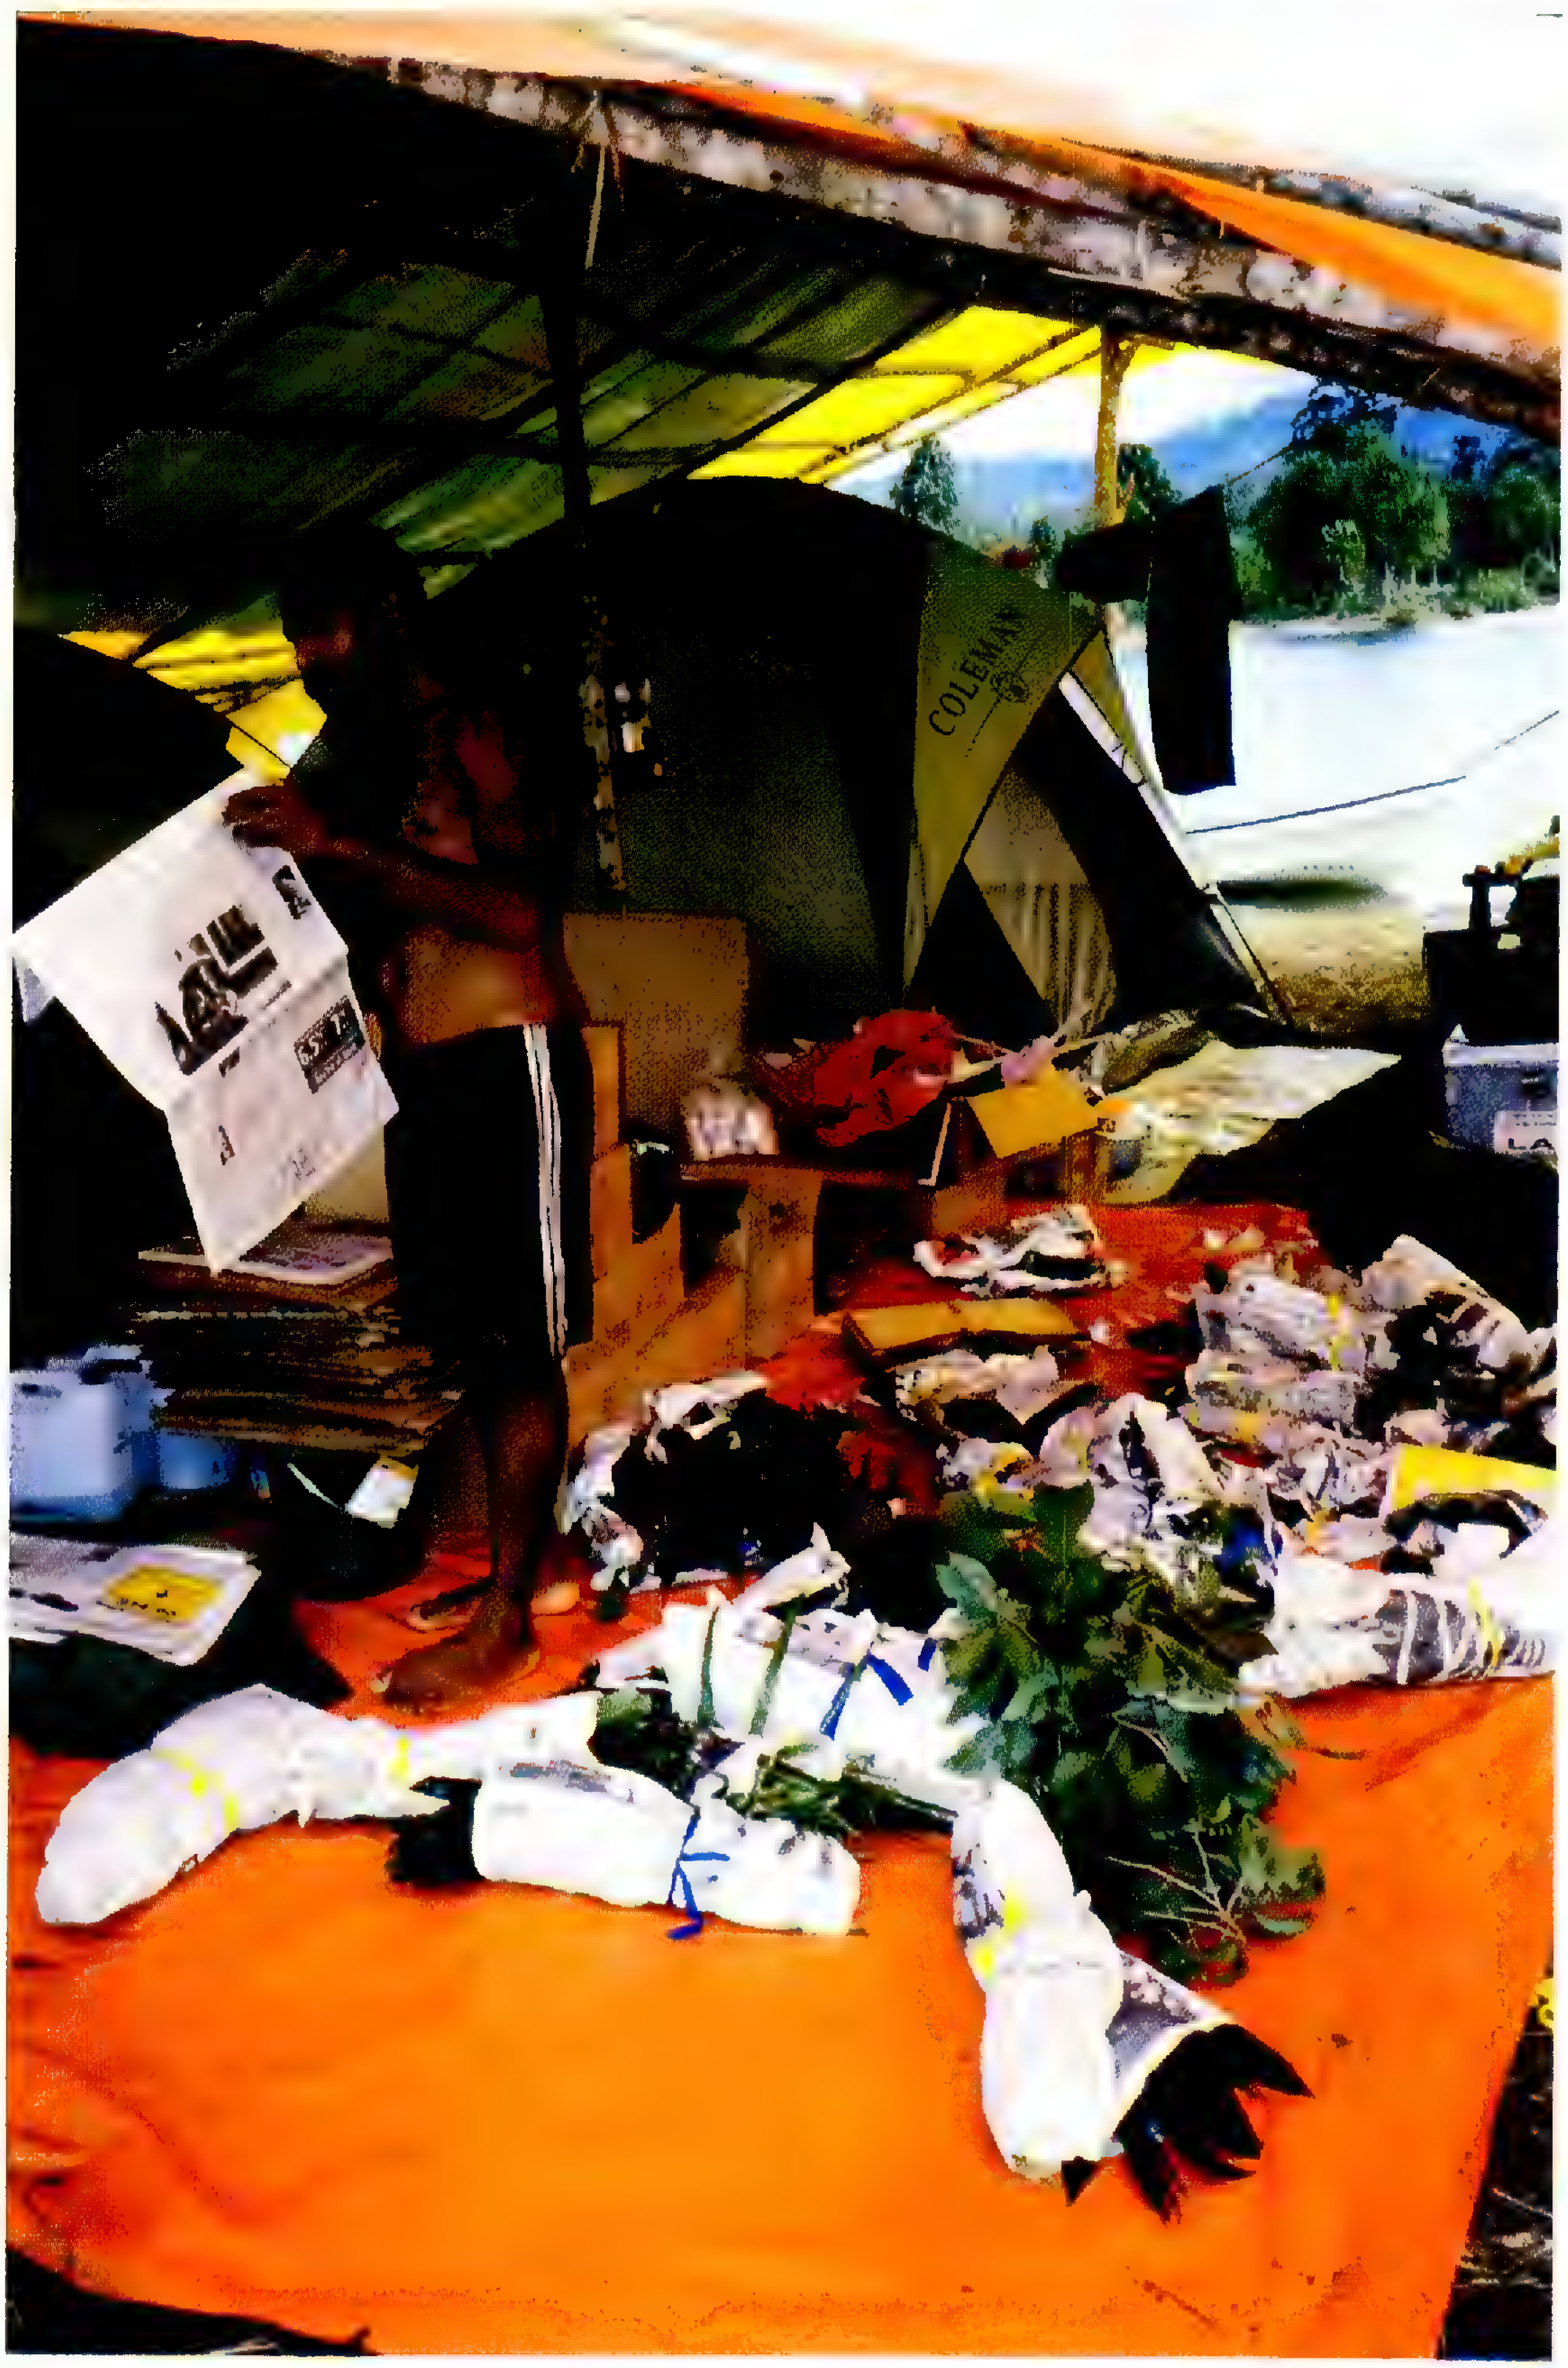

FIG. 15. Processing of plant specimens in the field. Gatherings are individually wrapped in newsprint to protect the collections during the trek back to basecamp, where they are then packed in ethanol.

FIG. 16. The Bulili ultrabasic forest extends to the highwater line on Nasau Bay.

linearis, *Myrtella beccarii*, *Schuurmansia henningsii*, and *Timonius paiawensis*. Many of the seral or pioneer taxa normally found in Mamose environments are absent or uncommon.[8] *Cyathea*, *Cypholophus*, *Dendrocnide*, *Endospermum*, *Glochidion*, *Gouania*, *Leea*, *Macaranga* (except for *M. bifoveata*), *Mallotus*, *Musa*, *Mussaenda*, *Omalanthus*, *Pipturus*, and *Trichospermum* are conspicuously missing or are insignificant in the floristic succession on ultrabasics (Fig. 17). Even the aggressive weed *Piper aduncum* rarely manages to establish in seemingly opportune situations. Similar patterns have been noted in the Raja Ampat serpentine district of Irian Jaya (Takeuchi 2003b).

Within the lowland ultrabasic flora as a whole, a number of ordinarily speciose families are clearly under-represented. The impoverished groups include Araceae, Begoniaceae, Combretaceae, Dilleniaceae, Gesneriaceae, Malvaceae (sens. str.), Marantaceae, Moraceae, Urticaceae, Verbenaceae, and Vitaceae. The representation by ferns and their allies is also poor in comparison to regular substrates at comparable levels of rainfall.

[8]Mamose is the administrative region in northern PNG consisting of *Ma*dang, *Mo*robe, and the *Se*pik provinces. The name is an acronym formed by the first two letters of the provinces, and is also rendered as 'Momase', by the same procedure. Although 'Mamose' is universally understood within PNG, its use is virtually unknown outside the country. There is a certain utility in its usage, because the word refers by coincidence to a part of PNG defined by tectonic and biotic similarities, and thus represents a discrete evolutionary environment.

FIG. 17. Fire succession in the former burn area shown in figure 6. After 4 years, the regrowth consists mainly of *Macaranga bifoveata* (shrubs in photo) and *Machaerina glomerata*. Other colonizers are *Trema cannabina* and *Commersonia bartramia*.

In addition to the impoverished groups, floristic depauperation is further evidenced by the absence of several families which should be present in lowland environments of northern PNG. The families which were not seen included Commelinaceae (notably *Amischotolype* and *Pollia*), Cycadaceae, Dichapetalaceae, Hernandiaceae, Opiliaceae, Ruscaceae (*Dracaena angustifolia* Roxb.), and Tetramelaceae (*Octomeles sumatrana* Miq.). In contrast, Euphorbiaceae, Myrtaceae, and Rubiaceae (except for *Ophiorrhiza* and *Mussaenda*) are exceptionally common. Other families represented by large numbers of individuals are Burseraceae, Clusiaceae, Cyperaceae, Meliaceae, Myristicaceae, Myrsinaceae, and Pandanaceae. However there is an obvious general reduction in floristic diversity, as evidenced by the low species counts relative to other New Guinea environments. The PABITRA transect investigations are currently providing quantitative data for defining these patterns (Sengo in prep.).

One direct consequence of low alpha diversity in KWMA habitats is the disproportionate presence of a small group of plants. Certain taxa are nearly everywhere in the lowland ultrabasic forest. Among understory shrubs and subshrubs, these 'weedy' elements include *Casearia* aff. *erythrocarpa* (sp. ?nov.), *Conandrium polyanthum*, *Fittingia tubiflora*, *Geniostoma rupestre*, *Ixora* sp. (sp. A on checklist), and *Syzygium trivene* sens. str. The understory fern *Lindsaea obtusa* is the most ubiquitous pteridophyte. *Anisoptera thurifera* ssp. *polyandra*, *Hopea glabrifolia*, *Myristica chrysophylla*, *Syzygium furfuraceum*, and *Tristaniopsis macrosperma* are similarly abundant in tall-growth canopy. *Gymnostoma papuana* (exposed ridges and riverbanks) and *Stenocarpus moorei* (streambanks and landslips) often form locally monodominant stands in repetitively disturbed habitats. The subcanopy and middle layers in hill forest below 500 m are dominated particularly by *Brackenridgea forbesii*, *Canarium* spp., *Garcinia* spp., *Gordonia papuana*, *Gymnacranthera farquhariana* var. *zippeliana*, *Haplolobus floribundus*, *Polyosma* cf. *forbesii*, and *Syzygium effusum* sens. lat.

The KWMA lowland vegetation is thus characterized by a limited number of very common species. The disharmonic nature of the flora is similar to insular environments from more isolated stations within the Pacific, and the prevailing patterns are reversed to some extent only in the coastal and alluvial flats bordering the major waterways. In such locations, some of the missing taxonomic elements reappear, presumably due to a reduction in soil toxicity. Alluvial substrates in the KWMA have acidity values to pH 4, unlike the ultrabasic substrates on ridges (Bein, pers. comm. March 2000). There are thus two general floristic associations within the lowland KWMA: 1) a macrophyllous, liane-rich community characteristic of riverine/swampy environments, and 2) a highly disharmonic ultrabasic flora of contrasting generic composition and with some of the attributes of a montane vegetation.

Although *Alyxia acuminata* sens. lat., *Freycinetia* spp., *Hugonia jenkinsii*,

and *Psychotria olivacea* are moderately common in ultrabasic forest, climbing taxa are generally notable by their absence or rarity. Apocynaceae (Asclepiadoideae), *Calamus*, Convolvulaceae (with the exception of *Erycibe*), *Dichapetalum*, *Flagellaria*, *Gouania*, Lomariopsidaceae, *Mucuna*, *Stenochlaena*, *Tecomanthe*, *Uncaria*, and all Vitaceae, are often absent or rare even from open streamcourses and other edge environments where such taxa are ordinarily prevalent. Understories are also remarkably clear, and physical passage through the forest is decidedly easier than with most lowland communities.

On the current forest mapping system for PNG (Hammermaster & Saunders 1995a, b) the Bowutu ultrabasic vegetation is primarily classified as a small-crowned lowland hill forest (code Hs, ibid.), reflecting the overall stunting of the serpentine canopies. KWMA ultrabasic stands are easily detected in aerial photos because of their depauperate appearance, changing only at the transition to regular substrates, where the canopy develops larger, medium-sized crowns (code Hm, e.g. at the Kui ecotone).

In contrast to ultrabasic communities, the alluvial habitats are primarily seral environments, often *Gymnostoma*-dominant and subject to seasonal flooding. These riverine successional areas are generally restricted to the coastal floodplains where the KWMA's clear-flowing streams emerge onto the lowlands (see Hammermaster & Saunders 1995b: Salamaua SB 55-15 overlay). In other low-lying sections near the coast, like the beachfront opposite Lababia Island, the presence of poorly drained flatland is associated with *Metroxylon*-monodominant swamps (Wsw; ibid.). The coastline vegetation also includes scattered seagrass shallows (*Enhalus acoroides*), *Bruguiera-Rhizophora* mangroves, and tidal estuarine forest (Fig. 18), but the areas encompassed by such communities are below the resolution of existing vegetation maps.

DESCRIPTIONS OF NEW SPECIES

RUBIACEAE

Psychotria bulilimontis Takeuchi, sp. nov. (**Figs. 19–21**). TYPE: PAPUA NEW GUINEA. MOROBE PROVINCE: Kamiali Wildlife Management Area, lower slopes of Bulili Mt, multistoried ultrabasic forest, 07° 18.5' S, 147° 07.5' E, 20 m, 6 Oct 2002 (fl, fr), *W. Takeuchi & D. Ama 16428* (HOLOTYPE: LAE!; ISOTYPES: A, BISH, BO, BRIT, CANB, K, L, MO, NSW, US).

Species haec ab aliis congeneribus papuanen inflorescentiis lateralibus fructibus globosisque rhachidi inflorescentiarum teretibus statim distinguitur.

Understory shrub 3–4 m in height, erect, often polelike, sparingly or moderately branched, outer bark thin, dark gray, smooth. **Branchlets** terete, slightly compressed at the top, subapical diam. 2–3(–4) mm, spreading, weak, surfaces green in the leaf-bearing intervals, furfuraceous at the stipular scars, otherwise glabrous, internodes (1–)2–6 cm long. **Leaves** diverging in one plane, glabrous; blades fleshy or subcoriaceous, without domatia or cystoliths, adaxially dark

FIG. 18. *Bruguiera-Rhizophora* mangrove forest at Hessen Bay, KWMA.

FIG. 19. *Psychotria bulilimontis* var. *bulilimontis* in the ultrabasic forest on Bulili Ridge. White arrow: stem base of the type individual.

FIG. 20. *Psychotria bulilimontis* var. *bulilimontis*. The type gathering (*W. Takeuchi & D. Ama 16428*).

FIG. 21. *Psychotria bulilimontis* var. *bulilimontis*. Closer view of the fruit and cymules (*W. Takeuchi & D. Ama 16428*).

green, abaxially mid-green, bifacially olivaceous after drying, linear-elliptic, (7–)12–21 by (1.5–)3.5–6.5 cm, apex gradually acuminate, margins entire, base cuneate, equal; venation pinnate, secondaries 7–12 pairs, (7–)10–22 mm apart, at the lamina center diverging 55–70° from the midrib, arcuate, brochidodromous, tertiary nervation areolate, all venation plane or weakly raised on upper surfaces, prominulous beneath; petiole 8–20 by 1.0–2.0 mm, adaxially channelled or flattened, rounded beneath; stipules valvate, linear-acuminate, to 15 by 4 mm, brownish-green, caducous, adaxially furfuraceous at the base, otherwise glabrous, apex bifid, the arms 3–4 mm long, filiform. **Inflorescence** axillary from the subapical and lower nodes, glabrous, lax, paniculiform, ultimately cymose, the primary branches opposed or 3-verticillate, all axes spreading, light green, delicate (0.5–1.0 mm wide); peduncle (10–)50–85 mm long, primary branches to 25 mm long; peduncular bracts caducous; rachis bracts persisting at the branching points, acuminate, 1–3 mm long; floral bracts triangular, minute. **Flowers** (measurements from spirit-preserved material) tetramerous, glabrous on exterior surfaces, 5.0 mm long, sessile; calyx infundibular, 2.7 by 1.8 mm, limb dentate, teeth ca. 0.2 mm long, erect at anthesis; corolla sympetalous, valvate, white, tube 2 mm long, pilose in a 1 mm wide band at the mouth, lobes ovate, 2.0–2.5 by 1.8 mm, apex acute; stamens alternipetalous, erect, glabrous, anthers exserted, oblongoid, ca. 0.8 mm long, basifixed, introrse, filaments very short, attached at the sinus; gynoecium glabrous, ovary globular, recessed at the summit, style included, ca. 0.6–0.7 mm long, stigma lobes ca. 0.5 mm long, coherent. ***Fruits*** shiny orange-red when ripe, juicy, subglobose, 5 mm diam. *in vivo*, crowned by the calycine residue; pyrenes 2, pale yellow-brown, 2–3-ridged on the back, inside farinaceous, no ruminations.

Distribution and ecology.—*Psychotria bulilimontis* is known only from lowland environments within the Kamiali Wildlife Management Area. The nominate variety is restricted to the ultrabasics.

Etymology.—The epithet commemorates the type locality.

PARATYPE: **PAPUA NEW GUINEA. Morobe Province:** Kamiali Wildlife Management Area, lower slopes of Bulili Mt, multistoried ultrabasic forest, 07° 18.5' S, 147° 07.5' E, 20 m, 25 Aug 2002 (fl, fr), *W. Takeuchi, D. Ama, B. Siga, & Nathan 16416* (A, L, LAE!).

Axilliflorous *Psychotria* are rare in New Guinea. Only *P. axilliflora* Merr. & Perry and *P. dipteropoda* Laut. & K. Sch. are known to flower from subapical nodes. The new species is easily distinguished from its axilliflorous congeners by the globose fruits (fusiform and compressed in *P. axilliflora*) and by the delicate, terete axes of the inflorescence (conspicuously flattened and broad in *P. dipteropoda*).

Psychotria bulilimontis var. **aestuarii** Takeuchi, var. nov. (**Figs. 22–23**). TYPE: PAPUA NEW GUINEA. MOROBE PROVINCE: Kamiali Wildlife Management Area, banks of the Saia River near Hessen Bay, alluvial-estuarine forest, 07° 21.6' S, 147° 07.3' E,

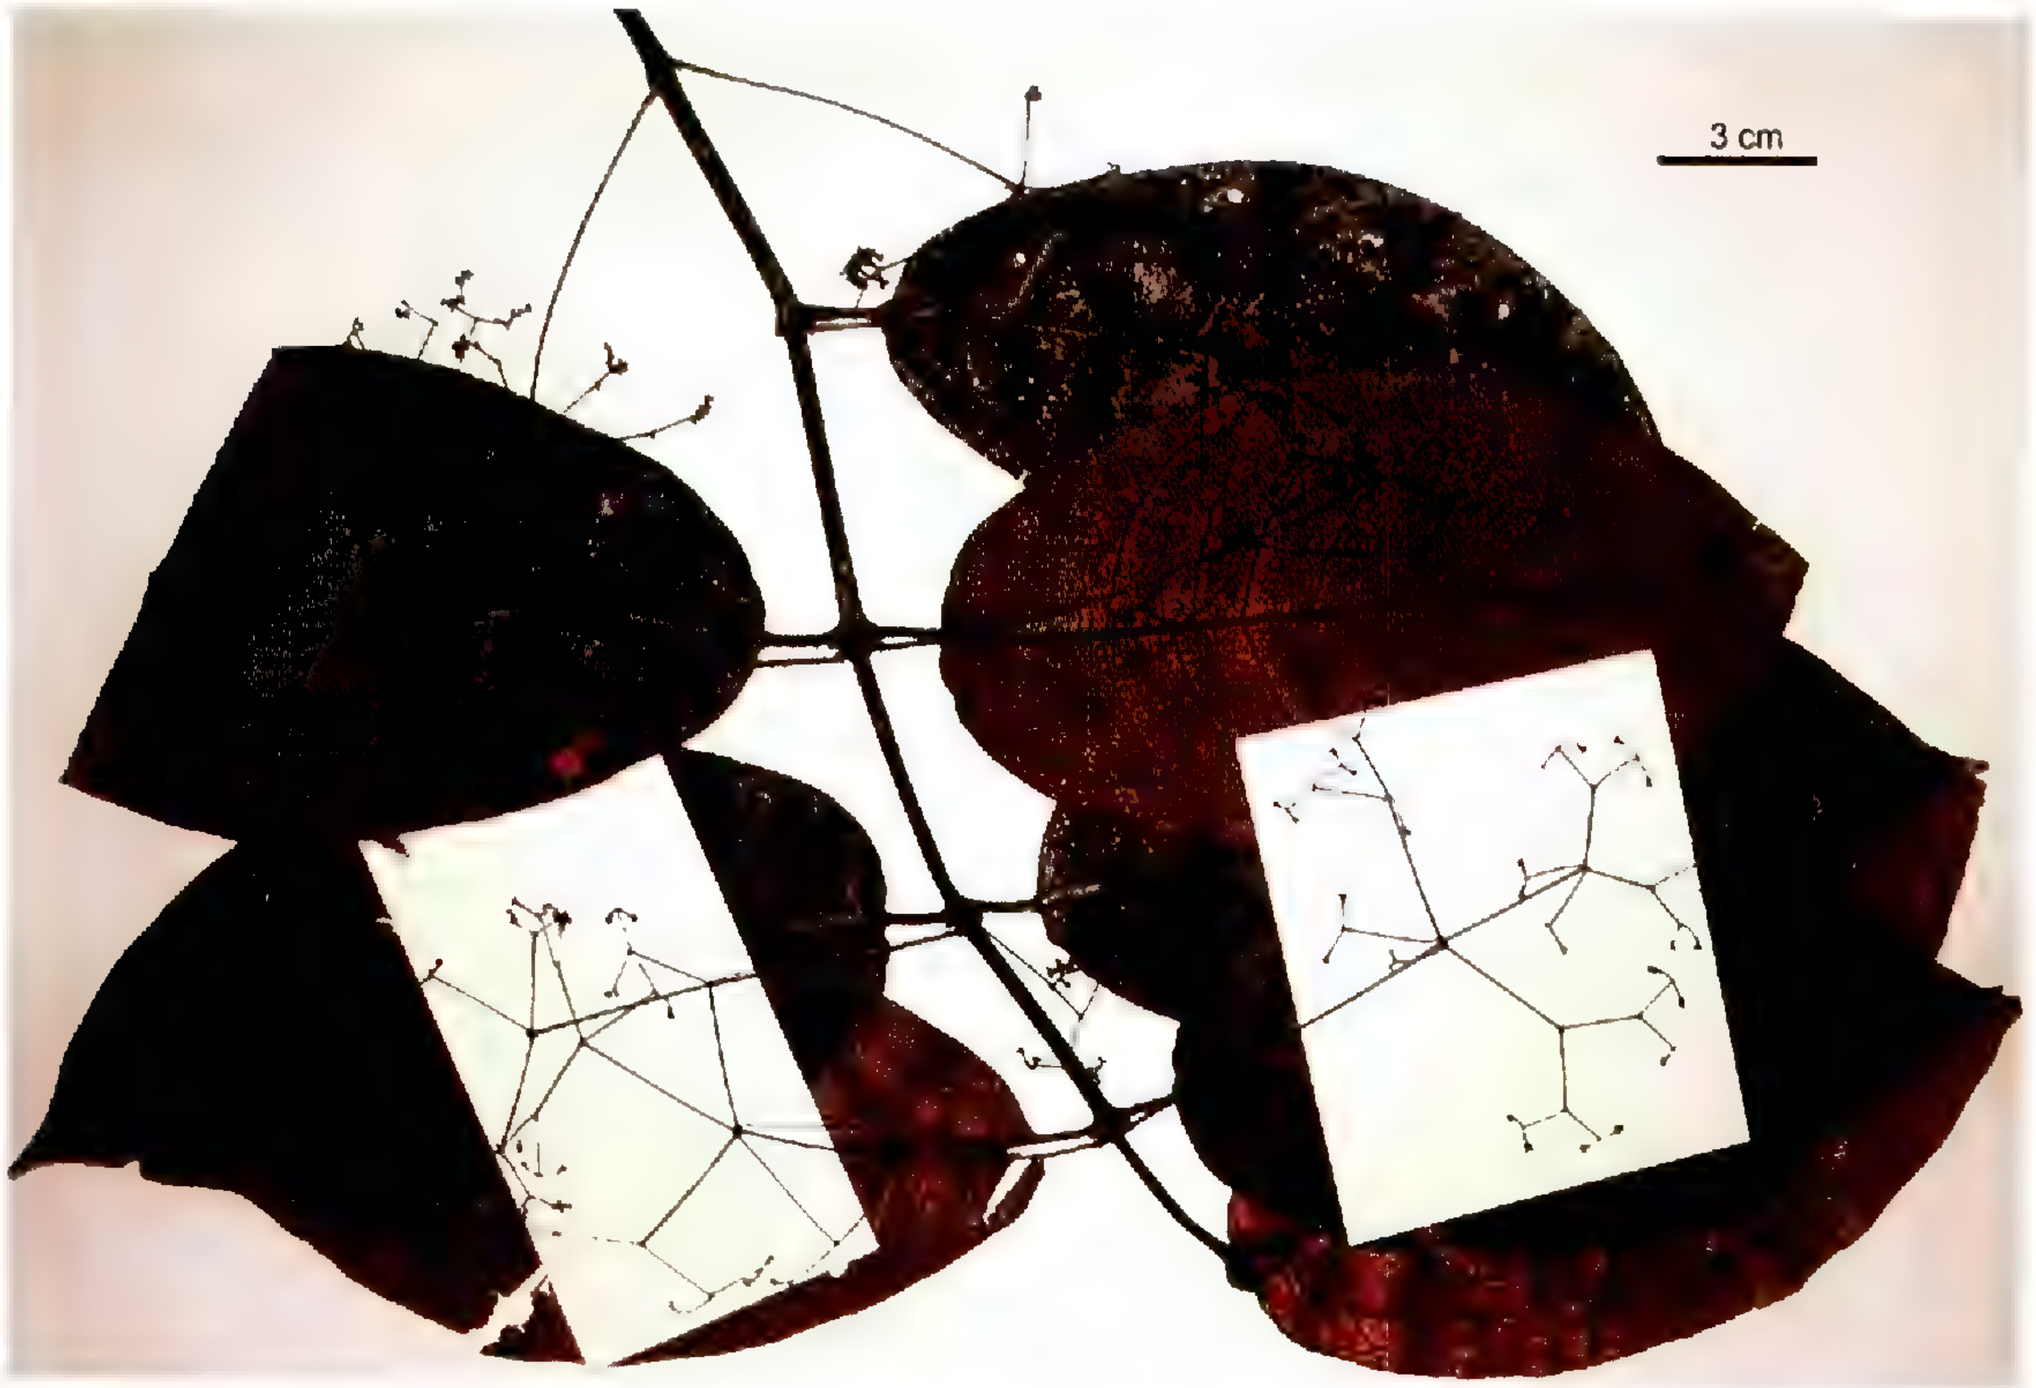

FIG. 22. *Psychotria bulilimontis* var. *aestuarii*. An unmounted duplicate from the type gathering. The delicate, umbelliform inflorescence is characteristic (*W. Takeuchi, B. Siga, & A. Towati 14993*).

FIG. 23. Hessen Bay. Estuarine forest habitat of the type population for *Psychotria bulilimontis* var. *aestuari*.

5–10 m, 15 Jan 2001 (fl), *W. Takeuchi, B. Siga, & A. Towati 14993* (HOLOTYPE: LAE!; ISOTYPES: A, BISH, BO, CANB, K, L, MO, US).

Ab var. *bulilimonti* laminis latioribus ad bases rotundatis vel cordatis, indumento denso denique inflorescentiis umbelliformibus praeclare distinguitur.

Understory shrub 1–2(–4) m in height, erect, sparingly or moderately branched. **Branchlets** obliquely ascending, weakly compressed near the summit, terete below, subapical diam. 2–4 mm, hirtellous, hairs persisting, internodes (2–)4–7(–11) cm long. **Leaves** distichous, spreading; lamina usually fleshy, adaxially dark dull green, abaxially pale green or brownish-green, discolorous after drying, turning black or fuscous above and rufous-brown beneath, upper surfaces glabrous, marked by linear cystoliths or not, lower surfaces hirtellous, hairs orange- or reddish-brown, densest on midribs and veins, domatia absent; blades variable, narrowly to broadly elliptic, ovate, or obovate, (9–)13–23 by (3–)6–11 cm, apex acuminate, margins entire, base subcordate, rounded, (or cuneate); venation pinnate, secondaries 10–12 pairs, (7–)15–20(–28) mm apart, at the lamina center diverging (35–)50–70° from the midrib, arcuate, more or less brochidodromous but reticulating freely beyond the commissural loops, tertiary nervation conspicuously and coarsely areolate, all venation plane or impressed on upper surfaces, prominulous beneath; petiole 5–20 by 1.5–2.0 mm, adaxially channelled or flattened, rounded beneath, indument like the branchlets; stipules valvate, caducous, lanceolate-ovate, to 15 by 5 mm, apex bifurcately divided into 3–4 mm long filiform caudae, exterior surfaces coarsely hairy, inside furfuraceous-barbate along the base, otherwise glabrous. **Inflorescence** axillary from the subapical and lower nodes, umbelliform or paniculiform, the ramifications verticillately branched for 1–3 orders, ultimately cymose, all axes spreading, lax, hirtellous, delicate (0.5–1 mm wide), dull light green; peduncle (10–)35–95 mm long, primary rays to 31 mm long, secondary rays to 16 mm long; peduncular bracts caducous, linear-acuminate, to 3.0 by 0.5 mm; rachis bracts subpersisting at the branching points, acuminate, ca. 1 mm long; bracteoles triangular, ca. 0.5 mm. **Flowers** (measurements from spirit-preserved material) tetramerous, 5.0 mm long, sessile; calyx tubular, 2.0 by 1.5 mm, puberulent, limb dentate, teeth reflexed at anthesis; corolla sympetalous, valvate, white, outer surfaces glabrous, tube 1–2 mm long, mouth pilose, lobes oblong, 2.6–2.7 by 1.2–1.3 mm, apex obtuse or acute; stamens alternipetalous, erect, glabrous, anthers oblongoid, ca. 0.5 mm long, basifixed, introrse, filaments very short, attached at the sinus; gynoecium glabrous, ovary recessed at the summit, style exserted, ca. 4.5 mm long, stigma conspicuously bilobed. **Fruits** immature, globose.

Distribution and ecology.—Known only from coastal forests in the Kamiali Wildlife Management Area.

Etymology.—The varietal name reflects the estuarine forest habitat of the type population.

PARATYPES: **PAPUA NEW GUINEA. Morobe Province:** Kamiali Wildlife Management Area, banks of the Saia River near Hessen Bay, alluvial-estuarine forest, 07° 21.6' S 147° 07.3' E, 5–10 m, 15 Jan 2001 (fl), *W. Takeuchi, B. Siga, & A. Towati 14990* (A, L, LAE!); ditto, *W. Takeuchi, B. Siga, & A. Towati 14995* (A, BO, K, L, LAE!, MO); ditto, *W. Takeuchi, B. Siga, & A. Towati 15002* (A, BISH, BO, CANB, K, L, LAE!, MO, US).

Variety *aestuarii* is clearly referable to *Psychotria bulilimontis*. The lax and delicate inflorescence from lowermost axils is very distinctive and characteristic of the species. However unlike the nominate variety, the alluvial plants are very hairy shrubs with broad leaves and a pronounced tendency for umbelliform branching on the inflorescence. In contrast, the ultrabasic populations (var. *bulilimontis*) are essentially glabrous, with narrow leaves gradually tapered at both ends, and a more paniculiform inflorescence. Both varieties have heterostylous flowers.

SALICACEAE

Trichadenia sasae Takeuchi, sp. nov. (**Figs. 24–27**). TYPE: PAPUA NEW GUINEA. MOROBE PROVINCE: Kamiali Wildlife Management Area, base of Bulili Ridge at Kulindi, ultrabasic forest, 07° 18' S, 147° 08' E, 0–5 m, 4 Feb 2003 (fr), *W. Takeuchi, D. Ama & B. Siga 16561* (HOLOTYPE: LAE!; ISOTYPES: A, BO, CANB, K, L).

Species haec ab aliis congeneribus laminis cordatis usque ad 31.5 cm longisque 27.0 cm latis, dense velutinis fructibus magnis 4 cm diametris perfacile recognoscitur.

Canopy tree 25 m tall, unbuttressed, highly branched, outer bark gray, thick, rough-textured, slash orange-brown, without exudate, sapwood pale yellow. **Branchlets** terete, 12–15 mm in diam. below the leaf spray; indument subpersisting, orange-brown velutinous, usually with a monolayer of erect septate hairs, sometimes also with an underlayer of crispate hairs; periderm dark gray, longitudinally fissured; abscission scars conspicuous, patelliform, 4–10 by 7–12 mm. **Leaves** spirally congested in apical tufts, spreading; blades coriaceous, bichromatic *in vivo*, adaxially dark green, abaxially yellowish-green, olivaceous *in sicco*, the mature laminae manifestly cordate, 22.5–31.5 by 20.5–27.0 cm, apex obtuse, (emarginate, or mucronate), margins entire or irregularly repand, depth of basal sinus (2.0–)2.5–4.0(–5.5) cm; upper surfaces pilosulous on veins, glabrescent between, lower surfaces velutinous; venation plinerval-palmatiform at the petiole, pinnate above the base, craspedromous, secondaries 5–8, (15–)30–70(–85) mm apart, at the lamina center diverging (45–)50–55(–60)° from the midrib, straight (or arcuate), sometimes sparingly anastomosing before the margin, tertiary nerves scalariform, reticulum conspicuously and bifacially areolate, adaxially impressed, all venation prominent below; petioles strictly cylindrical, 5–10 cm by 2.5–4.0 mm on apical leaves, progressively longer on lower leaves (to 18 cm by 5.0 mm), swollen at both ends, geniculate, indument like the branchlets; stipules caducous, subulate, 7–12 mm long, densely hairy. **Flowers** unknown. **Infructescence** solitary from axils of attached leaves, densely velutinous; peduncle ca. 10 mm long, rachis terete, 10–20 by 3–7 mm, unbranched;

FIG. 24. *Trichadenia sasae*. Crown form of the type individual (*W. Takeuchi, D. Ama & B. Siga 16561*).

bracts linear-acuminate, 1.5–2.0 mm long, caducous; pedicels 1.5–3.0 by 5–6 mm, articulated at the rachis. **Fruits** indehiscent, pendulous, globose, 40–43 by 38–43 mm, bilobed or obscurely trigonous, (38–47 by 46–55 mm), epicarp pale grayish-brown through all stages of maturation, lenticellate, laxly hirtellous (glabrous to naked eye), surface scrape bright green, no exudate, pericarp thin (ca. 1 mm), crustaceous, entire *in vivo*, usually collapsing and coarsely rugose after drying; mesocarp at first straw-pale brown, later yellow and baccate, ripe pulp fleshy, no odor; seeds 1–3, endosperm copious, white, turning pink after sectioning.

Distribution and ecology.—*Trichadenia sasae* is known with certainty only from the closed-canopy forest bordering Nasau Bay. All confirmed sightings have occurred on the ultrabasics.

Etymology.—The new species is named after colleague Sasa Zibe-Kokino, a professional forester and prominent conservation advocate, currently serving as the Member of Parliament for Huon electorate.

PARATYPE: **PAPUA NEW GUINEA. Morobe Province:** Kamiali Wildlife Management Area, base of Bulili Ridge at Kulindi Science Center, ultrabasic forest, 07° 18' S, 147° 08' E, 0–5 m, 25 Nov 2001 (fr), *W. Takeuchi, D. Ama & B. Siga 15589* (A, BO, CANB, L, LAE!, MO, US).

The genus *Trichadenia* was previously represented in the Malesian region only by the widely distributed *T. philippinensis* Merr. A second species (*T. zeylanica*

FIG. 25. As for figure 24, looking into the crown from below.

FIG. 26. *Trichadenia sasae*. Detached branchlets from the type gathering.

FIG. 27. *Trichadenia sasae*. Parataxonomist Demas Ama holds a fruiting branchlet against the bole.

Thwait.) is endemic to Ceylon (Sleumer 1954). The new *Trichadenia* is easily recognized by its large cordate leaves, dense indument, and large fruits.

The field appearance of *T. sasae* is similar to the *Sterculia ampla-macrophylla* complex and is thus almost impossible to identify from a distance. The type tree was for several years misidentified as a *Sterculia* due to the gross similarities in habit. There are apparently several individuals of this species along the Bulili coast but few have been seen in fertile condition. The species is not common within the KWMA.

NOTES ON OTHER TAXA

CONVOLVULACEAE

Erycibe spp.—*Erycibe* is generally an uncommon genus in PNG. When last treated by Hoogland (1953a, b) and Oostroom (1953, 1955), most taxa were known from only a small number of specimens. The current species concepts are ill-defined, in part due to the former scarcity of materials for study and by what appears to have been an excessive splitting of the variation. As is generally true of canopy lianes with brightly colored fruits and inconspicuous flowers, most of the modern gatherings consist of fruiting material which are less useful than flowering ones. The genus is greatly in need of revision.

In contrast to most PNG localities, *Erycibe* is well represented within KWMA alluvial habitats, but all existing specimens are in fruit and cannot be keyed out. While many Morobe collections are apparently conspecific with the KWMA species, none of the sheets has been reliably identified and the assigned names seem to have been taken up by successive collectors in uncritical fashion. The KWMA *Erycibe* are neither rare or new, but the difficulties involved in their identification are symptomatic of a greater problem with the genus as a whole.

CYPERACEAE

Cladium mariscus (L.) Pohl sens. lat.—A cosmopolitan species, but rare in New Guinea and not previously recorded for PNG (Hay 1984). LAE has no recent accessions from New Guinea other than the survey voucher.

FABACEAE

Maniltoa sp. (Verdcourt sp. E)—The only *Maniltoa* recorded in the ultrabasic lowlands is apparently an undescribed taxon closely related to *Maniltoa schefferi* K. Sch. & Hollrung. On Verdcourt's (1979) alphabet list of novelties, the KWMA plants are referable to species E, distinguished by sessile ovaries and fruits. *Maniltoa* E is very common within the hill forest and consistently maintains its separate character. There are no transitional forms to *M. schefferi*. The KWMA *Maniltoa* is apparently restricted to the serpentine zone and is arguably best regarded as a subspecies. In other characters, species E is so similar to *M. schefferi* that it would be inappropriate to establish a new species on just one differentiating trait.

LECYTHIDACEAE

Barringtonia spp.—At least five species of *Barringtonia* have been documented on the ultrabasics (*B. apiculata*, *B. asiatica*, *B. lumina*, *B. pinifolia*, and *B. racemosa*; see Jebb 1991). KWMA *Barringtonia* are partitioned by habitat into two groups, with *B. asiatica* and *B. racemosa* occurring mainly along the coast, and the remaining species ranging into the upper drainages and interior hill forest. *Barringtonia pinifolia* is particularly common within alluvial communities near the base of the main range. In comparison, the distinctive *B. lumina* was seen only a few times along the Saia River and is apparently rare.

Barringtonia is widely employed as a fish poison in lowland New Guinea (ibid.; Payens 1967; Peekel 1984) but Kamiali villagers apparently use only *Derris trifoliata* ('rop dynamit') for fishing. This situation is certainly not due to a lack of availability, since *Barringtonia* spp. are present in large, easily-accessed populations around the main village and fishing camps. Some respondents claim that *Derris* is more effective on the reefs than *Barringtonia*, but this assessment is not universal. Although the use of plant poisons for fishing is a well-established practice in Kamiali society, it has been traditionally discouraged except in special circumstances (Martin 1998, 1999). The growing frequency of reef bombing and *Derris* 'dynamiting', are manifestations of the changes occurring within Kela society, and of the declining influence of customary observances.

MALVACEAE

Sterculia sp. nov., aff. **ampla-macrophylla** group

Sterculia sp. ?nov., aff. **shillinglawii** F.v.M.

The KWMA has two possible novelties in *Sterculia*.

Tantra (1976: 75–6) regarded *Jacobs 9639* from the Buso-Kui foothills as a new species in the *ampla-macrophylla-morobeensis* group, but formal description was deferred pending acquisition of more complete material. No new collections have been made since the initial gathering in 1973. A series of numbers from the current survey also cannot be identified with Tantra's conspectus (ibid.), and may represent another undescribed species.

MELASTOMATACEAE

Astronidium morobiense Maxw. (**Figs. 28–29**).—The species was previously known only from mossy fagaceous forest between 1350–1800 m near Wagau (Maxwell & Veldkamp 1990). However recent determinations (ex S.S. Renner, pers. comm. March 2003) indicate that the species is distributed southwards along the Morobe coast as far as Natter Bay, with occurrences in both ultrabasic and non-serpentine habitats.

In marked contrast to the environment specified in its protologue, the KWMA populations of *A. morobiense* are found primarily at low elevations. On Bulili Ridge, the species is even found at sealevel, immediately behind the highwater line and in forest occasionally subject to saltwater damage. Between

FIG. 28. *Astronidium morobiense*, in the sealevel ultrabasic forest near Kulindi, KWMA.

FIG. 29. As for figure 28, showing the inflorescence (*W. Takeuchi & D. Ama 16223*).

Lokanu-Tambu Bay and Kui village (Fig. 5), the only remaining hill forest is on the headlands bordering Sachsen and Hessen Bays (e.g. Cape Dinga and Cape Roon). The communities in or near these areas often have taxa at their lowest elevations of record (e.g. *Astronidium morobiense*, *Bhesa archboldiana*, *Gnetum costatum*, *Hunga papuana*, *Lophopetalum torricellense*, *Mackinlaya schlechteri*, *Nastus schlechteri*, *Ormosia calavensis*, *Paphia*, *Psychotria archboldii*, and *Syzygium richardsonianum*).

MYRSINACEAE

Fittingia urceolata Mez and **F. tubiflora** Mez (**Figs. 30–31**).—These obviously related species are sympatric and vegetatively indistinguishable. *Fittingia urceolata* is noticeably more frequent on the ultrabasic substrates than its congener, but the two often occur side by side outside the serpentine (e.g. the foothills at Paiewa). The only distinction between the species is in the color of the drupes (red for *F. tubiflora* and white for *F. urceolata*; Sleumer 1988).

Sleumer (ibid.) suggested the apparent difference in fruit color might not be an adequate basis for discrimination between the species, although he accepted the separation in his revision. Field observations from the recent surveys show that the color contrasts are indeed consistent and effective discriminators. In *F. tubiflora* the red color is evident even in the ovary of the anthetic flower (label data for *14429*) and is preserved as the fruit develops through a marble-like phase and eventually into the spongy-textured drupe from which the generic name is derived. Whether or not a species pair should be upheld on the basis of a single contrasting character is a matter of subjective judgment, but the color distinction is certainly not some transient feature related to fruit maturation—i.e. white fruits do not ripen into red fruits or vice versa. It may be more appropriate to relegate the taxa to varietal rank, but in any event, there is a readily detectable difference in living material.[9]

MYRTACEAE

Syzygium trivene (Ridley) Merr. & Perry and **S. lorentzianum** Laut.—*Syzygium lorentzianum* was known to Hartley and Perry (1973) only from the type. The species is supposedly distinguished from *S. trivene* by slight differences in leaf form and by the longer flower buds (ibid.: 177).

Within the KWMA, *S. trivene* sens. str. is one of the most common subarborescent taxa of riverine understories and interior forest. From examination of the survey's many numbers, it is evident that the characters separating this species from *S. lorentzianum* are part of an intergrading series of variation. In general, *S. lorentzianum* is the name of a robust form growing in exposed areas (e.g. along streambanks) while *S. trivene* is the spare variant of closed

[9]Most of the survey duplicates were distributed indicating a synonymy between the names (i.e. as *F. tubiflora* = *F. urceolata*.

FIG. 30. *Fittingia urceolata*. The pericarp is hyaline green in the immature fruit, but turns opaquely white with ripening (*W. Takeuchi, A. Towati, B. Siga, & M. Kavua 16172*).

FIG. 31. *Fittingia tubiflora*. In contrast to the congener, fruits are red from the start of their development (there is no green phase). The initially hard pericarp becomes spongy-textured and somewhat juicy when ripe (*W. Takeuchi, B. Siga, & A. Towati 14991*).

forest. The distinctions appear environmentally determined and thus undeserving of formal recognition. *Syzygium trivene* should be regarded as a synonym of *S. lorentzianum*, since the latter has the older epithet.

POACEAE

Nastus schlechteri (Pilger) Holtt., or aff.—The condensed panicles and aristate basal glumes are distinctive. Apparently known only from the type (*Schlechter 19720*), which was not seen by Holttum (1967) and presumably lost at Berlin.

The KWMA collections are from atypically low elevations for the genus, having been obtained from ca. 100 m, but the vouchers otherwise conform to Holttum's species description and the key (ibid.).

RUBIACEAE

Psychotria archboldii Sohmer, **P. mayana** Takeuchi, **P. melanocarpa** Merr. & Perry—Indument and fruit color are the principal means for separating these taxa. *Psychotria archboldii* is entirely glabrous on all parts, while *P. mayana* and *P. melanocarpa* have stelliform hairs. Although *P. archboldii* has red fruits, the drupes are white in *P. mayana* and black in *P. melanocarpa*. The three species are apparently geographically separated. Only *P. archboldii* var. *archboldii* has an appreciable distribution, occurring from Morobe to Milne Bay and offshore islands (var. *multinervia* is known by a single collection from Gulf Province), while *P. mayana* and *P. melanocarpa* have been found only in Madang and Western Provinces, respectively. Apart from these distinctions, the plants are obviously related and can be plausibly regarded either as sibling species, or as geographically separate subspecies. Herbarium specimens from the *archboldii-mayana-melanocarpa* complex are visually striking, with bright orange-brown or rufous leaves. The large fruits are invariably jet black on exsiccatae, irrespective of the coloration *in vivo*.

In *P. archboldii* as a whole, there is considerable doubt about the fruit color, a character widely employed by Sohmer (1988) as a basis for species separations among the Papuasian congeners. Although variety *archboldii* is recorded as having red fruits, the KWMA populations of this variety were collected with white drupes. The fruits of *P. archboldii* var. *multinervia* are also supposedly white, according to the label for the only existing specimen (though the variety was formally described as having red fruits).

The discrepancies could be explained if *P. archboldii* has distinct color phases with the fruit maturing from white to red, or less plausibly from red to white. However such color changes have never been substantiated for any Papuasian *Psychotria*. If fruit color has no significance in this species complex, the present separations should be dismantled and recognition given only to geographic subspecies or races.

Psychotria croftiana Sohmer—*Psychotria croftiana* is a large-leaved species pre-

viously known from three fruiting collections on the Huon coast (Sohmer 1988). It is a common and conspicuous shrub in the ultrabasic forest but also occurs on the nonserpentine substrates southeast of Buso. The distinctively papillate-hairy flowers were unknown until the recent surveys. A supplementary description of the flowering plant can be provided from the new material:

Inflorescence paniculate, pyramidal, exceeding the leaves at anthesis, to 37 by 29 cm, all axes glabrous; peduncle 7–13 cm long, first order branches 3–4-verticillate, to 17 cm long; rachis bracts acuminate, 2–6 mm long, abruptly subulate at the apex, subpersisting, abaxially glabrous, adaxially furfuraceous at the base; floral bracts inconspicuous, linear or linear-acuminate, ca. 0.5 mm long; pedicels 1–2 mm long; cymes lax. **Flowers** (measurements from rehydrated material) 5(–6)-merous, 2.5 by 3.5 mm at anthesis; calyx infundibular (shallowly cupular when dry), parted about halfway to the base, lobes triangular, equal, ca. 0.5 mm long; corolla white, obovoid in bud, tube 1.7 by 1.8 mm, glabrous on all exterior surfaces, mouth not clearly barbate, lobes adaxially papillate-hairy, acute, 1.0 by 1.2 mm, reflexed at maturity; stamens alternipetalous, anthers erect, oblongoid, 0.6–0.7 mm long, filaments short, inserted about halfway down the tube; gynoecium glabrous, ovary dome-shaped, recessed at the top, style 0.7 mm long, stigma 0.3 mm long, slightly expanded, columnar, 5–6-sulcate, not or only weakly exserted.

Specimens examined: **PAPUA NEW GUINEA. Morobe Province:** Kamiali Wildlife Management Area, lower slopes of Bulili Mt, ultrabasic forest, 07° 18.5' S, 147° 07.5' E, 40 m, 6 Oct 2002 (fl), *W. Takeuchi & D. Ama 16430B* (A, BO, CANB, K, L, LAE!, MO, US); base of Lababia Ridge, ultrabasic forest, 07° 16' S, 147° 06' E, 75 m, Oct 2002 (fl), *W. Takeuchi & D. Ama 16578* (A, LAE!).

Psychotria waiuensis Sohmer—*Psychotria kamialii* Takeuchi, Edinburgh J. Bot. 58:159–161. 2001. TYPE: PAPUA NEW GUINEA. MOROBE PROVINCE: Kamiali Wildlife Management Area, 1.5 km W of Lababia Village, 07° 17' S, 147° 06' E, 5–10 m, 14 Nov 1999, *W. Takeuchi & J. Sengo 14310* (HOLOTYPE: LAE; ISOTYPE: K).

Current fieldwork indicates that the recently described *Psychotria kamialii* must unfortunately be regarded as a synonym of *P. waiuensis*. As the most obvious point of distinction from its closest congeners, the monocaulous habit of *P. kamialii* was the principal character used to establish that species. Because of an emphasis on architectural form, the equivalence to *P. waiuensis* was overlooked. There are several points which can be made in relation to the synonymy.

First, it is very unlikely that *P. waiuensis* is a 10 feet (3 m) tall shrub as indicated in the diagnosis. *Psychotria waiuensis* is not rare, and every plant seen during the recent surveys were monocaulous dwarfs occurring as helophytes in shallow mud or standing water. In this respect the plant is similar to the higher elevation forms of *P. ramadecumbens* Sohmer. The type gathering for *P. kamialii* for example, was a colony sample from sago swamp, taken from separate 0.5 m individuals. The KWMA populations have never been seen growing on firm ground as medium-sized branching shrubs. Although *P. waiuensis* is described

as 'about 3 m' (Sohmer 1988) this figure is probably a label error. It is more plausible that the first collections at Waiu Bay (Braunschweig Harbor on most maps) were also monocaulous subshrubs, as suggested by the fact that the earlier sheets show no indication of branching. Most of the bayfront at Waiu is a coastal swamp similar to the type locality for *P. kamialii*, so a general stunting of woody plants would also be expected at the earlier collection site. Because the actual habit of this swamp species was not appreciated, Sohmer's (1988) key will go astray at fork 107, where there is a couplet separation between monocaulous and branching shrubs. *Psychotria waiuensis* will actually key out to *P. inconspicua* Merr. & Perry, as happened during the initial evaluation of *P. kamialii*.

As presently known, *P. waiuensis* occurs only between Kamiali and Waiu, an area consisting mainly of ultrabasics. However future collectors will probably find this species further south along the coastline, since the swampy forests which the plant inhabits are not restricted to serpentine. Judging from its current habitats, *P. waiuensis* may be present in the coastal wetlands near the Morobe-Waria Rivers, where extensive areas of comparable environment can be found.

Coastal swamps are such disagreeable places that it is easy to understand why only one collection existed of *P. waiuensis* prior to the recent surveys, even though the species is moderately common. The presence of saltwater crocodiles (*Crocodilus porosus*) and swarms of mosquitos are disincentives to loitering in these shoreline areas. The most promising strategy for collectors is to work the ecotone along the margins of the swamps, rather than their interior parts. If the putative differences between *P. waiuensis* and *P. kamialii* are derived from substrate conditions, different growth forms should be found at the contact between swamp and dry land.

SALICACEAE

Homalium d'entrecasteauxense Craven—Formerly known only by the type collection from Normanby Island (Craven 1979). In the survey vouchers, stamens are consistently arranged in 3-membered fascicles. Branchlets are puberulent.

Steenis (1982) expressed doubt over the number of new species recognized by Craven (1979), and of their distinction from the variable *H. foetidum* (Roxb.) Benth. The taxonomic issues are still unresolved because of the limited number of specimens available for study (7 out of the 10 Papuasian species are known only from the types). Multiple collections showing the variation within individual populations are much needed.

The new gatherings from the KWMA suggest that staminal number is an effective criterion for splitting *H. d'entrecasteauxense* from the *foetidum* complex. This separation is corroborated in the field by differences in stature and habit. The Kamiali specimens of *H. d'entrecasteauxense* were taken from frail,

4 m tall understory shrubs, but *H. foetidum* is ordinarily a robust timber-sized tree. The survey specimens also confirm the differences in indument between *H. d'entrecasteauxense* and *H. maneauense* Craven (see modified key in Steenis 1982: 564).

THELYPTERIDACEAE

Plesioneuron croftii Holtt.—Formerly known in the literature only by the type collection from Natter Bay, but now also represented by newer material from the Waria basin and Buso.

Plesioneuron croftii is similar to *P. dryas* Holtt., differing primarily in the color of the aerophores (dark in *P. dryas* and pale in *P. croftii*; see Holttum 1981). The recent collections are closest to *P. croftii* but have dark aerophores, and seem to combine characteristics of that species and its congener. Although the position of the sori near costules is of some value in the identification of *P. croftii* (ibid: 399), the distinction is small and inconstant, and probably unworthy of specific rank.

DISCUSSION

Whether or not floristic patterns discerned in the KWMA are of general application to other floras is unknown, especially as the ultrabasic patterns are difficult to separate from those applying to the Papuan Peninsula as a whole. Although the distribution of ultrabasic substrates can be extracted from the geological literature, information on the associated vegetation is sparse and unsubstantiated. There are no checklists or forest descriptions of representative formations anywhere in PNG. The patterns found at Kamiali may be unique to the Bowutu communities, but at least within the KWMA, the lowland serpentine has been sampled to very high intensities, and is presently one of the better known lowland floras in New Guinea. Approximately 1,915 specimens have been compiled from a lowland area of 215 sq km, for a collections density (CD) of 890 collections per 100 sq. km.[10] The current checklist includes 130 families, 412 genera, and ca. 710 morphospecies. Most of the lowland taxa from the Kamiali area have probably been recorded. In view of the general depauperation of serpentine floras, the species counts primarily reflect the sampling saturation achieved by the surveys, rather than any special richness of the serpentine plant life. At Josephstaal for example, an inventory of lowland rainforest below 400 m recorded a total of 139 families, 445 genera, and 730 morphospecies (Takeuchi 2000), an outcome very similar to the Bowutu study. However the

[10]Stevens (1989) notes that the current benchmark of 50–100 collections per 100 sq km does not necessarily represent a well-collected locality. The Bowutu inventory demonstrates that even at much higher sampling intensities, unknown taxa will escape detection. Once an adequate baseline has been established for a specific flora, further progress will be dependent on how additional collections are distributed through space and time, rather than the mere acquisition of more material.

Josephstaal assessment involved only one month of survey work, while the ultrabasic itinerary was much more intensive, consisting of repeated fieldtrips over a period of four years.

The results at Kamiali have been constrained by the surveys' strict and deliberate focus on the lowland zone below 500 m. On Mt Kinabalu, the speciose character of the vegetation has been attributed primarily to the presence of ultrabasic outcrops in the montane elevations (Beaman & Beaman 1990). Species counts in the KWMA are likely to increase considerably when investigations are extended into the higher habitats where most of the diversity in New Guinea environments are probably concentrated. A substantial number of Bowutu taxa have already been typified from NGF collections made at Lake Trist (elev. 1800 m), mainly by Henty in 1966 (*NGF 29004–29138*). Many of these montane serpentine records are still known only from the original collection, a situation similar to the Kinabalu ultrabasics (ibid.). Existing evidence suggests that a fair number of species remain undiscovered. Unlike Mt Kinabalu however, the KWMA lowland ultrabasics have relatively few species, which for the most part are already well-represented in collections from Buso, Kamiali, and Kui. The recent high-intensity surveys have started to reveal the presence of rarer endemics such as *Discocalyx kaoyae*, *Paphia megaphylla*, and *Trichadenia sasae*. *Mammea papyracea* (*NGF 39414*), *Pouteria gillisonii* Vink (*NGF 25627*), and *P. pullenii* Vink (*NGF 25625*), known only from their types, are also probably rare plants from the ultrabasics (cf. Stevens 1995; Vink 2002).

Despite the extensive work done by earlier botanists at Buso and Kui, the lowland ultrabasics are still a fruitful venue for new material. Even supposedly well-collected localities can be a source of floristic discovery when exploration routes are slightly altered from the previously-used tracks (Stevens 1989). The recent discoveries are a case in point. Papuasian collectors often retrace the field itineraries of previous investigators due to the convenience of following well-used trails. Yet because plant distributions are typically very patchy across seemingly homogeneous or comparable habitats (Oatham & Beehler 1998), slight changes in exploration schedules can be immensely productive. In the KWMA, adjacent ridges often have very different compositions and species frequencies even across the same geological substrates (Sengo in prep.).

Some idea of the conspicuous contrasts in plant distributions and frequencies can be seen when comparing the collections from Buso and Kamiali. For example, *Kairothamnus phyllanthoides* and *Plesioneuron croftii* are common at the former locality, but have not yet been recorded from immediately adjacent Kamiali habitats. Conversely, although *Psychotria bulilimontis* and *Timonius* sp. ?nov. are plentiful in the KWMA hill forest, they have yet to be collected at Buso. Distributional peculiarities are further exemplified by plants that are essentially restricted to the ultrabasics, having high frequencies inside

the KWMA, but which are also known from one or two collections on normal substrates elsewhere on the Papuan Peninsula (e.g. *Astronidium morobeense*, *Guioa grandifoliola*, *Hunga papuana*, and *Zanthoxylum novoguineense*).

Patchiness of the plant distributions on ultrabasics occurs over a range of spatial scales. At one end, are the localized differences reported by Oatham and Beehler (1998) at Lakekamu. These may be due to the dynamic fragmentation of the forest caused by disturbances such as storms and changes in streamcourse. On a larger scale, plant distributions can vary markedly along different ridges or rivers, even though there are no obvious habitat factors separating the occurrences (Frodin 1990; Grubb & Stevens 1985; Kalkman & Vink 1970). The different levels of patchiness have obvious implications for floristic exploration. Perfunctory surveys will probably miss many of the most significant plants, particularly those with quirky distributions. These difficulties are compounded by unpredictable phenologies and the resulting element of chance in the results achieved by surveyors.

Within the Bowutu tract, taxa endemic to the ultrabasic belt include *Calophyllum streimannii*,[11] *Discocalyx kaoyae*, *Freycinetia curvata*, *F. kamialiensis*, *F. mediana*, *F. rubripedata*, *Kairothamnus phyllanthoides*, *Myristica filipes*, *Paphia megaphylla*, *Psychotria bulilimontis* var. *bulilimontis*, and *Solanum symonianum*. The percentage of strict endemics in the local flora is small compared to more extreme environments (e.g. the Waigeo ultrabasics in Irian Jaya, where rainfalls are much lower than in the KWMA; cf. Takeuchi 2003b). Humid conditions appear to reduce the intensity of effects from serpentine substrates. An inverse relationship between rainfall and the severity of the serpentine syndrome has been noted for other areas (e.g. Kruckeberg 1985).

An overwhelming majority of the KWMA species occur on both sides of a serpentine contact, although there are apparent differences in relative frequencies when passing across such boundaries. The floristic contrasts are primarily ones of degree rather than quality. With so many lowland areas being altered by anthropogenic development, the natural distributions of many native species will become difficult to determine in the future. This will complicate comparative studies on PNG's ultrabasic ecosystems . Most of the coastal habitats south of Kamiali are now fragmented by logging damage, and the real range of plants comprising the Papuan Peninsular flora is increasingly obscured by forest destruction.

In view of the general connection between serpentine effects and rainfall, the growing incidence of El Niño-associated droughts is likely to result in future floristic change which will amplify existing patterns. As rainfalls are reduced, ultrabasic effects should increase, and floristic distinctions across the substrate contact at Kui will become more acute. This is likely to be accompanied by a

[11]But *C. streimannii* may be present in Western Province (see Stevens 1995)

sharper physiognomic discontinuity at the contact (i.e. a more obvious reduction in tree statures and crown densities across the boundary). Floristic attenuation can be expected to involve mainly the generalist species that lack serpentine-coping mechanisms. Since many of these plants (e.g. *Canarium*) are used by Kamiali villagers, a reduction in forest ethnobotanical values is probable. Future changes in beta-diversity patterns can also be anticipated in the montane parts of the ultrabasic belt. The KWMA's mossy forests above 500 m were severely affected by the recent El Niño episodes of 1997–98 and 2002. Repeated droughts could result in a lifting of the ecotone and an associated degradation of watershed services.

APPENDIX 1. LOWLAND PLANTS RECORDED FROM KAMIALI

Voucher source for occurrence record: LAE = collections from the Lae Herbarium institutional (new) series; NGF = collections from the New Guinea Force series; nv = non visus, specimen not found at LAE but cited in the literature and/or entered in LAE logbooks; sn = sin numéro (without number); SR = sight record; numbers without prefix = W. Takeuchi et al. (usually with D. Ama, B. Siga, and/or A. Towati). Other collectors indicated by name.

The checklist is a compilation of collections (below ca. 500 m) from the ultrabasic zone between Kamiali and Kui. Specimens from the present survey have been determined by WT unless otherwise noted. Determinations to earlier collections are based on annotations from published revisions or from specialist tickets on herbarium sheets.

FERNS AND FERN ALLIES

ADIANTACEAE

Acrostichum speciosum Willd.; 14896
Adiantum hollandiae v.A.v.R.; 15228
Pityrogramma calomelanos (L.) Link; 15062
Syngramma borneensis (Hook.) J. Smith; 14468
Syngramma grandis (Copel.) C. Chr.; LAE 52303 (nv); NGF 45222
Taenitis blechnoides (Willd.) Sw.; 14642, 14659; Kog 30; NGF 44261; Palis 27

ASPLENIACEAE

Asplenium laserpitiifolium Lam.; 14722, 14840, 14915, 14917
Asplenium cf. *musifolium* Mett.; 14705
Asplenium nidus L. var. *nidus*; 14702; Unkau 96

Acriopsis liliifolia (J. Konig) Ormerod; Vogel et al. 20030827
Agrostophyllum spp.; 14601; Vogel et al. 20030853
Apostasia wallichii R.Br.; 14415, 14748, 15202; LAE 51677; Vogel et al. 20030793, 20030832
Appendicula reflexa Bl.; Vogel et al. 20030791
Appendicula spp.; 15229; Vogel et al. 20030789, 20030790
Ascoglossum calopterum (Rchb. f.) Schltr.; 16443
Bromheadia finlaysoniana (Lindl.) Miq.; 16568; Vogel et al. 20030831
Bulbophyllum blumei (Lindl.) J.J. Sm.; 15201
Bulbophyllum gracillimum (Rolfe) Rolfe; Vogel et al. 20030823, 20030837, 20030838
Bulbophyllum cf. *macranthum* Lindl.; 14594
Bulbophyllum sessile (Koen.) J.J. Sm.; Vogel et al. 20030818
Bulbophyllum sp., sect. *Aphanobulbum*; 15389
Bulbophyllum sp., sect. *Sestochilus*; Vogel et al. 20030807, 20030814, 20030817
Bulbophyllum spp.; 15392; LAE 52323; NGF 31624; Vogel et al. 20030808, 20030809, 20030810, 20030811, 20030812, 20030813, 20030815, 20030816, 20030817, 20030829, 20030836, 20030855
Cadetia funiformis (Bl.) Schltr.; NGF 45195 (det. Schuiteman); Vogel et al. 20030800
Cadetia sp./?spp.; 15213; NGF 45121 (no flowers)
Ceratostylis sp.; 14641
Claderia cf. *papuana* Schltr.; Vogel et al. 20030788
Claderia sp.; Vogel et al. 20030856
Cleisostoma spp.; Vogel et al. 20030850, 20030851
Coelogyne asperata Lindl.; 15154, 15219
Coelogyne cf. *fragrans* Schltr.; Vogel et al. 20030796
Dendrobium austrocaledonicum Schltr.; 15071
Dendrobium bracteosum Reichb.; SR, Saia River
Dendrobium coeloglossum Schltr.; Vogel et al. 20030804
Dendrobium hosei Ridl.; 15227; LAE 52310 (600 m elev.)
Dendrobium lawesii F.v.M.; LAE 52307, 52308, 52309 (600 m elev.)
Dendrobium ?lineale Rolfe; SR, Saia River
Dendrobium macrophyllum A.Rich; 14597, 14599; Vogel et al. 20030843, 20030845, 20030846
Dendrobium spectabile (Bl.) Miq.; 14603; LAE 52330: NGF 45191; Vogel et al. 20030822, 20030842
Dendrobium viridiflorum F.M. Bailey; Vogel et al. 20030840
Dendrobium sp., sect. *Amblyanthus*; NGF 45162 (nv)
Dendrobium sp., sect. *Brevisaccata*; Vogel et al. 20030805, 20030857
Dendrobium sp., sect. *Ceratobium*; 15075
Dendrobium sp., sect. *?Distichophyllae*; Vogel et al. 20030806
Dendrobium sp., sect. *Latouria*; Vogel et al. 20030847
Dendrobium sp., sect. *Oxystophyllum*; Vogel et al. 20030803

Dendrobium sp., sect. *Spatulata*; Vogel et al. 20030828
Dendrobium spp.; 14647; Vogel et al. 20030802, 20030849
Dipodium spp.; Vogel et al. 20030821, 20030835
Eria spp.; NGF 45111; Vogel et al. 20030801
Goodyera rubicunda (Bl.) Lindl.; 15423
Habenaria chloroleuca Schltr.; NGF 25685
Lepidogyne minor Schltr.; 16603; NGF 24478 (nv)
Malaxis sp.; NGF 45161
Neuwiedia veratrifolia Bl.; 14431, 14644, 15096, 15156, 16584; NGF 24478; Vogel et al. 20030833
Paphiopedilum violascens Schltr.; 16618; NGF 45147 (nv)
Phreatia sp.; Vogel et al. 20030852
Plocoglottis sp., *maculata* facies; 15055, 15087, 15159, 16565, 16594; LAE 52037; NGF 31652, 45192, 47762
Plocoglottis sp., *sakiensis* facies; 14353; NGF 25688
Plocoglottis spp.; 14665 (inflorescence terminal); Vogel et al. 20030794
Podochilus sp., *scalpelliformis* facies; 14824
Pseuderia cf. *similis* Schltr.; 14489, 15035, 15187, 15217
Pseuderia spp.; Vogel et al. 20030834, 20030848
Rhynchophreatia sp.; 14622
?*Sarcanthopsis* sp.; 15075, 16443
Spathoglottis plicata Bl.; Vogel et al. 20030820
Spathoglottis plicata Bl. ssp. *humilis* Howcroft ined.; 14397, 14452, 14524, 14631, 15163; NGF 45095, 47766
Spathoglottis portusfinschii Krzl.; Vogel et al. 20030819
Tainia sp.; Vogel et al. 20030798
Tropidia disticha Schltr.; NGF 45122; Rau 286
Tropidia sp.; Vogel et al. 20030797
Vanilla sp.; Vogel et al. 20030786, 20030858
Vrydagzynea novaguineensis J.J. Sm.; NGF 45120
genus indets.; 14352, 14897, 15069 (bottled); Vogel 20030857

PANDANACEAE (Freycinetia dets. by K.L. Huynh)
Freycinetia curvata Huynh; 14347
Freycinetia cyrtocarpa Kaneh.; 16444
Freycinetia erythrophylla Huynh; 15265
Freycinetia funicularis (Sav. ex Lam.) Merr.; 14587, 14589, 14596, 16539; Jacobs 9668; NGF 45225
Freycinetia glaucescens Huynh; 14428
Freycinetia kamialiensis Huynh; 16474
Freycinetia longiramulosa Huynh; 15259
Freycinetia macrostachya Mart.; 14593
Freycinetia mediana Huynh; 15233
Freycinetia neoforbesii Huynh; NGF 45155
Freycinetia oraria Huynh; 14414, 14528, 14731
Freycinetia pluvisilvatica Huynh; 14694
Freycinetia rubripedata Huynh; 16440
Freycinetia sachsenensis Huynh; 14384
Freycinetia takeuchii Huynh; 14351, 14552, 16475
Freycinetia tenuis Solms.; NGF 31628 (K)
Freycinetia sp., ?*marginata* Bl.; NGF 24488 (staminate)
Freycinetia spp.; 14694; LAE 52341 (550 m elev.)
Pandanus cernuifolius Merr. & Perry; 14421, 14442
Pandanus lustrorum Stone, vel aff.; 15559
Pandanus tectorius Parkinson; 14379
Pandanus sp.; SR, Kulindi, 30 m canopy trees

POACEAE
Bambusa forbesii (Ridl.) Holttum; 15360
Bambusa vulgaris Schrad.; SR, Bitoi
Centotheca latifolia (Osb.) Trin.; 15246
Chrysopogon aciculatus (Retz.) Trin.; 14438
Eragrostis cf. *brownii* (Kunth) Nees; 14532
Eragrostis tenella (L.) P. Beauv. ex Roem. & Schult.; 14542
Eriachne triseta Nees ex Steud.; 14530
Ichnanthus vicinus (F.M. Bailey) Merr.; 14816
Ischaemum mutica L.; 14439
Nastus schlechteri (Pilger) Holttum, vel aff.; 14583, 14755, 15235, 15395, 16604, 16642
Paspalum conjugatum Berg.; 14562
Paspalum orbiculare G. Forst.; 14543
Saccharum edule Hassk.; SR, cult. Lababia
Saccharum officinarum L.; SR, cult. Lababia
Sacciolepis indica (L.) Chase; NGF 45193
Urochloa mutica (Forssk.) T.-Q. Nguyen; SR, Kulindi
Zea mays L.; SR, cult. Lababia

SMILACACEAE
Smilax cf. *calophylla* Wall. ex DC.; 14655, 15016, 15561
Smilax cf. *ovatolanceolata* Koyama; 14742, 15023
Smilax sp., '*australis-zeylanica* facies'; 14567

TRIURIDACEAE
Sciaphila tenella Bl.; NGF 45094
Sciaphila sp.; Jacobs 9546; NGF 45144

ZINGIBERACEAE
Pleuranthodium sp., *Psychanthus* facies; 14459, 14957, 14963

Riedelia corallina Val.; NGF 24452
Riedelia cf. *hollandiae* Val.; 16590, 16602, 16617
Riedelia sp. A; ?15049, 16613
Riedelia sp. B; 14383, 14446, 14754, 14960, 16623
Riedelia sp. C; 14403, 14648, 15353, 16610 (14403, 14648 distr. as *Pleuranthodium tephrochlamys*); NGF 24499, 47764

DICOTS

ACANTHACEAE

Acanthus ilicifolius L., sens. lat. (spineless form); 15361
Graptophyllum sp.; LAE 52757 (nv)
Ruellia sp. (*Leptosiphonium*); 15252
Strobilanthes sp.; 15269

ACTINIDIACEAE

Saurauia sp., aff. *schumanniana* Diels; 14356, 14417, 14557, 14579, 14623, 14787, 14918, 15032, 15045, 15443; NGF 25670, 47765; Rau 565

ANACARDIACEAE

Buchanania macrocarpa Laut.; 15221, 16589; NGF 24484
Campnosperma brevipetiolata Volk.; SR, Tabali River
Campnosperma montanum Laut.; 15066; NGF 39416, 45110
Euroschinus papuanus Merr. & Perry; NGF 25666
Semecarpus aruensis Engl.; NGF 45151
Semecarpus australiensis Engl.; Jacobs 9646; NGF 24485
Semecarpus cf. *brachystachys* Merr. & Perry; 14486, 14614, 15005, 15358; NGF 28085 (K)
Semecarpus bracteatus Laut., vel aff.; 14821, 14948, 15046
Semecarpus cassuvium Roxb.; Jacobs 9559; LAE 52336
Semecarpus forstenii Bl.; Jacobs 9594
Semecarpus sp., aff. *?schlechteri* Laut.; NGF 39436 (nv)

ANNONACEAE

Cyathocalyx cf. *polycarpum* C.T.White (*papuanus-polycarpum* group); 14819, 14910, 15402, NGF 24489 (nv), 28075 (K, nv), 31634 (K, nv), 31642 (K, nv), 45141 (nv)
Goniothalamus aruensis Scheff.; NGF 25663, 45160
Goniothalamus sp.; Jacobs 9539
Haplostichanthus longirostris (Scheff.) Heusden; NGF 25002 (K)
Mitrella sp. (*Fissistigma* s. lat.); 14693, 14912, 15388
?Petalolophus megalopus K. Sch., vel aff.; 14652, 15167, 15177 (all nos. without flowers, possibly *Pseuduvaria*)
Polyalthia cf. *oblongifolia* Burck.; NGF 25006 (K), 31638 (K)
Polyalthia spp.; 14865, 16631; Jacobs 9666, 9688; NGF 24456
Pseuduvaria ?beccarii (Scheff.) Sincl.; Conn et al. 203, 247; NGF 45137; Rau 613
Pseuduvaria sp., aff. *?filipes* Laut. & K. Sch.; 14822
Uvaria sp., *cordata-rosenbergiana* facies; 14859, 14913, 14919
Xylopia sp., aff. *peekelii* Diels; 14941, 15580
genus indet.; LAE 52034

APOCYNACEAE

Alyxia acuminata K. Sch., sens. lat.; 14698, 14766, 14977, 14985, 15025, 15145, 16563; LAE 51687, 68554; NGF 28072 (K)
Anodendron oblongifolium Hemsl.; 15433
Cerbera floribunda K. Sch.; 14516, 15344
Cerbera manghas L.; 15134
Hoya lauterbachii K. Sch.; NGF 22888 (nv)
Hoya sp. A; 14720, 14933, 15206, 15240
Hoya sp. B; 15425
Ichnocarpus wariana (Schltr.) Middleton; Jacobs 9687
Melodinus cf. *novoguineensis* (Wernh.) Pichon; 14679
Ochrosia coccinea (Teijsm. & Binn.) Miq.; 14422, 15040
Parsonsia alboflavescens (Dennst.) Mabberley; 14667, 14839, 15133, 15135
Parsonsia buruensis (Teijsm. & Binn.) Boerl.; 15137
Parsonsia curvisepala K. Sch.; 14718, 14853, 14971; NGF 25672, 45128
Sarcolobus retusus K. Sch.; 14354, 14606, 15138, 16566; Bellamy 5; Conn 174; Jacobs 9680; NGF 45114
Tabernaemontana aurantiaca Gaud.; 14395
Tabernaemontana pandacaqui Lam.; 14858, 15224
genus indet.; 15212

ARALIACEAE

Mackinlaya celebica (Harms) Philipson; SR, near Cape Roon

Mackinlaya schlechteri (Harms) Philipson; 14671, 15094, 15190, 15572; NGF 45164
Osmoxylon boerlagei (Warb.) Philipson; 15264
Plerandra stahliana Warb.; NGF 62051
Schefflera sp.; 14797, 14804, 14833

ARISTOLOCHIACEAE
Aristolochia momandul K. Sch.; 14394

ASTERACEAE
Adenostemma lavenia (L.) O. Ktze.; 15248
Bidens pilosa L. var. *minor* (Bl.) Sherff; 14436
Erigeron sumatrensis Retz.; 15204
Wedelia biflora (L.) DC.; SR, near Tabali

BEGONIACEAE
Begonia sp., *brachybotrys-pseudolateralis* facies; 15424

BIGNONIACEAE
Dolichandrone spathacea (L.f.) K. Sch.; 15268
Pandorea pandorana (Andr.) Steen.; 14852
Tecomanthe dendrophila (Bl.) K. Sch.; NGF 24467, 39434

BIXACEAE
Bixa orellana L.; SR, cult. Lababia

BURSERACEAE
Canarium lamii Leenh.; NGF 28060 (K)
Canarium salomonense Burtt; NGF 28092
Canarium vitiense A. Gray; Jacobs 9672
Canarium sp., close to *vitiense* A. Gray; NGF 31648 (K)
Haplolobus floribundus (K. Sch.) H.J. Lam; Jacobs 9673; LAE 52055; NGF 24468

CANNABACEAE
Gironniera celtidifolia Gaud.; 14404, 14708, 14779, 14921, 15378, 16640; LAE 51667; NGF 25680, 47768
Trema cannabina Lour.; 14483, 15064, 15173, 15346; Conn et al. 185, 187; NGF 31633 (K); Rau 563

CARICACEAE
Carica papaya L.; SR, cult. Lababia

CASUARINACEAE
Gymnostoma papuanum (S. Moore) L.A.S. Johnson; 14444, 14778, 14780; NGF 25665

CELASTRACEAE
Bhesa archboldiana (Merr. & Perry) Ding Hou; 15042, 15056, 15074 (distr. as *B. robusta*), 15571
Loeseneriella macrantha (Korth.) A.C. Smith; Jacobs 9619
Lophopetalum torricellense Loes.; 16600; LAE 51684
Salacia chinensis L.; 16425
Salacia erythrocarpa K. Sch.; LAE 52316
Salacia papuana (Loes.) Ding Hou; LAE 52320
Salacia sp.; NGF 45109 (carpological coll. missing, sheet sterile)

CHRYSOBALANACEAE
Hunga papuana (Baker f.) Prance; 14922, 14929, 14940, 15584
Maranthes corymbosa Bl.; 14556, 14712, 14920, 14937, 14942, 14968; NGF 31644 (K)
Parastemon versteeghii Merr. & Perry; 15021; NGF 45157
Parinari papuana C.T. White ssp. *whitei* Prance; 14885, 15015; Jacobs 9583; NGF 28063, 44202

CLUSIACEAE (Calophyllum dets. by P. Stevens)
Calophyllum goniocarpum Stevens; 14981; NGF 24474
Calophyllum inophyllum L.; 14535, 15111; Swaine 66
Calophyllum morobensis Stevens; Johns sn (LAE sheet 129181, nv); NGF 24490 (nv)
Calophyllum papuanum Laut.; 14892, 14905, 15347, 16564; LAE 52312; NGF 24487
Calophyllum streimannii Stevens; LAE 52755; NGF 24285, 24491, 28084 (K)
Calophyllum sp.; 14535
Garcinia cf. *assugu* Laut.; 16632
Garcinia celebica L.; 14416, 14419, 16413
Garcinia dulcis (Roxb.) Kurz; 15406; NGF 28066 (K)
Garcinia hunsteinii Laut.; 15050; NGF 24458
Garcinia latissima Miq.; NGF 24447, 28073
Garcinia cf. *ledermanii* Laut.; 14333, 14348, 14617, 14734, 14867, 15404
Garcinia maluensis Laut.; 15412, 16574; NGF 31646 (K)
Garcinia sinuata Stevens; 14886, 14888, 15169, 15192, 15398, 16583; NGF 24449, 45165
Garcinia sp., *assugu-maluensis* facies; 14651, 14689, 14713, 14729, 14830, 14863, 14890, 14955, 14987, 15001, 15199, 16436; LAE 52761
Garcinia sp., aff. ?*sabangensis* Laut.; 14433, 14769, 14808, 16641

Garcinia sp.?nov.;*ledermanii* facies but not *Cambogia*; 15379, 15409; NGF 24455
Garcinia spp.; 14325, 14799
Mammea papyracea Stevens; NGF 39414

COMBRETACEAE
Lumnitzera littorea (Jack) Voight; 14378, 14902; LAE 52059; NGF 39092, 44153
Terminalia canaliculata Exell; 15256
Terminalia catappa L.; SR, Lababia
Terminalia rubiginosa K. Sch.; LAE 52043
Terminalia sepicana Diels; NGF 39412

CONVOLVULACEAE
Erycibe cf.*hellwigii* Prain; 14585, 14682; LAE 51691; NGF 24471, 24498, 45100 (keys between *E. carrii* and *E. puberula*)
Ipomoea batatas (L.) Lamk; SR, cult. Lababia
Ipomoea pes-caprae (L.) R. Br.; 14544
Ipomoea pes-caprae (L.) R. Br. ssp. *brasiliensis* (L.) Ooststroom; NGF 22879
Merremia peltata (L.) Merr.; SR, Tabali River

CUCURBITACEAE
Cucumis sativus L.; SR, cult. Lababia

CUNONIACEAE
Ceratopetalum succirubrum C.T. White; sn (sterile)
Weinmannia fraxinea (D.Don) Miq.; 15053, 15054, 15150

DILLENIACEAE
Tetracera nordtiana F.v.M. var. *moluccana* (Mart.) Hoogl.; 15004

DIPTEROCARPACEAE
Anisoptera thurifera (Blanco) Bl. ssp. *polyandra* (Bl.) Ashton; SR, throughout KWMA; LAE 51965, 52039
Hopea cf. *glabrifolia* C.T.White; 14620

EBENACEAE
Diospyros cf.*elliptica* (J.R. & G. Forst.) Green; NGF 28070 (K), 31631 (K), 31632 (K), 31647 (K), 45168, 45169 (some inflorescences cymose but most simple)
Diospyros ferrea (Willd.) Bakh., sens. lat.; 14366, 14555, 14559, 14574, 14715, 14847, 14943, 14975, 15033, 15439 (preceding nos. distr. as *D. elliptica* but inflorescence not cymose), 15387; NGF 39096
Diospyros novoguineensis Bakh.; 15371, 16417; LAE 51679; NGF 24457, 28078 (K), 45148
Diospyros papuana Val. ex Bakh.; NGF 45135
Diospyros cf. *sogeriensis* Bakh.; 15029, 15098, 15381; NGF 24450, 24500
Diospyros sp., ?*'ferrea* group'; NGF 25010 (K)

ELAEOCARPACEAE
Aceratium parvifolium Schltr.; NGF 31627 (K)
Elaeocarpus dolichostylus Schltr. ssp. *dolichostylus*; NGF 45138
Elaeocarpus ledermannii Schltr.; LAE 51670, 52758; NGF 44209, 45129
Elaeocarpus sphaericus (Gaertn.) K. Sch.; 14418, 14548
Elaeocarpus sp.,*'sepikanus* group'; LAE 52048
Elaeocarpus sp.?nov.5, aff.*miegei* fide Coode; LAE 52295; NGF 25668, 28089
Sloanea pulchra (Schltr.) A.C. Smith ssp. *morobensis* Coode; NGF 25005 (K), 28067 (K), 28096 (K)
Sloanea sogerensis Bak. f., sens. lat.; 14695; Conn et al. 197; NGF 28065 (K), 31649 (K), 45117 (most colls. represent the*'schumannii* facies', cf. Coode 1981)

ERICACEAE
Paphia megaphylla Stevens ined.; 15383B, 16644

ERYTHROXYLACEAE
Erythroxylum ecarinatum Burck; 14763, 14768, 14772, 14786, 14796, 14992, 15039

EUPHORBIACEAE sens. lat. (including Phyllanthaceae)
Actephila lindleyi (Steud.) Airy Shaw; 14386, 14456, 14639, 14677, 15030, 15354, 16592; Jacobs 9538; LAE 52031; NGF 45136
Antidesma moluccanum Airy Shaw var. *moluccanum*; 15417
Antidesma polyanthum K. Sch. & Laut.; 14856, 15014
Antidesma cf. *sarcocarpum* Airy Shaw; 14972; NGF 28061 (K)
Antidesma sphaerocarpum Muell. Arg.; 14474, 14493, 15038, 15414, 15568; LAE 52051; NGF 45167
Aporosa brassii Mansf.; NGF 45133
Aporosa praegrandifolia (S.Moore) Schot; 15168; LAE 52049; NGF 45134, 45171
Breynia cernua (Poir.) Muell. Arg.; 14423, 14580, 14834, 14967; NGF 47782
Claoxylon aff. *ledermannii* Airy Shaw var. *ledermannii*; 14738, 14751 (nos. distr. as

group '*Purpurescentia*'), 15386, 15416, 16587; LAE 51669
Cleistanthus pedicellatus Hook. f.; 14749 (distr. as *Kairothamnus phyllanthoides*)
Cleistanthus sp., cf. *myrianthus* (Hassk.) Kurz; 16621; NGF 44608
Cleistanthus sp., aff. *pedicellatus* Hook. f.; 14473 (leaves obtuse, capsule lobed)
Codiaeum variegatum (L.) Bl. var. *moluccanum* (Decne) Muell. Arg.; Jacobs 9596; NGF 45143
Croton cf. *choristadenius* K. Sch.; 14747, 15151, 16442; NGF 45101, 45102
Endospermum cf. *labios* Schodde; 15255
Euphorbia hirta L.; 14435
Glochidion granulare Airy Shaw; 16412
Glochidion sp.; 14571
Kairothamnus phyllanthoides (A. Shaw) A. Shaw; LAE 52046, 73372; NGF 24462, 44211, 44602, 45108
Macaranga angustifolia Laut. & K. Sch.; 15375; NGF 25674
Macaranga bifoveata J.J. Smith; 14525, 14582, 14586, 14807, 15359, 16431
Macaranga polyadenia Pax & Hoffm.; SR, passim
Macaranga tanarius (L.) Muell. Arg.; NGF 44609 (nv)
Manihot esculenta Crantz; SR, cult. Lababia
Phyllanthus cf. *effusus* S. Moore; 14321, 14387
Phyllanthus sp.; NGF 45177
Pimelodendron amboinicum Hassk.; 14788, 15405; NGF 31640 (K), 31643 (K)
Suregada glomerulata (Bl.) Baill.; 14367, 15013, 15034

FABACEAE

Abrus pulchellus Thwaites ssp. *pulchellus*; NGF 62046
Arachis hypogaea L.; SR, cult. Lababia
Archidendron lucyi F.v.M.; 15436
Archidendron molle (K. Sch.) de Wit, vel aff.; 16524; Jacobs 9621; LAE 52760; NGF 28090 (K)
Archidendron ptenopum Verdc.; 16616; NGF 44212
Archidendron sp.; 15022
Caesalpinia crista L.; NGF 22896
Crotalaria retusa L.; 15376
Dahlbergia candenatensis (Dennst.) Prain; 14882
Derris indica (Lam.) J.J. Bennett; 14619, 15123; NGF 25686 (nv)
Derris trifoliata Lour.; SR, Tabali
Desmodium umbellatum (L.) DC.; 14361, 14450, 15117
Inocarpus cf. *papuanus* Kostermans; 14719
Intsia bijuga (Colebr.) O. Kuntze; SR, Bulili shoreline
Macropsychanthus lauterbachii Harms; SR, Saia River
Maniltoa sp., aff. *schefferi* K. Sch. & Hollrung; 14318, 15582; sp. E in Verdcourt (1979)
Mucuna schlechteri Harms; 14746, 14966, 15377; Jacobs 9640; NGF 25673, 45096
Ormosia calavensis Azaola ex Blanco; 14958
Sophora tomentosa L. ssp. *tomentosa*; Martin 2520; NGF 47774
Vigna unguiculata (L.) Walp.; SR, cult. Lababia

FAGACEAE

Lithocarpus vinkii Soepadmo; 14317, 14517 (nos. distr. as *L. celebicus*); NGF 24492, 31622 (K), 44213

GENTIANACEAE

Fagraea amabilis S. Moore; 14462 (610 m)
Fagraea berteroana A. Gray ex Wall.; Jacobs 9542; LAE 52314 (nv)
Fagraea ceilanica Thunb.; 14369, 14598, 15020
Fagraea racemosa Jack ex Wall.; 14760, 14908, 14979, 15340; Jacobs 9622; LAE 51665, 52041, 52335, 68510; NGF 22885 (K)

GESNERIACEAE

Aeschynanthus cf. *kermesinus* Schltr.; 14504
Aeschynanthus cf. *leptocladus* C.B. Clarke; 14461
Boea lawesii H.O. Forbes; LAE 62047
Boea mollis Schltr.; NGF 47781
Cyrtandra schumanniana Schltr., vel aff.; LAE 51682
Cyrtandra sp., sect. *Centrosiphon*; NGF 45173
Cyrtandra sp., sect. *Loxophyllum/Phaeotrichium*; 14458, 14485

GOODENIACEAE

Scaevola oppositifolia R. Br.; SR, Kulindi
Scaevola sericea Vahl; 14363

ICACINACEAE

Platea latifolia Bl.; 15421
Rhyticaryum longifolium K. Sch. & Laut.; 14653, 14664, 14877; Jacobs 9671

LAMIACEAE

Callicarpa longifolia Lamk.; NGF 22883 (K)
Gmelina ledermanni H.J. Lam; 14365, 14487,

14924, 15026, 15114, 15343; Jacobs 9536; NGF 28077 (K); Rau 609
Leucas flaccida R. Br.; NGF 25684
Plectranthus sp., aff. *?parviflorus* Willd.; 14437 (does not key)
Premna serratifolia L.; 14441, 14893; NGF 47784

LAURACEAE

Actinodaphne nitida Teschn.; NGF 31637 (K)
Cassytha filiformis L.; 14527, 14540
Cinnamomum eugenoliferum Kosterm.; NGF 45130
Cryptocarya cf. *densiflora* Bl.; LAE 52315
Cryptocarya laevigata Bl.; 14709, 14947, 14953, 15153, 16588, 16608
Cryptocarya multipaniculata Teschn.; 15241
Cryptocarya novoguineensis Teschn.; 16633; NGF 28086 (K)
Cryptocarya pulchella Teschn., vel aff.; 15578
Cryptocarya sp.; 14476
Endiandra engleriana Teschn.; NGF 28068 (K)
Endiandra forbesii Gamble; NGF 39098, 45187
Litsea sp., *collina* facies; 15348
Litsea sp., *guppyi* facies; 14703, 14978, 15244; NGF 24472
Persea americana Mill.; SR, cult. Lababia

LECYTHIDACEAE

Barringtonia apiculata Laut.; 15113; LAE 52053; NGF 28081 (K)
Barringtonia asiatica (L.) Kurz; SR, Lababia, also several colls. Lasanga
Barringtonia lumina Jebb ined.; SR, Saia River (un common); NGF 45145
Barringtonia pinifolia Jebb ined.; 14560, 14576, 14681, 14704 (distr. as *B. calyptrocalyx* cf. var. *boridiensis*), 16438, 16585; Jacobs 9550
Barringtonia racemosa (L.) Spreng.; 15250
Barringtonia sp., aff. *?acutangula* (L.) Gaertn.; 15364
Barringtonia sp. A; NGF 25676, listed as uniden tified 'group 2' in Jebb (1991)
Barringtonia sp. B; 14866 (distr. as *B. calyptrata* but not that species)

LINACEAE

Hugonia jenkinsii F.v.M.; 14632, 15112, 15160; Ja cobs 9603; NGF 24470

LOGANIACEAE

Geniostoma rupestre J.R. & G. Forst.; 16597; Conn et al. 175, 178, 186, 207; Jacobs 9597, 9613; NGF 24486, 47763; Rau 283, 590, 606, 608, 614, 617
Geniostoma rupestre J.R. & G. Forst. var. *rupestre*; 14448, 14480, 14714, 14727, 14752, 14832, 14838, 14855, 14931, 15072, 15442
Neuburgia corynocarpa (A. Gray) Leenh.; 15245, 15258, 15363
Strychnos minor Dennst.; 14316, 15024, 15027

LORANTHACEAE

Amyema scandens (Tiegh.) Danser ssp. *scandens*; 16432
Decaisnina hollrungii (K. Sch.) Barlow; 14551, 16421; NGF 45196
Dendrophthoe curvata (Bl.) Miq.; 14430, 14529
genus indet.; NGF 47761

MAESACEAE

Maesa haplobotys F.v.M.; 14923, 15238, 15384, 16620

MALVACEAE

Brownlowia argentata Kurz; 15275
Commersonia bartramia (L.) Merr.; 14410, 14460, 14823, 15047, 15342; Swaine 10
Heritiera littoralis Ait.; 15249; LAE 52333
Hibiscus tiliaceus L.; SR, Tabali River and Lababia beachfront
Kleinhovia hospita L.; SR, Lababia
Microcos sp.; NGF 28069 (K)
Sida cordifolia L.; 14434
Sterculia cf. *lepidostellata* Milbr.; 14820
Sterculia morobeensis Tantra; Jacobs 9663; NGF 28093 (K)
Sterculia schumanniana (Laut.) Mildbr.; 14721; Conn et al. 211; LAE 62045; NGF 28076 (K)
Sterculia sp. ?nov., aff. *shillinglawii* F.v.M.; 14591, 14743, 14803, 15181
Sterculia sp. nov., fide Tantra (1976); Jacobs 9639
Thespesia populnea (L.) Sol. ex Correa; SR, Lababia

MELASTOMATACEAE

Astronidium morobiense Maxw.; 15351, 15560, 16223 (dets. S.S. Renner); NGF 25658 (nv) and 45180 (nv) could be this sp.
Medinilla sp., aff. *tenuipedicellata* Bak. f.; 14795
Medinilla spp.; 15365, 16615
Melastoma malabathricum L. ssp. *malabathricum*; 14372, 15121 (distr. as *M. af fine* D. Don)
Poikilogyne sp.; NGF 45232

MELIACEAE

Aglaia brownii C.M. Pannell; 14911; NGF 24446
Aglaia cf. *rimosa* (Blanco) Merr.; 14666, 15076
Aglaia sapindina (F.v.M.) Harms; 14427, 15230, 15266, 15366, 15574, 16222; Jacobs 9576, 9607; NGF 45140; Warete-Namorong 7
Aglaia tomentosa Teijsm. & Binn.; 15407, 15422, 16643
Aglaia sp., aff. ?*agglomerata* Merr. & Perry; 14332, 14482, 15179 (distr. as *A. silvestris*, vel aff.), 15419, 15576; NGF 45183
Aglaia sp., aff. ?*sapindina* (F.v.M.) Harms; 14393, 15175, 15191, 15350; LAE 52054
Aphanamixis polystachya (Wall.) R.N. Parker; 15434
Chisocheton lasiocarpus (Miq.) Val.; 15257, 15429
Chisocheton lasiocarpus (Miq.) Val. entity *'schlechteri'*; 15041, 15104, 15161, 15176, 16599; LAE 52343
Chisocheton lasiocarpus (Miq.) Val. entity *'weinlandii'*; LAE 62059
Chisocheton sapindinus Stevens; 14336, 15411, 15574, 16414; NGF 45140
Dysoxylum arborescens (Bl.) Miq.; LAE 51686
Dysoxylum papuanum (Merr. & Perry) Mabb.; LAE 52319
Vavaea amicorum Benth.; NGF 24482
Xylocarpus granatum Koen.; 14634, 14899

MEMECYLACEAE

Memecylon sp., *sepicana-schraderbergense* facies; 14670; NGF 25003

MENISPERMACEAE

Hypserpa polyandra Becc. var. *polyandra*; 14553, 14744, 15078; Jacobs 9653; LAE 51673; NGF 24473
Macrococculus pomiferus Becc.; LAE 62057

MONIMIACEAE

Kairoa suberosa Philipson; 15430
Kibara oblongata Philipson, vel aff.; 14334, 15012
Levieria nitens Perkins; NGF 24439 (nv)
Steganthera hirsuta (Warb.) Perkins; 14575, 14706, 15164; NGF 25687

MORACEAE

Artocarpus communis J.R. & G. Forst.; SR, Tabali River
Ficus adenosperma Miq.; 14359
Ficus ampelas Burm. f.; 14565, 14581, 14592, 14726; NGF 45118
Ficus arfakensis King; 15263
Ficus benjamina L.; LAE 52300, 68522; NGF 44154
Ficus calodictya Summerh.; 14962
Ficus gul Laut. & K. Sch.; 15019, 15222, 15272
Ficus hystricicarpa Warb.; 14687, 14964
Ficus irritans Summerh.; 14691, 14970
Ficus itoana Diels; 14626
Ficus odoardi King; NGF 51671
Ficus pachystemon Warb.; 14491, 14569, 14584, 14673, 14696, 15210, 15401, 15569B (some nos. merging with *F. subtrinervia* Laut. & K. Sch.)
Ficus rhizophoriphylla King; NGF 28087 (K)
Ficus trachypison K. Sch. var. *pallida* Corner; LAE 52759
Ficus wassa Roxb.; NGF 31645 (K)
Parartocarpus venenosus (Zoll. & Mor.) Becc. ssp. *papuanus* (Becc.) Jarrett; NGF 25001 (K)
Prainea papuana Becc.; NGF 45150

MYRISTICACEAE

Gymnacranthera farquhariana (Hook. f. & Th.) Warb. var. *zippeliana* (Miq.) R. Schouten; 14337, 14680, 14872, 14945, 14954A, 15410, 16625, 16626, 16627, 16628
Horsfieldia hellwigii (Warb.) Warb.; 15435
Horsfieldia laevigata (Bl.) Warb. var. *laevigata*; LAE 51683, 52030
Horsfieldia pilifera Markgrf.; Jacobs 9609, 9609A; LAE 52756; NGF 28080 (nv)
Horsfieldia sylvestris (Houtt.) Warb.; 15271
Horsfieldia tuberculata (K. Sch.) Warb. var. *tuberculata*; 14549
Myristica chrysophylla Sincl. ssp. *chrysophylla*; 14735, 14951, 15438; Jacobs 9574; LAE 52032, 52062; NGF 45166
Myristica chrysophylla Sincl. cf. ssp. *entrecasteauxensis* (Sincl.) de Wilde; 14335, 14602, 15018, 15082, 15130; LAE 52029
Myristica cornutiflora Sincl. ssp. *elegans* de Wilde; 14590, 14860
Myristica filipes de Wilde; 14566, 14700, 14935; Conn et al. 182, 281 (nv); LAE 51668, 52061 (nv); NGF 45115, 45116
Myristica globosa Warb.; Jacobs 9572
Myristica markgraviana A.C. Smith; LAE 52027
Myristica sulcata Warb.; Jacobs 9685; LAE 52028
Myristica tubiflora Bl.; NGF 45142
Myristica umbrosa Sincl.; 14600, 15188; LAE 52033, 52047, 52287, 52332; NGF 25659

Myristica sp. ?nov.; 14340, 14661, 15011, 15109, 15397, 16424, 16573
Myristica sp.; 16591

MYRSINACEAE

Aegiceras corniculatum (L.) Blanco; 15274
Conandrium polyanthum (Laut. & K. Sch.) Mez; 14338, 14447, 14570, 14761, 14774, 14825; LAE 52040, 52050
Discocalyx kaoyae Pipoly & Takeuchi ined.; 16441
Discocalyx orthoneura K. Sch.; NGF 24451
Discocalyx sp.; Jacobs 9584 (nv)
Fittingia tubiflora Mez; 14425, 14429, 14445, 14572, 14991, 14997, 14999, 16580, 16582, 16596, 16622; LAE 52302
Fittingia urceolata Mez; Conn et al. 284; Jacobs 9644; NGF 45139, 45163; Rau 291
Myrsine leucantha (K. Sch.) Pipoly; NGF 24429, 45235 (nv)
Myrsine rawacensis A. DC.; 14604, 15562; NGF 44603
Myrsine sp., (*Rapanea ?lamii* Sleumer); 14469

MYRTACEAE

Decaspermum bracteatum (Roxb.) A.J. Scott var. *bracteatum*; 14611, 14770, 14782, 14792, 15007, 16567; LAE 52322
Eucalyptopsis papuana C.T. White; LAE 52296, 52331, 52334; NGF 28097 (K)
Lophostemon suaveolens (Sol. ex Gaertn.) P.G. Wilson & J.T. Waterh.; 15116
Myrtella beccarii F.v.M.; 14349, 14380, 14814, 15583; Bellamy 6; Jacobs 9650; LAE 52292, 72469; NGF 44151; Paijmans 1564; Swaine 8; Watt sn
Octamyrtus insignis Diels; NGF 25018
Psidium guajava L.; SR, cult. Lababia
Rhodamnia blairiana F.v.M. var. *propinqua* (C.T. White) A.J. Scott; 14405, 14841; NGF 44215
Rhodomyrtus pinnatinervis C.T. White; LAE 52304 (600 m)
Syzygium buettnerianum (K. Sch.) Niedenzu, vel aff.; Jacobs 9677; LAE 52297
Syzygium claviflorum (Roxb.) Cowan & Cowan; 14477
Syzygium effusum (A. Gray) C. Muell., sens. lat.; 14315; NGF 24483, 45159
Syzygium cf. *flavescens* (Ridley) Merr. & Perry; 14341
Syzygium furfuraceum Merr. & Perry; 14740, 14944; NGF 31635 (K), 31650 (K)
Syzygium leptoneurum Diels; 15194; NGF 39095, 47770; Swaine 9
Syzygium longipes Merr. & Perry; 14388
Syzygium nutans (K. Sch.) Merr. & Perry; Jacobs 9629; NGF 24459
Syzygium richardsonianum Merr. & Perry, vel aff.; 14733, 14954B, 15084, 15144, 15399; LAE 51663; NGF 24476, 39431
Syzygium subcorymbosum Merr. & Perry; LAE 52289, 52317; NGF 45106
Syzygium thornei Hartley & Perry; NGF 24428
Syzygium trivene (Ridley) Merr. & Perry; 14381, 14402, 14413, 14484, 14518, 14588, 14618, 14688, 14737, 14851, 14969, 14994, 14998, 15396, 15437, 15569A, 16434, 16581; Jacobs 9617, 9645; LAE 51664; NGF 24497, 25657, 39419, 44155
Syzygium cf. *trivene* (Ridley) Merr. & Perry; 14773, 14811, 14835, 14845; NGF 25669 (nonconformist nos. with persisting bracts but cf. Hartley & Perry 1973: 213)
Syzygium viburnoides Diels; 14479
Syzygium xylopiaceum (Diels) Merr. & Perry; Jacobs 9654; LAE 52291
Syzygium sp., =*Acmena acuminatissima* (Bl.) Merr. & Perry; NGF 28095 (K)
Syzygium sp., aff. *malaccense* (L.) Merr. & Perry; 15349
Syzygium sp., aff. ?*rostratum* (Bl.) DC.; 15127
Syzygium sp. ?nov.; aff. *pyriforme* Merr. & Perry; 15382, 16607
Syzygium sp. ?nov., aff. couplet 57a or 88a; 14723, 14724, 14725
Syzygium sp.; 15095
Syzygium sp.; 15428
Tristaniopsis macrosperma (F.v.M.) P.G. Wilson & J.T. Waterh.; 14343, 15058, 15131, 15579; NGF 24464, 44607; Vinas & Kairo 295
Tristaniopsis oreophila (Diels) P.G. Wilson & J.T. Waterh.; NGF 42638
Xanthostemon petiolatus (Val.) P.G. Wilson; 15147, 15345

NEPENTHACEAE

Nepenthes neoguineensis Macf.; 14453, 14697; 14837 (distr. as *N. mirabilis*), 15573, 16435; Jacobs 9651, 9658; LAE 52313; NGF 24461, 24463; Rau 571; Watt 31

NYCTAGINACEAE

Pisonia longirostris Teijsm. & Binn.; LAE 62049

NYSSACEAE

Mastixia kaniensis Melch. ssp. *kaniensis*; LAE 52339

OCHNACEAE

Brackenridgea forbesii Tieg.; 16629; NGF 25004 (K), 28091 (K), 44205

Schuurmansia henningsii K. Sch.; 15220; NGF 31620 (K), 39413, 39430

OLACACEAE

Anacolosa papuana Schellenb.; 16624

OLEACEAE

Chionanthus ramiflorus Roxb.; LAE 62048

Chionanthus rupicolus (Lingelsch.) Kiew; 14385, 14607, 14672, 14883, 15149 (distr. as *C. ramiflorus*); Bellamy 9; LAE 52325; NGF 24465; Rau 572

Chionanthus sessiliflorum (Hemsl.) Kiew; LAE 62060

Jasminum schumannii Lingelsh.; LAE 62050

OXALIDACEAE

Averrhoa bilimbi L.; 14408, 14817

PANDACEAE

Galearia celebica Koord. var. *celebica*; 14660, 14927, 15037, 15209, 15400, 15403; LAE 51672

PASSIFLORACEAE

Adenia heterophylla (Bl.) Koord. ssp. *heterophylla*; NGF 62062

Passiflora foetida L.; SR, Lababia

PENTAPHYLACACEAE

Eurya sp./?spp.; 14463; NGF 24431 (nv), 45234 (nv)

PIPERACEAE

Piper aduncum L.; 15273

Piper celtidiforme Opiz.; 15243

Piper lessertianum (Miq.) C. DC.; 14432, 14455, 14828

Piper macropiper Pennant; 14561

Piper novoguineense Warb.; 14345

Piper pseudoamboinense C. DC.; NGF 25678

Piper versteegii C. DC.; LAE 51689

Piper sp.; 14314

POLYGALACEAE

Eriandra fragrans Royen & Steen.; 14376, 14683, 14777, 14871, 14873, 14874, 14875, 14946, 15239, 15380

Polygala paniculata L.; 14375

POLYOSMACEAE

Polyosma sp., aff. *forbesii* Val.; 14329, 14466, 14884, 14894, 15090, 15413; NGF 52337

PROTEACEAE

Bleasdalea papuana (Diels) Domin; LAE 52344 (550 m)

Finschia chloroxantha Diels; 14364, 15146; LAE 52060, 52345; NGF 45119, 47783

Grevillea papuana Diels; 14449, 14521

Helicia obtusata Sleum.; LAE 51685, 52038, 52288, 52298

Stenocarpus moorei F.v.M.; 14526, 14534, 14984, 14989, 15394, 16426; LAE 52044, 52294, 52326; NGF 39091

RHAMNACEAE

Alphitonia excelsa (Fenzl) Reiss. ex Endl. (sensu Schirarend); 15335, 15374; Jacobs 9667

Alphitonia macrocarpa Mansf.; 15408; NGF 25664

RHIZOPHORACEAE

Bruguiera gymnorrhiza (L.) Lamk; 14377

Ceriops tagal (Perr.) C.B. Rob.; 15148B; Bellamy 16; LAE 68539

Gynotroches axillaris Bl.; 15091, 15570; Jacobs 9684; NGF 24494, 31641 (K)

Rhizophora apiculata Bl.; LAE 68537, 68543

Rhizophora stylosa Griff.; 15143

ROSACEAE

Rubus fraxinifolius Poiret; LAE 62052

RUBIACEAE

Anthorrhiza echinella Huxley & Jebb; 14470 (distr. as *Myrmecodia tuberosa*); NGF 39094, 45103

Atractocarpus macarthurii (F.v.M.) Puttock; Jacobs 9580

Atractocarpus sp., =*Randia sphaerocarpa* K. Sch. & Laut.; NGF 24454

Atractocarpus sp.; 14342, 14370, 14472, 14676, 14707, 14711, 14928, 15081, 15369, 15370; NGF 25009 (K), 39093, 45152, 47777

Canthium sp., sens. lat.; 14654, 15100, 15136, 15237; Heads 268; NGF 39429, 45158, 47760, 47772; Rau 287

Gardenia lamingtonii F.M. Bailey; NGF 45185

Gardenia sp. nov.; 14864, 15101, 15558, 15575; NGF 25675, 45156

Gynochthodes aff. *verticillata* (Val.) Hosokawa; 14692, distr. as *'Randia'*

Hedyotis corymbosa (L.) Lam.; 14541

Hedyotis pubescens Val.; NGF 45176

Hydnophytum hellwigii Warb.; 15207; NGF 25662, 45105
Hydnophytum cf. *radicans* Becc.; LAE 62058
Hydnophytum sp. A; 14399
Hydnophytum sp. B; 14949; Jacobs 9669
Ixora sp. A; 14322, 14371, 14392, 14625, 14628, 14854, 14887, 14926, 14936, 14938, 14976, 15000, 15003, 15119, 15341; LAE 51675, 52042, 62061; NGF 24495, 31630 (K), 45179
Ixora sp. B; 14481, 15009, 15105, 15385, 15581, 16420, 16609
Lasianthus sp., *papuanus-chlorocarpus* facies; 15178, 15197
Morinda citrifolia L.; 14424, 15368; Conn 320; Jacobs 9702; LAE 52293; NGF 47769
Morinda umbellata L.; 14478, 14635
Mussaenda ferruginea K. Sch.; 14757
Myrmecodia tuberosa Jack; 14730
Nauclea orientalis (L.) L.; 15254
Nauclea tenuiflora (Havil.) Merr.; NGF 22886 (K)
Neonauclea clemensii Merr. & Perry; NGF 22489
?Porterandia, =*Randia ixoraeflora* Wernh.; Jacobs 9689; NGF 51688, 52057
Psychotria amplithyrsa Val.; 15166; NGF 51680
Psychotria archboldii Sohmer var. *archboldii*; 14904, 14906, 15028, 16415, 16422
Psychotria bulilimontis var. *aestuarii* Takeuchi; 14990, 14993, 14995, 15002
Psychotria bulilimontis Takeuchi var. *bulilimontis*; 16416, 16428
Psychotria croftiana Sohmer; 14490, 15048, 15139, 15566, 16430B, 16578; Jacobs 9636
Psychotria diplococca Laut. & K. Sch. var. *diplococca*; 15432
Psychotria cf. *leiophloea* Merr. & Perry; 15234, 15236, 16430A
Psychotria leonardii Merr. & Perry; 15057
Psychotria leptothyrsa Miq. var. *leptothyrsa*; 14492; Jacobs 9567
Psychotria membranifolia Bartl. ex DC.; 14488, 14750, 14831, 15184, 15203, 16575, 16577, 16606
Psychotria micralabastra (Laut. & K. Sch.) Val., 15068, 15339, 15426, 15427; NGF 31651 (K)
Psychotria micrococca (Laut. & K. Sch.) Val.; Conn et al. 278 (nv)
Psychotria olivacea Val.; 14771, 14827, 14898, 14900, 15108, 15189, 15357, 16437; Jacobs 9638; NGF 28083 (K)
Psychotria waiuensis Sohmer; 14310; NGF 25626
Psychotria sp. ?nov.; 15170, 15174A, 16593; Vinas & Kairo 304
Psychotria sp. (liane); LAE 62053
Psydrax sp., =*Canthium cymigerum* (Val.) B.L. Burtt; 14382, 14784, 14810; NGF 24475, 25667
Scyphiphora hydrophyllacea Gaertn.; 14636; NGF 45112
Timonius paiawensis S. Darwin; 14362, 14440, 14520, 14522, 15065, 15338; Conn et al. 301, 313; LAE 52328; NGF 39097, 47767
Timonius timon (Spreng.) Merr. var. *buloloensis* S. Darwin; 14362B; Jacobs 9626; NGF 44207
Timonius timon (Spreng.) Merr. var. *timon*; 15367
Timonius sp., aff. *rufescens* (Miq.) Boerl.; 14798, 14870
Timonius sp. ?nov.; 14328, 14663, 14781, 15106, 15567
Uncaria lanosa Wall. var. *appendiculata* (Benth.) Ridsd.; 14767
Urophyllum glaucescens Val., vel aff.; 14401, 14891, 15089; Jacobs 9565, 9692; LAE 52056, 52299, 52338; NGF 24448, 28094 (K), 31621 (K), 31626 (K), 45132; Rau 607, 612
Xanthophytum papuanum Wernh.; 14454, 16418; NGF 44210, 45184

RUTACEAE

Acronychia trifoliolata Zoll. & Mor.; 14901, 15118, 15148, 16419
Flindersia laevicarpa White & Francis var. *heterophylla* (Merr. & Perry) Hartley; 14519, 15124, 15132; NGF 31636
Halfordia drupifera F.v.M.; 14344
Melicope denhamii (Seem.) Hartley; 14420, 14523, 14736, 15031
Melicope xanthoxyloides (F.v.M.) Hartley; 15373
Zanthoxylum novoguineense Hartley; 14699, 14759, 14785, 14801, 14813 (distr. as *Euodia* aff. '*alata-mollis* group') 16645; LAE 52311, 52329; NGF 25690
genus indet.; 15564

SABIACEAE

Sabia pauciflora Bl.; 15431

SALICACEAE

Casearia erythrocarpa Sleumer, vel aff.; 14327, 14339, 14368, 14451, 14701, 14806, 14846, 14861, 14909, 14988, 15355; NGF 25671, 28082 (K)
Casearia cf. *macrantha* Gilg; 14848, 14916, 14939, 15162; NGF 52045

Casearia sp., aff. *flexicaulis* K. Sch.; 14357, 14545, 14605, 14616, 14829, 14959, 15115 (14357, 14616, 14829 distr. as *Glochidion* sp.); LAE 51681; NGF 25661
Casearia sp., closest to ?*novoguineensis* Val.; 15418, 16605
Homalium d'entrecasteauxense Craven; 14650, 14876
Scolopia novoguineensis Warb.; 14612, 14627
Trichadenia sasae Takeuchi; 15589, 16561

SANTALACEAE
Exocarpos latifolius R.Brown; 14889, 15120, 15372, 16423; LAE 51666; NGF 39418
Scleropyrum aurantiacum (Laut. & K. Sch.) Pilger; 15198; NGF 31629 (K), 45131, 45174

SAPINDACEAE
Alectryon ferrugineus (Bl.) Radlk.; 14728, 14802, 15247
Arytera cf. *litoralis* Bl.; 14925
Cnesmocarpon discoloroides Adema; 15092; NGF 25007
Dictyoneura obtusa Bl. ('Morobe race' oblique leaflets); 15362, 16427
Euphorianthus euneurus (Miq.) Leenh.; LAE 52318
Guioa grandifoliola Welzen; 14980; Conn et al. 195, 319 (nv); NGF 45154
Guioa rigidiuscula Radlk., or '*rigidiuscula* com plex'; 15208, 16614
Harpullia longipetala Leenh.; 15165; NGF 25679
Harpullia ramiflora Radlk.; LAE 62055 (nv)
Mischocarpus pyriformis (F.v.M.) Radlk. ssp. *papuanus* (Radlk.) Ham; NGF 47775
Pometia pinnata J.R. & G. Forst.; NGF 31639
Sarcopteryx squamosa (Roxb.) Radlk.; NGF 44208, 45099
?*Synima* aff. *cordierorum* (F.v.M.) Radlk.; 14550, 14577, 14633
genus indet.; NGF 45216 (nv; .isted as *Elattostachys* in LAE logbook)

SAPOTACEAE
Magodendron mennyae Vink; 16570; Conn et al. 194; Jacobs 9537; NGF 24436, 45146
Palaquium cf. *warburgianum* Schltr.; 15085
Pichonia sp., ?*lauterbachiana* (H.J. Lam) Pennington; 14558, 14568, 14793, 14982, 14986 (nos. distr. as *Pouteria sarcospermoides* H.J. Lam); LAE 51674; NGF 39435, 44605, 45107
Pouteria ledermannii (K. Krause) Baehni; 14471, 15088 (dets. W. Vink)
Pouteria luzoniensis (Merr.) Baehni; 14355
Pouteria maclayana (F.v.M.) Baehni; Jacobs 9573
Pouteria obovoidea H.J. Lam; NGF 24496
genus indet.; NGF 45188

SIMAROUBACEAE
Quassia indica (Gaertn.) Nooteboom; 14389

SOLANACEAE
Capsicum anuum L.; SR, cult. Lababia
Solanum anfractum Symon; Jacobs 9558; NGF 24441
Solanum melongena L.; SR, cult. Lababia
Solanum symonianum Takeuchi; 12027

STEMONURACEAE
Gomphandra ?*pseudoprasina* Sleum.; LAE 62056 (nv)
Stemonurus ammui (Kaneh.) Sleum.; 14400, 14756, 14857, 14983; NGF 24481 (nv)

SYMPLOCACEAE
Symplocos cochinchinensis (Lour.) S. Moore; 14464, 15008, 15152

THEACEAE
Gordonia papuana Kobuski; 15093, 16576; NGF 31625 (K)

THYMELAEACEAE
Phaleria coccinea (Gaud.) F.v.M.; 14745, 15017, 15193, 15218, 15565; NGF 28062 (K)
Phaleria macrocarpa (Scheff.) Boerl.; 16601

URTICACEAE
Dendrocnide longifolia (Hemsl.) Chew; 15260
Poikilospermum sp.; 14934

VERBENACEAE
Stachytarpheta cayennensis (Rich.) M.Vahl; 14537

VITACEAE
Cissus sp., '*javana-discolor* group'; Jacobs 9592
Tetrastigma sp.; NGF 28074 (K; Leiden det. ticket gives *T. pedunculare*)

WINTERACEAE
Zygogynum sp.; 14465

FAMILY INDET.; 14373, 14374, 14675

ACKNOWLEDGMENTS

The botanical surveys of the KWMA were supported by the Botanical Research Institute of Texas, Harvard University, and the John D. and Catherine T. MacArthur Foundation. I thank my associates at the Village Development Trust for their assistance with the Kamiali program, including the Hon. Sasa Zibe-Kokino (VDT co-founder and Minister of the PNG Dept. of Environment and Conservation), Aung Kumal (Executive Director), Karol Kisokau (Director of Research and Conservation), John Sengo (Manager of Integrated Conservation and Development), Bing Siga (Field Coordinator) and Madlene Kavua (Science Officer). Hitofumi Abe (Ecosystem Research Group, University of Western Australia) wrote the Japanese translation. John Pipoly (FTG) provided the Latin diagnoses. Kipiro Damas (LAE) brought the new *Trichadenia* to my attention. Parataxonomists Demas Ama and Ali Towati were my principal associates in the field. Parataxonomist Nathan (no surname), also assisted with the collecting until his recent and untimely death from acute cerebral malaria.

The following specialists provided determinations and/or shared information on their respective groups: L. Craven (noncapsular Myrtaceae), H. Fortune (Cunoniaceae), N.H.S. Howcroft (Orchidaceae), K.-L. Huynh (Pandanaceae), M. Jebb (Aristolochiaceae, Lecythidaceae), J. Kessler (Annonaceae), A. Kjaer (Arecaceae), D. Middleton (Apocynaceae), J. Pipoly (Myrsinaceae), S.S. Renner (Melastomataceae), A. Schuiteman (Orchidaceae), P.F. Stevens (Clusiaceae, Ericaceae, passim), W. Vink (Sapotaceae), E. de Vogel (Orchidaceae), and P. Wilson (capsular Myrtaceae).

email: luc.brouillet@umontreal.ca

ABSTRACT

A new combination is reported here for an infraspecific taxon in *Eurybia* from North America: ***Eurybia glauca*** (Nutt.) G.L. Nesom var. ***pulchra*** (S.F. Blake) Brouillet, comb. nov.

RESUMEN

Se realiza una nueva combinación para un taxon infraspecífico en *Eurybia* de Norte América: ***Eurybia glauca*** (Nutt.) G.L. Nesom var. ***pulchra*** (S.F. Blake) Brouillet, comb. nov.

INTRODUCTION

The North American genus *Eurybia*, segregated from *Aster* by Nesom (1994), has now been shown convincingly to be distinct from the Eurasian *Aster* s.str. (Noyes & Rieseberg 1999; Brouillet et al. 2001a, b; Bastien & Brouillet 2002; Semple et al. 2002). Nesom (1994, 1997) provided most of the combinations needed in this genus. Nevertheless, during preparation of the treatments of this genus for the Flora of North America project, differences in taxonomic concepts from those suggested by Nesom (1994) have led me to propose a new combination.

Eurybia glauca (Nutt.) G.L. Nesom

In his taxonomy of *Eurybia*, Nesom (1994) recognized *Eurybia pulchra* (S.F. Blake) G.L. Nesom as a species distinct from *Eurybia glauca* (Nutt.) G.L. Nesom, justifying it by the smaller leaves, more acute phyllaries and glandularity. Yet, except for glandularity, which does not appear to vary gradually from one taxon to the other, the other features all fit within the range encountered in *E. glauca*, apart from a slight tendency toward larger reproductive features in *E. pulchra*; leaf size ranges overlap considerably when a large sample of *E. glauca* is considered. A morphometric study would be needed to determine the exact amplitude and significance of size differences between the two taxa. The ranges of the two taxa appear to be parapatric in southern Utah-northern Arizona, with *E. pulchra* restricted to the vicinity of the Grand Canyon while *E. glauca* ranges widely to the north and east into the Southern Rocky Mountains; it must be

noted, however, that populations of the latter are found in Arizona south and east of the Grand Canyon. Nonetheless, no mixed population of the two taxa has been reported. The restricted range and distinct glandularity justify that *E. pulchra* be recognized as a taxon. Nevertheless, glandularity alone does not seem to justify recognizing *E. pulchra* as a distinct species. I agree with Nesom (1994) that the inclusion by Cronquist (1994) of *E. pulchra* within *E. wasatchensis* is misguided as it is based only on the shared possession of glands. Several characters distinguish *E. pulchra* and *E.wasatchensis*, including leaf glaucousness and phyllary habit (appressed vs squarrose), which the former shares with *E. glauca*. Therefore, I prefer to recognize the former as a variety of the latter, as is done by Welsh et al. (1987), even though it was originally described as a subspecies.

Eurybia glauca (Nutt.) G.L. Nesom var. **glauca**

Eurybia glauca (Nutt.) G.L. Nesom var. **pulchra** (S.F. Blake) Brouillet, comb. et stat. nov. BASIONYM: *Aster glaucodes* S.F. Blake subsp. *pulcher* S.F. Blake, Proc. Biol. Soc. Washington 35:174. 1922. *Eurybia pulchra* (S.F. Blake) G.L. Nesom, Phytologia 77:261. 1994.

The combination *Aster glaucodes* Blake var. *pulcher* (Blake) Kearney & Peebles, reported in Welsh et al. (1987), is not valid because Kearney and Peebles (1960) did not make a formal status change with proper reference to the basionym. The name was thus never validly published at the varietal rank. These author perhaps unwittingly referred to the infraspecific taxon as a variety instead of a subspecies and might not have intended to make a new combination.

The origin of glandularity in *E. glauca* var. *pulchra* and *E. wasatchensis*, as compared to the eglandular *E. glauca* var. *glauca*, could be explained by considering the other members of section *Herrickia*, to which these taxa clearly belong: *Eurybia horrida* (Wooton & Standl.) G.L. Nesom (formerly *Herrickia horrida*) and *Aster kingii* (Brouillet et al. 2001a, b). All members of section *Herrickia* are glandular except *E. glauca* var. *glauca*. It is more parsimonious to explain the lack of glands in the latter by a loss of glands after speciation. This hypothesis would imply that the presence of glands in var. *pulchra* is ancestral within the species, and that var. *glauca* may represent a relatively more recent expansion of an eglandular phenotype to the range of the species as known today, from a more restricted original area perhaps close to the San Juan river basin where var. *pulchra* is restricted today.

ACKNOWLEDGMENTS

I would like to thank Guy L. Nesom (Botanical Research Institute of Texas) and Kanchi Gandhi (Harvard University Herbaria) for their useful comments on the manuscript. This project was supported in part by a research grant from NSERC (Canada).

Hawthorns (*Crataegus*) and medlars (*Mespilus*) are in the rose family (Rosaceae). This 180 page book is beautifully illustrated and adorned with excellent color photos from a variety of sources. The author brings together in one place a broad mix of information on these two groups of closely related plants. "There are perhaps 140 species of *Crataegus* in the world"; chapter seven of the book covers "69 wild and hybridogenous species and their more commonly available cultivars." Chapters include **1)** Hawthorns and Medlars in Folklore; **2)** Natural History and Conservation, Structure and Reproductive Biology; **3)** Practical Value; **4)** Cultivation; **5)** Breeding and Selection; **6)** Classification and Identification; **7)** Hawthors; and **8)** Medlars and Intergeneric Hybrids. There are four appendices: **1)** Preparation of Herbarium specimens; **2)** Checklist of *Crataegus* and *Mespilus* Species; **3)** Tabular Key to Hawthorns and Medlars; and **4)** Conversion Charts. A Glossary, Bibliography, and Index complete the book.—*Barney Lipscomb, Botanical Research Institute of Texas, 509 Pecan St, Fort Worth, TX 76102-4060, U.S.A., barney@brit.org.*

Contents.—Foreword, Preface, Acknowledgments, **1)** Introduction, **2)** Learning to Identify Native Palms (Identification Key for the Palms), **3)** Palms with Peculiar Distributions, **4)** Palms of the Lesser Antilles, Glossary, Nomenclatural Notes on the Palms, Making Sense of Common Names, Palm Species and Their Synonyms, Known Introduced Palms, Photograph Data, References, and Index.

"Each species account includes, the local name(s), the geographical distribution and density (distribution map shows each species' geographical range), a botanical description, highlighting distinguishing features, comparisons with other similar palms, habitat preference, pollinators and distributors, economic uses and conservation statues." Twenty-two species of palms are recognized, discussed in detail and photographed in their natural habitat.

A NEW SPECIES OF *BRAZORIA* (LAMIACEAE) FROM THE CENTRAL MINERAL REGION OF TEXAS

Matt W. Turner

Univ. of Texas at Austin
McCombs School of Business
1 University Station
Austin, TX 78712, U.S.A.

ABSTRACT

Brazoria enquistii M.W. Turner sp. nov. from the central mineral region of Texas (Mason, Llano and Burnet counties) is described. It is similar to *B. truncata* (Benth.) Engelm. & A. Gray from which it differs in having longer floral bracts with more pronounced ciliation, shorter internodes, and distinctions in the lobes of the calyx. Its habitat and edaphic preferences, unique to the genus, are also discussed. Descriptions, photographs, dot-maps, and keys to species are presented.

RESUMEN

Se describe *Brazoria enquistii* M.W. Turner sp. nov. de la región mineral central de Texas (condados de Mason, Llano y Burnet). Se asemeja a *B. truncata* (Benth.) Engelm. & A. Gray de la que se distingue por tener las brácteas florales más largas con ciliación más destacada, los entrenudos más cortos, y unas distinciones en los lóbulos del cáliz. Su hábitat y preferencias edáficas, únicos en el género, también se discuten. Se ofrecen descripciones, fotos, mapas de distribución, y clave de especies.

As noted previously in my overview of the genus (Turner 1996), the only three collections of *Brazoria* that were known to me from the central mineral region of Texas prior to 1996 (from collections housed at BRIT, GH, K, LL, OKL, TAES, TEX) possibly constituted an undescribed taxon, but lack of extant populations precluded their recognition. Subsequently, sightings of populations of the taxon by Marshall Enquist in this region prompted three years of additional fieldwork by myself. These studies have convinced me that the plant is undescribed and is deserving of specific recognition.

TAXONOMY

Brazoria enquistii M.W. Turner, sp. nov. (**Figs. 1, 2** & **3**). TYPE: U.S.A. TEXAS: Mason Co.: ca. 11 airline mi ESE of Mason, off Lower Willow Creek Rd at crossing of Willow Creek, 4 mi E of US Hwy 87, 11 May 1996, *M.W. Turner 64* (HOLOTYPE: TEX; ISOTYPES: BRIT, GH, MO, TAES, US).

Brazoriae truncatae (Benth.) Engelm. & A. Gray var. *truncatae* similis sed racemis compactissimis cum internodis 2.5–4.0 m; bracteis floralibus 8–12 mm, cum ciliis 2 - 3 mm; lobis inferioribus calycum leniter apiculatis, plerumque habentibus unum "dentem" per lobum. Plantae indescriptae conservandae sunt.

Erect annual herbs mostly 15–40 cm high, simple, or branched at base; if latter, branches immediately ascending from base. **Stems** square, pubescent below

inflorescence on all sides. **Leaves** opposite; lower leaves, if persistent, usually oblanceolate (occasionally spatulate), 5–9 cm long, 1–2 cm wide, often tapering to a long-winged petiole; margins undulate to denticulate; upper leaves oblong to elliptic, denticulate, usually sessile and partly clasping. Mature **spikes** racemoid, densely flowered, with lower internodes mostly 2.5–4.0 mm long; flowers decussate. **Bracts** at base of pedicels mostly ovate-orbicular, 8–12 mm long; margins ciliate, with hairs mostly 2–3 mm in length. **Calyces** broadly campanulate, 5–8(–10) mm long, bilabiate; the two lower lobes mostly truncate with one "tooth," woolly-tomentose at base, with many eglandular hairs reaching 2 mm in length; upper middle lobe usually truncate or shallowly mucronate; upper lateral lobes mucronate to apiculate; capitate-glandular hairs scattered over both lower and upper lobes. **Corollas** 15–25 mm long, bilabiate, pale lavender and usually distinctly veined, sparsely puberulent along the upper surface; upper lip bifid; lower lip trifid, lobes usually emarginate; throats with annulus usually perpendicular to axis of corolla 2–3 mm above ovary, maculate, with distinct hump on lower surface beneath stamens. **Stamens** 4, fertile, the anterior pair longer than the posterior. **Filaments** ca. 1 mm wide at base of free portion, conspicuously winged, villous, arched inward near apices; upper pair free from adnation to corolla for 3–4 mm; lower, innermost pair free for 1.0–1.5 mm, with mutually opposing "bulges" or "shoulders" that, together with overlapping hairs, hold style in epipetalous position. **Thecae** apiculate laterally at base, dark purple and ringed with white; upper pair slightly smaller than lower (ca. 1.2 mm vs 2.0 mm); ventral (rarely dorsal) surface of connective tissue between thecae usually with several to many white hairs. **Styles** 1.0–1.5 mm long, bilobed, glabrous; branches linear-lanceolate. **Nutlets** mostly 1.5–2.5(–3.5) mm long, strongly trigonal, with incurved hispidulous hairs, rarely glabrous.

Distribution.—The most geographically isolated species of the genus, *Brazoria enquistii* is known only from three counties—Burnet, Llano, and Mason (**Fig. 1**)—and I have only been able to locate extant populations in the latter two of these. Many attempts to ascertain distribution extensions (beyond what is reported here) have been made in the surrounding vicinity over the past five years to no avail. Although only ca. 130 km separates the taxon (Llano/Burnet Co. border area) from the nearest populations of *B. truncata* (Bastrop Co.) (**Fig. 2**), the intervening distance presents the sand-loving genus with a barrier of limestone, the central mineral region being renowned as a granitic outcrop (which weathers to sand) surrounded by calcareous soils. This geographic isolation, together with its infrequent occurrence and short blooming period, have kept the taxon in relative obscurity.

Habitat.—*Brazoria enquistii*, unlike the eastern species of the genus which tend to prefer the loose white sands of xeric slopes, grows almost exclusively along granitic streambeds of the Llano River watershed. Only four of the 16 populations discovered by the author (sites of *Turner 71, 72, 95* and *96*) are not

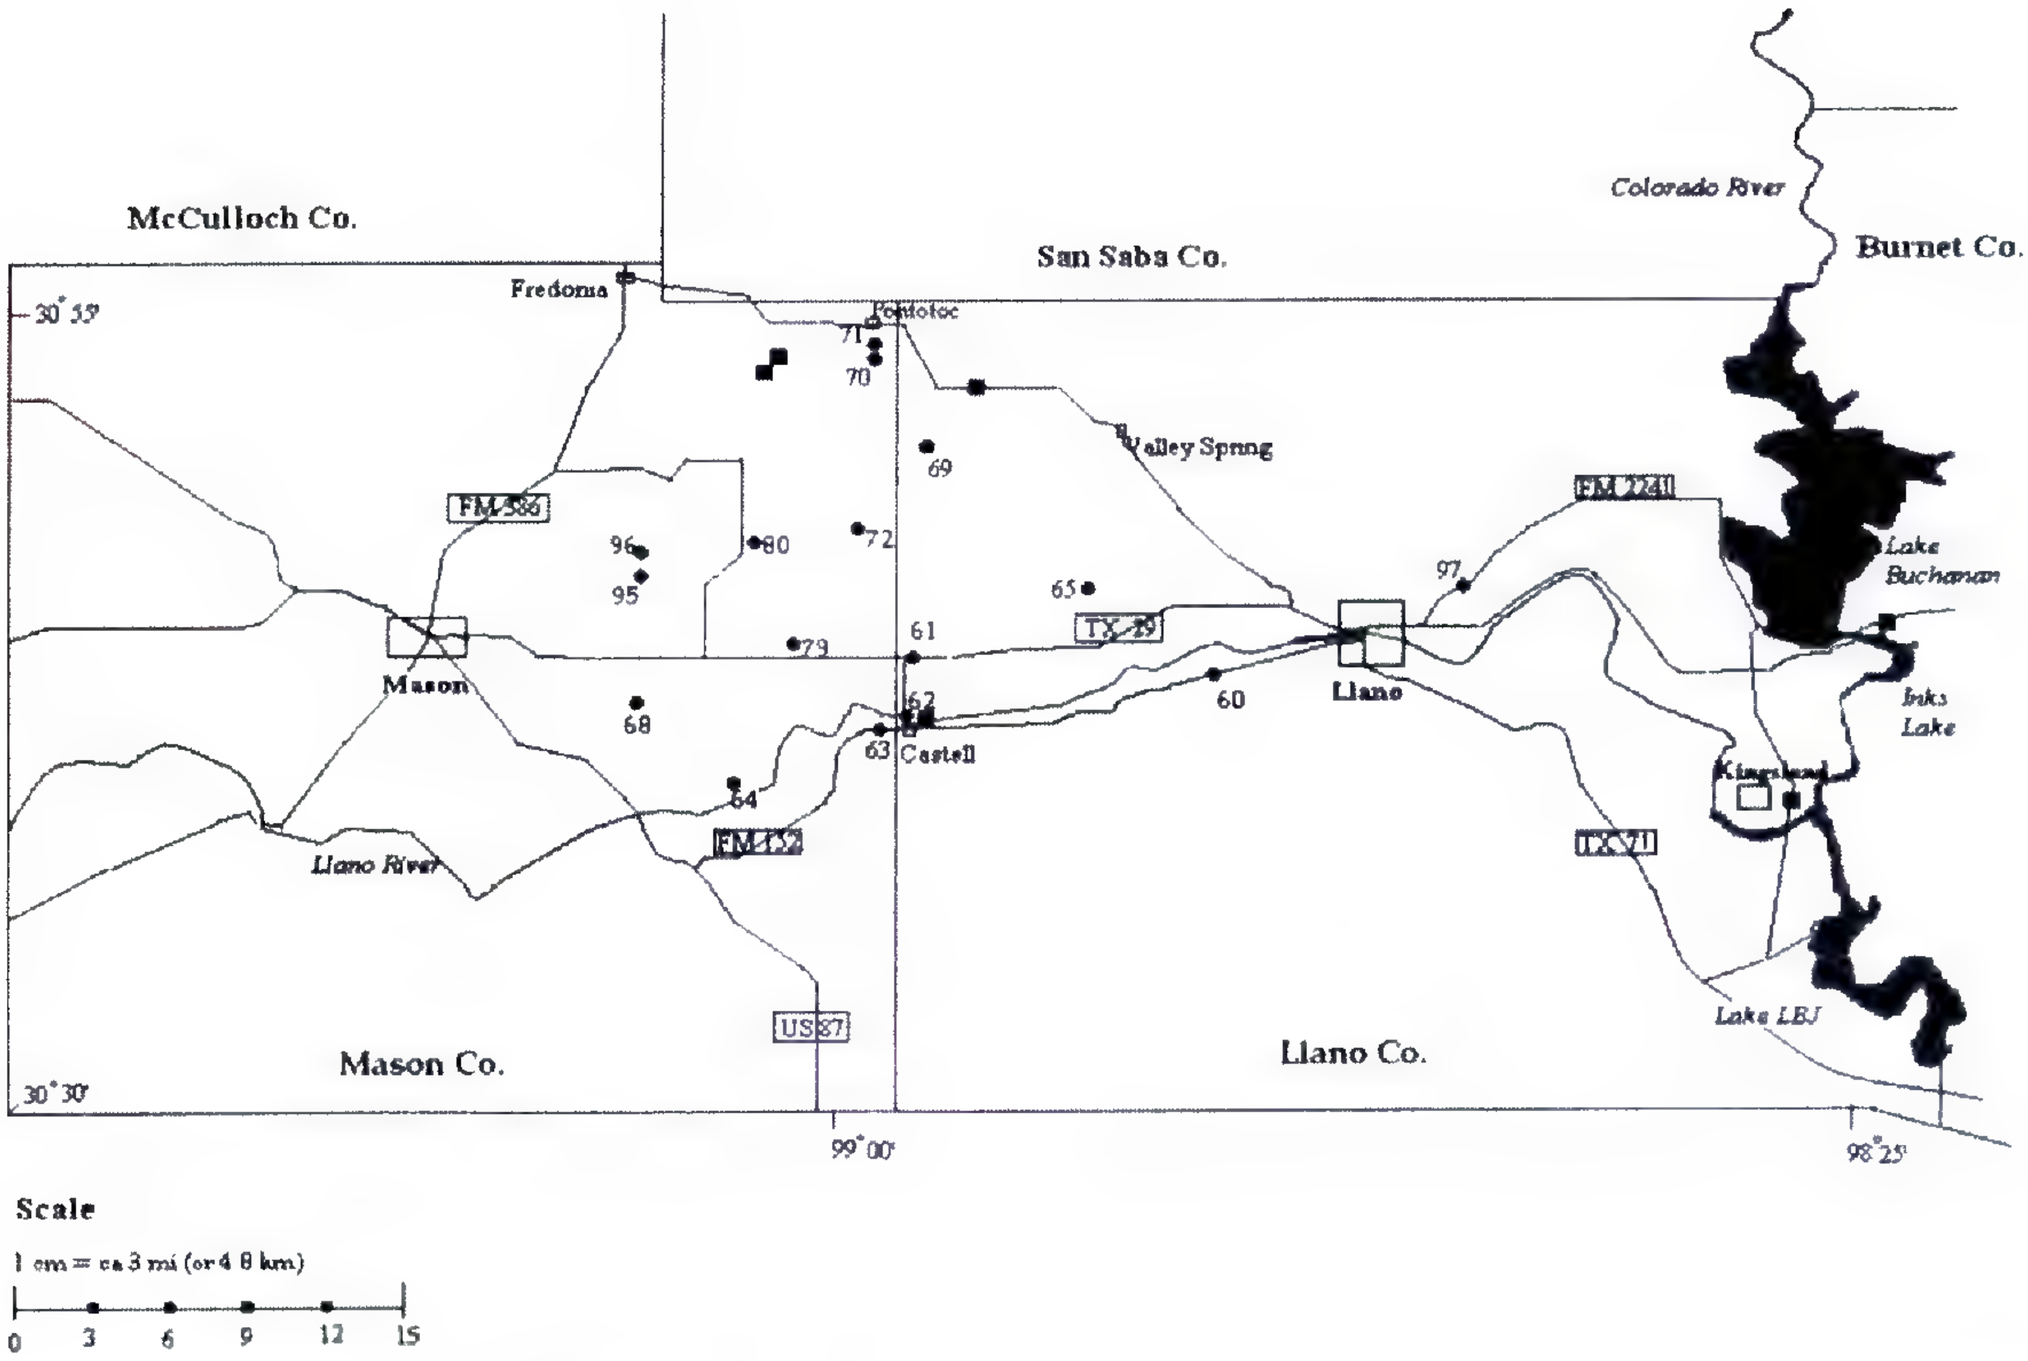

FIG. 1. Documented distribution of *Brazoria enquistii* in three counties of central Texas. Closed circles represent specimens collected by author; numbers refer to collection numbers cited. Closed squares represent other documented collections known to date and cited herein.

along such streambeds (but even two of these are within 100 m of one). More specifically, the species is rarely found near the water's edge, but rather occurs on the raised, sparsely-vegetated sand embankments within 10–20 m of adjacent streams. The species seems to prefer embankments along permanent water, and is only rarely found in dry washes and gullies. One of the largest populations (estimated at 10,000+ individuals at the type locality) was discovered on a large, flat, sand island in the middle of Willow Creek as it approaches the Llano River. Indeed, the species seems to flourish in creek beds as they widen downstream near their mouths (presumably because the waterways accumulate more sand), and becomes less abundant upstream as the creeks become narrower. Only three of the 22 sites known to date (both historical and extant) lie south of the Llano River.

Phenology.—All known collections are from the month of May.

Remarks.—*Brazoria enquistii* most closely resembles *B. truncata* var. *truncata*. The most obvious distinguishing character of the taxon is its long and well-developed bracts (see Fig. 3 and key following), which almost conceal the developing buds, in stark contrast to the shorter bracts of *B. truncata* whose buds, left exposed to view, display themselves in the compact rows that have earned that species the common name of "rattlesnake flower." Another obvious character is the internode length which is the smallest of the genus (2–4

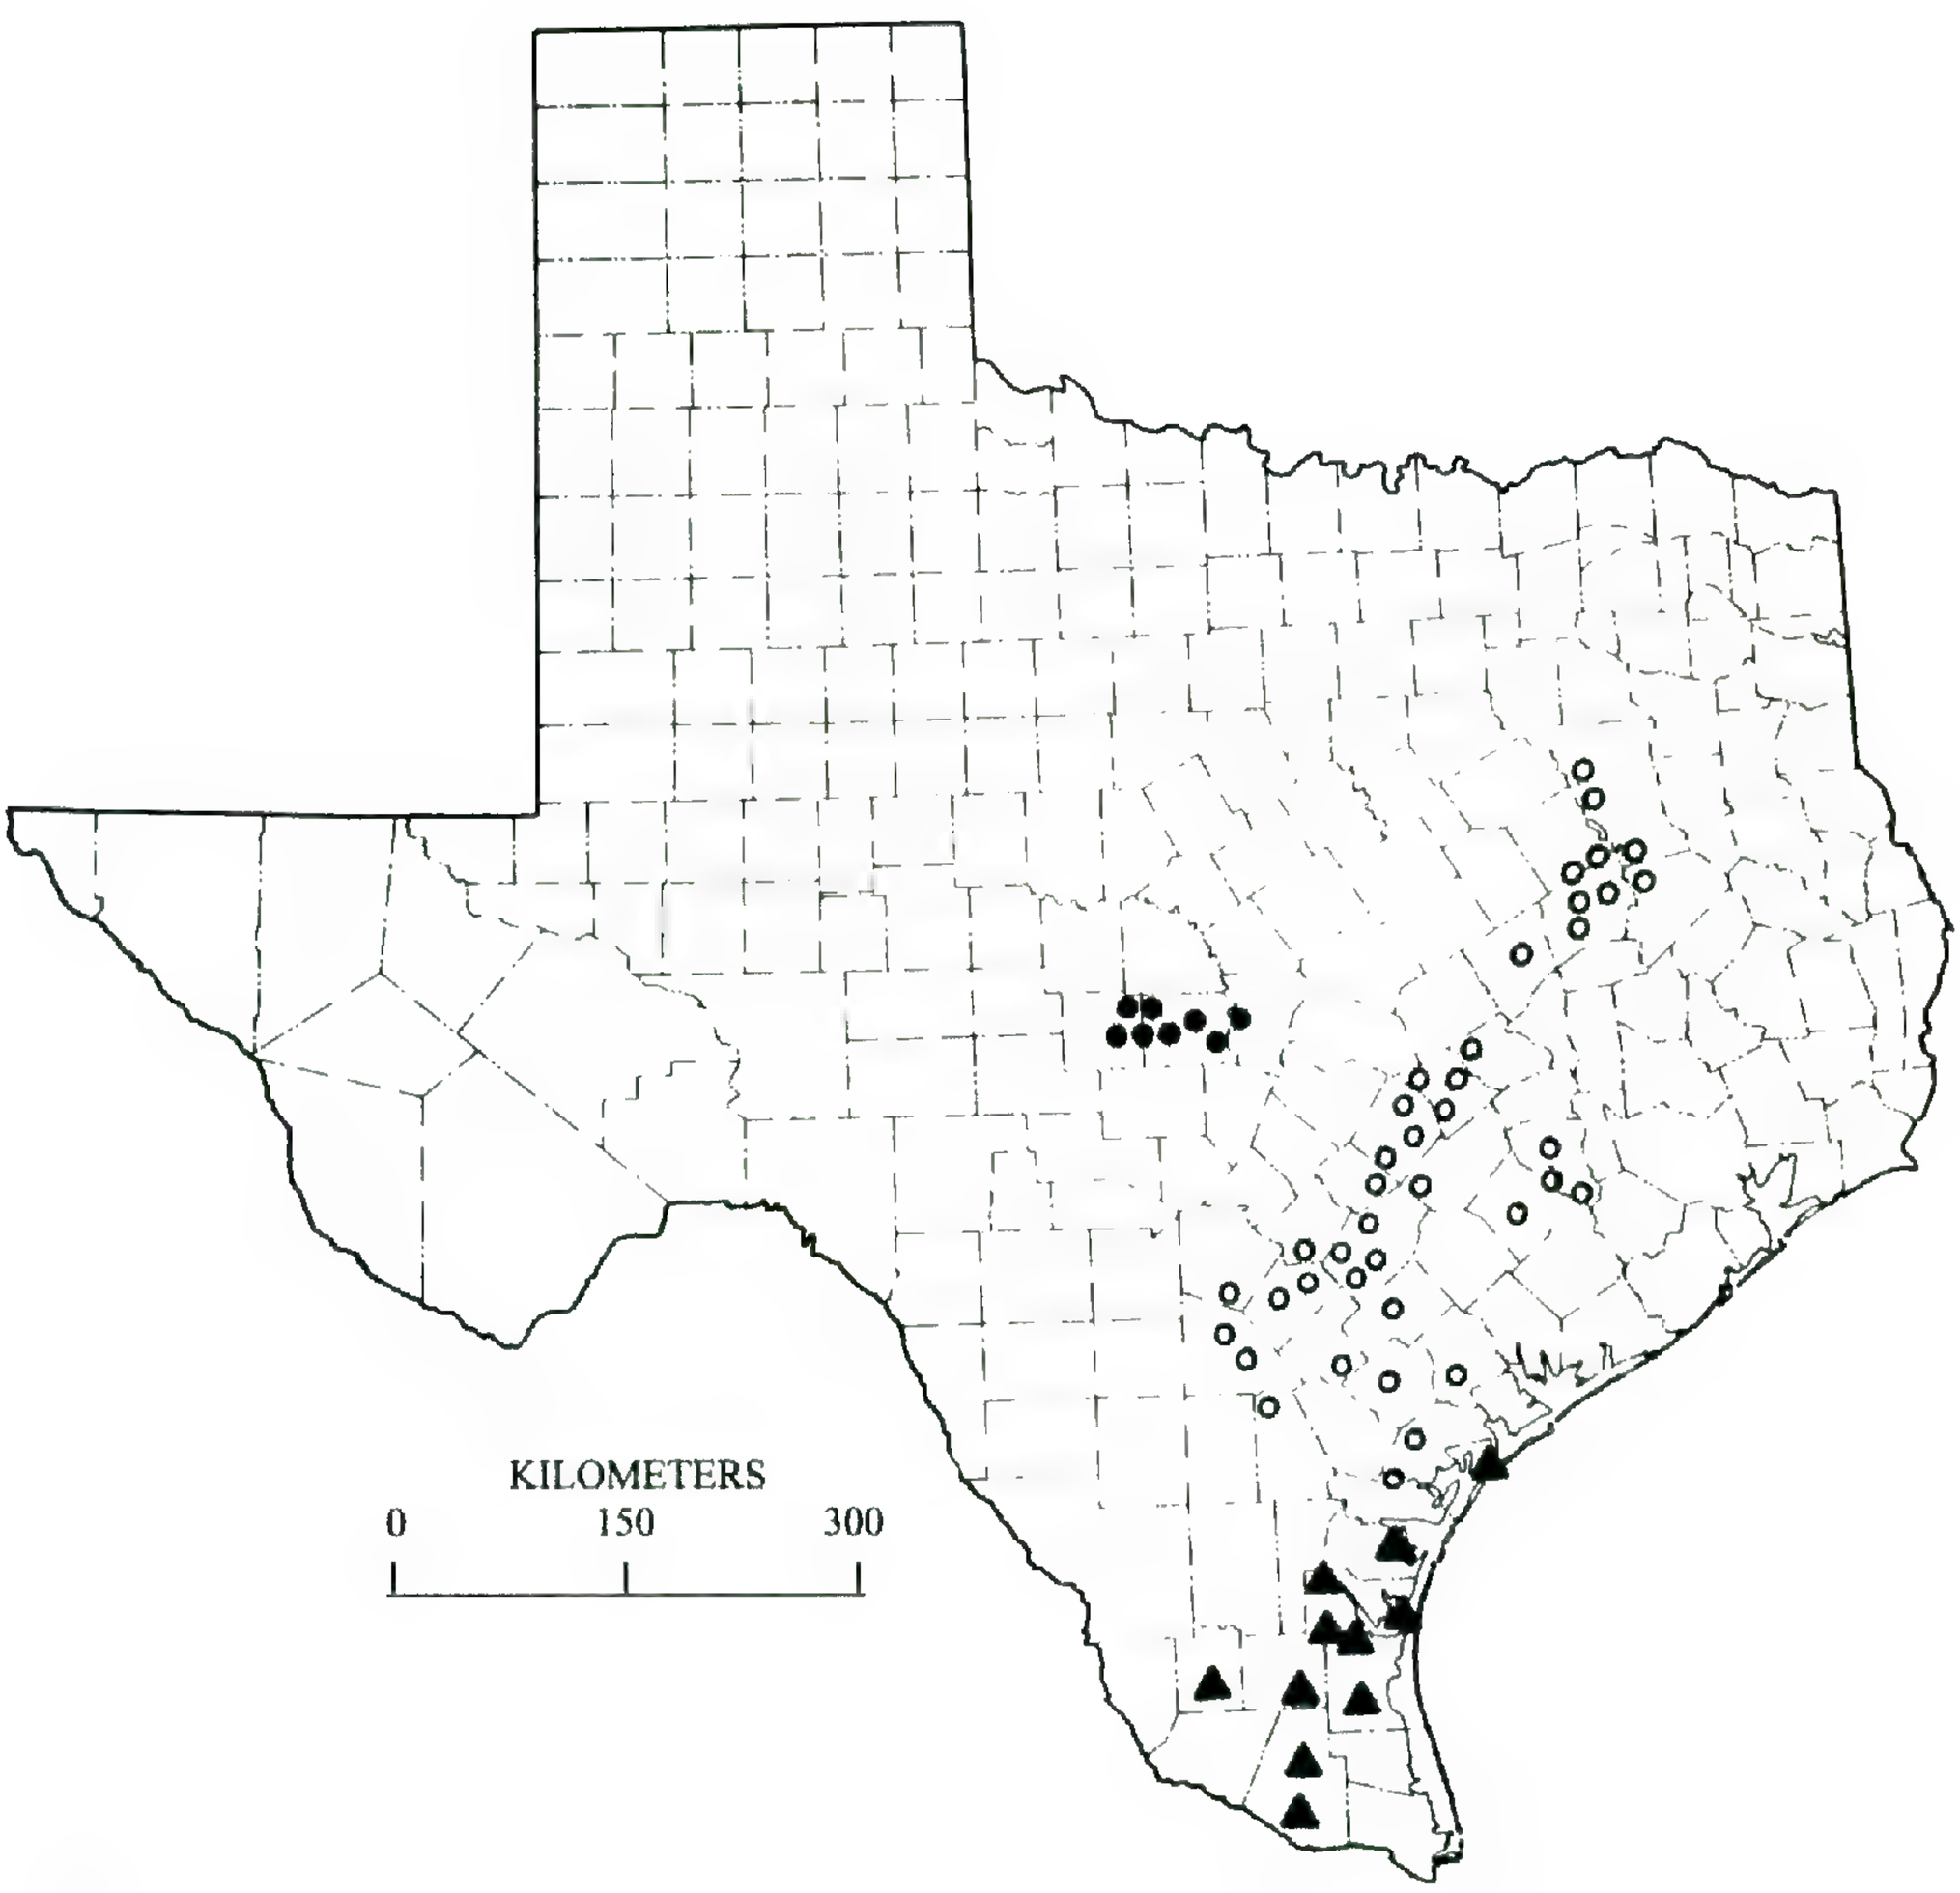

Fig. 2. Distribution of *Brazoria* species (varieties not shown). *B. arenaria* (closed triangles); *B. truncata* (open circles); *B. enquistii* (closed circles).

mm vs. 5–6 mm for *B. truncata* var. *truncata*, 8–13 mm for *B. t.* var. *pulcherrima* (Lundell) M.W. Turner, and 8–20(–30) for *B. arenaria* Lundell) and provides for an extremely compact spike.

Less obvious characters distinguishing the taxon from *B. truncata* include a longer bract ciliation (2–3 mm vs. 1–2 mm), a distinct shape to the lower lobes of the calyx (truncate or with only 1 "tooth" vs. with 3–5 "teeth"), and a subtle difference in the shape of the upper middle lobe of the calyx (truncate to shallowly mucronate vs. mucronate to apiculate).

So far as known, the first recorded collection of the taxon was made in 1910 in Kingsland (Llano Co.), *Hastings s.n.* (LL). Some 20 years later, the second recorded collection is from an area six miles northwest of Valley Spring in Llano Co., *Bauman's* [sic] *6286* (TAES). Some 30 years elapsed before the third collection was made (in 1962 in Inks Lake State Park, Burnet Co., along Clear Creek,

FIG. 3. Three comparative stages of inflorescence development in two species of *Brazoria*. Top row, **A–C:** *Brazoria enquistii*. **A,** budding inflorescence with long floral bracts (lower bracts here at the upper limit of bract range, ca. 12 mm); **B,** early stages of flowering, bracts subtending the buds; **C,** mature flower with tightly compressed calyces due to short internodes. Bottom row, **D–F:** *Brazoria truncata* var. *truncata*. **D,** short floral bracts hidden (cf. "rattlesnake flower," the common name for this species); **E,** bracts do not (or rarely) subtend buds; **F,** internodes longer, calyces not compressed.

Correll & Ogden 25300 (LL)). An extant population has been found at a location approximating the second collection (*Turner 69*); however, the author's repeated attempts at locating living populations in the Kingsland area and in western Burnet Co. have been unsuccessful. The Kingsland area may have become overdeveloped and/or the damming of the Colorado River for Lake LBJ (in 1951 with the Alvin Wirtz Dam) may have influenced the habitat. Repeated visits to Inks Lake State Park, with special attention to Clear Creek and Spring Creek, have likewise revealed nothing. A 1996 sighting by Marshall Enquist from the Llano/Burnet Co. line area (near Buchanan Dam), prompted this investigation, but local roadwork, immediately thereafter, completely altered the site and no further sightings have been made in the area to date. At the present, the western edge of Burnet Co. represents the eastern limit for the species.

Brazoria enquistii is the most geographically restricted taxon of the genus, distributed primarily within just two counties. Like *B. truncata* var. *pulcherrima*, which is restricted to about five counties in northeastern Texas (Turner 1996), *B. enquistii* can be locally abundant, which would likely preclude it from endangered species status. On the other hand, it is more infrequent in occurrence, tending to appear in isolated patches (due to its specialized habitat), rather than being loosely scattered along the roadside. The number of individuals at a given location can vary sharply from year to year: the type locality mentioned above contained over 10,000 plants in 1996, but only about 1% of that number in 1999.

Choice of rank.—The taxon is here treated at specific rank for the following reasons: it exhibits several distinguishing morphological characters (outlined above); it has a habitat and edaphic preference distinct from the other taxa of the genus (raised embankments of streambeds in purely granitic sand vs. xeric slopes of loose, white, non-granitic sands in open woodlands and stabilized dunes); it is geographically and edaphically isolated by the surrounding calcareous soil, which erects a barrier to gene exchange; and no populations intermediate to its related taxa have been discovered.

Etymology.—The species is named for Marshall Enquist, an attorney in the Austin area, who called to my attention extant populations in the central mineral region, without which this paper would not have been possible. Mr. Enquist's excellent floristic guide (Enquist 1987), as well as his active research on native Texas flora (including *Anemone*, *Crataegus*, *Desmodium*, and *Prunus*), have been an inspiration to botanists and naturalists alike.

Specimens examined: **U.S.A. Texas. A REVISED KEY TO THE SPECIES OF *BRAZORIA*

1. Floral bracts ciliolate, with hairs 0.1–0.2 mm in length; mature plants often basally branched with branches recumbant at base; basal leaves usually persistent, oblanceolate to spatulate; southern Texas ____ **B. arenaria**
1. Floral bracts ciliate, with hairs 1–3 mm in length; mature plants often not basally branched, or, if so, with branches immediately ascending from base; basal leaves rarely persistent, usually oblong to oblong-oblanceolate; central, and southcentral to northeastern Texas.
   2. Floral bracts at base of pedicels mostly 8 12 mm in length; mature spikes very densely flowered, with lower internodes mostly 2.5–4.0 mm long; lower lobes of calyces shallowly apiculate with mostly one "tooth" per lobe; central mineral region (Burnet, Llano, Mason Co.) ____ **B. enquistii**
   2. Floral bracts at base of pedicels mostly 4–8(–9) mm in length; mature spikes less densely flowered, with lower internodes mostly 5–13 mm long; lower lobes of calyces dentate with mostly 3–5 "teeth" per lobe; not in central mineral region ____ **B. truncata**

ACKNOWLEDGMENTS

I am grateful to the Directors and Curators of the following institutions for the loan of approximately 450 herbarium specimens: BRIT, GH, K, LL, OKL, TAES, TEX. I would also like to thank Gayle Turner for assistance with the Latin diagnosis, David Hillis for bringing to my attention additional locations of *B. enquistii* near his ranch, and Tom Wendt and Lindsay Woodruff for the use of the Plant Resources Center (TEX-LL) and for the steadfast care and kindness that they have extended to me in answering my many questions.

Contents.—Abstract/Resumen, Introduction, History of Classification of *Solanum*, Nomenclatural and Taxonomic History of Section *Geminata*, Morphology, Ecology and Natural History, Species Groups and Species Concepts, Taxonomic Treatment, Doubtful Names, Excluded Names, Acknowledgments, Literature Cited, Numerical List of Taxa, Exsiccatae, Index to Scientific Names, and Appendices.

"The 126 species plus four insufficiently known taxa are discussed in context with their putative relationships." Each taxonomic entry includes nomenclature, synonyms, description, chromosome number (if known), illustration (line drawing/b/w photo), distribution (map included), selected specimens examined, local names (if applicable) and general comments on relationships to other taxa, morphology and natural history. This is a major accomplishment for the *Flora Neotropica* series

TWO NEW SPECIES OF *LIATRIS* SERIES *GRAMINIFOLIAE* (ASTERACEAE: EUPATORIEAE) FROM THE SOUTHEASTERN UNITED STATES

Robert Kral and Guy L. Nesom

Botanical Research Institute of Texas
509 Pecan Street
Fort Worth, TX 76102-4060, U.S.A.

ABSTRACT

Two species of *Liatris* series *Graminifoliae* are described for the first time and illustrations and distribution maps are provided for both. **Liatris savannensis** Kral & Nesom, sp. nov., is similar to *L. graminifolia* but differs in its larger heads with more numerous florets and broader, erose-lacerate phyllary margins. It occurs on the western coast of peninsular Florida, south of the known range of *L. graminifolia*. **Liatris patens** Nesom & Kral, sp. nov., is similar to *L. gracilis* in its consistently pedunculate heads and hirtellous-strigose stems and peduncles but differs in longer peduncles and larger heads with more numerous florets; it is similar to *L. graminifolia* in head size and number of florets but differs in its hairy stems and peduncles and longer peduncles. *Liatris patens* occurs in southeastern Georgia and adjacent South Carolina, where it apparently is allopatric in range with its close relatives *L. graminifolia* and *L. gracilis*.

RESUMEN

Se describen por primera vez dos especies de *Liatris* serie *Graminifoliae* y se aportan ilustraciones y mapas de distribución para ambas. **Liatris savannensis** Kral & Nesom, sp. nov., es similar a *L. graminifolia* pero se diferencia por sus cabezuelas más grandes con flósculos más numerosos y márgenes de los filarios más anchos y lacerados. Aparece en la costa oeste de la península de Florida, al sur del área conocida de *L. graminifolia*. **Liatris patens** Nesom & Kral, sp. nov., es similar a *L. gracilis* por sus cabezuelas pedunculadas, y tallos y pedúnculos hirto-estrigosos pero se diferencia por tener pedúnculos más largos y cabezuelas más grandes con muchos más flósculos; es similar a *L. graminifolia* por el tamaño de las cabezuelas y número de flósculos pero se diferencia por sus tallos pelosos, y pedúnculos pelosos y más largos. *Liatris patens* aparece en el sureste de Georgia y parte adyacente de Carolina del Sur, donde aparentemente es alopátrica con sus parientes cercanos *L. graminifolia* y *L. gracilis*.

The species of *Liatris* series *Graminifoliae* (Gaiser 1946) are characterized by a pappus of barbellate bristles, corolla tubes pilose within, phyllaries nearly flat to rounded, obtuse, or acute at the apex, and sessile or pedunculate heads with 3–17(–20) florets. Gaiser recognized five species in series *Graminifoliae*: *L. graminifolia* Willd., *L. helleri* Porter, *L. gracilis* Pursh, *L. regimontis* (Small) K. Schum., and *L. turgida* Gaiser. Stucky (1991, 1992) and Stucky and Pyne (1990) recently clarified concepts related to several related taxa, reviving use of the name *L. virgata* Nutt. (to include *L. regimontis* and *L. graminifolia* var. *smallii* (Britt.) Fern. & Grisc.), and adding *L. cokeri* Pyne & Stucky to the group. *Liatris gholsonii* L. Anderson, an endemic of the Apalachicola River bluff system in

SIDA 20(4): 1573–1583. 2003

the Florida panhandle and close relative of *L. gracilis*, was recently described (Anderson 2002). The present study adds two more species to this group—the first endemic to a small region on the western coast of peninsular Florida, the second known from a broader area of southeastern Georgia.

In the fall of 1964, during a field study of slash pine-sabal palmetto savanna adjacent to brackish marshland in the vicinity of Punta Gorda, Florida, the first author collected an unusual *Liatris*. Additional collections were made from other sites in two adjacent counties over the course of the next 15 years, but a final determination of its identity was not made and other work intervened. After 40 years, its description is presented here.

Liatris savannensis Kral & Nesom, sp. nov. (**Fig. 1, 3**). TYPE: UNITED STATES. FLORIDA. Charlotte Co.: wet pine/cabbage palm flats, ca. 3 mi S of Punta Gorda, 7 Oct 1979, *R. Kral 64559* (HOLOTYPE: US; ISOTYPES: FSU, NY, VDB, VSC).

Liatri graminifoliae similis, sed capitulis majoribus flosculis numerosioribus et phyllariis marginibus latioribus erosi-laceratis differt; *L. spicatae* similis sed differt caulibus glandulosis, foliis manifeste punctatis marginibus ciliatis, et tubis corollarum interne pilosis.

Plants perennials, corms ranging from globose to irregularly cylindric, narrowly ovoid, or fusiform and caudex-like. Stems stiffly erect, (80–)90–130 cm tall, simple or (rarely) ascending-branched, terete, irregularly multicostate and shallowly grooved, glabrous but (including inflorescence axis) often sparsely but evidently sessile-glandular. Leaves in high spiral, the oldest approximate, mostly broken away by anthesis, but, if present, elongate (–30 cm), essentially narrowly linear-lorate, those immediately above on stout internodes to 5 cm or more, pandurate, gladiate-lorate, (17–)20–40 cm long, with broad, clasping-based, intermittently pilose-ciliate petiole bases, gradually narrowed, then dilating to linear-elliptic, linear-spatulate or linear oblanceolate blades 3–10 mm wide, the petiolar nerves convergent to few laterals (ultimately no laterals), the median nerve broad, sulcate or compound, apex variously acute, callused, margin entire, slightly thickened, surfaces pale green with darker glandular punctation, glabrous except for some intermittent pilosity along abaxial midrib; upstem leaves gradually shortening, narrowing in tighter spiral, sessile, mostly ascending, proximally pilose-ciliate, transitional to inflorescence bracts, the lowermost exceeding, the uppermost exceeded by, heads. Inflorescence mostly determinate, spiciform, rarely branched, its axis typically at least as long as the leafy part of the plant, the heads sessile or on peduncles mostly 1–2 mm long. Heads spreading-ascending, turbinate-campanulate; involucre just past anthesis (7–)8–10 mm high from base to involucral apex, (8–)9–11(–12) mm wide (pressed); phyllaries ciliate, in (3–)4(–5) series, the lowermost shortest, 1.5–3 mm, ovate to oblong, fleshiest, greenish, glandular-punctate, 3-nerved, progressively longer inward, 4–6 mm, becoming obovate, then spatulate 7–9(–10) mm, apically broadly rounded, with a hyaline, pinkish-purple, erose to lacerate bor-

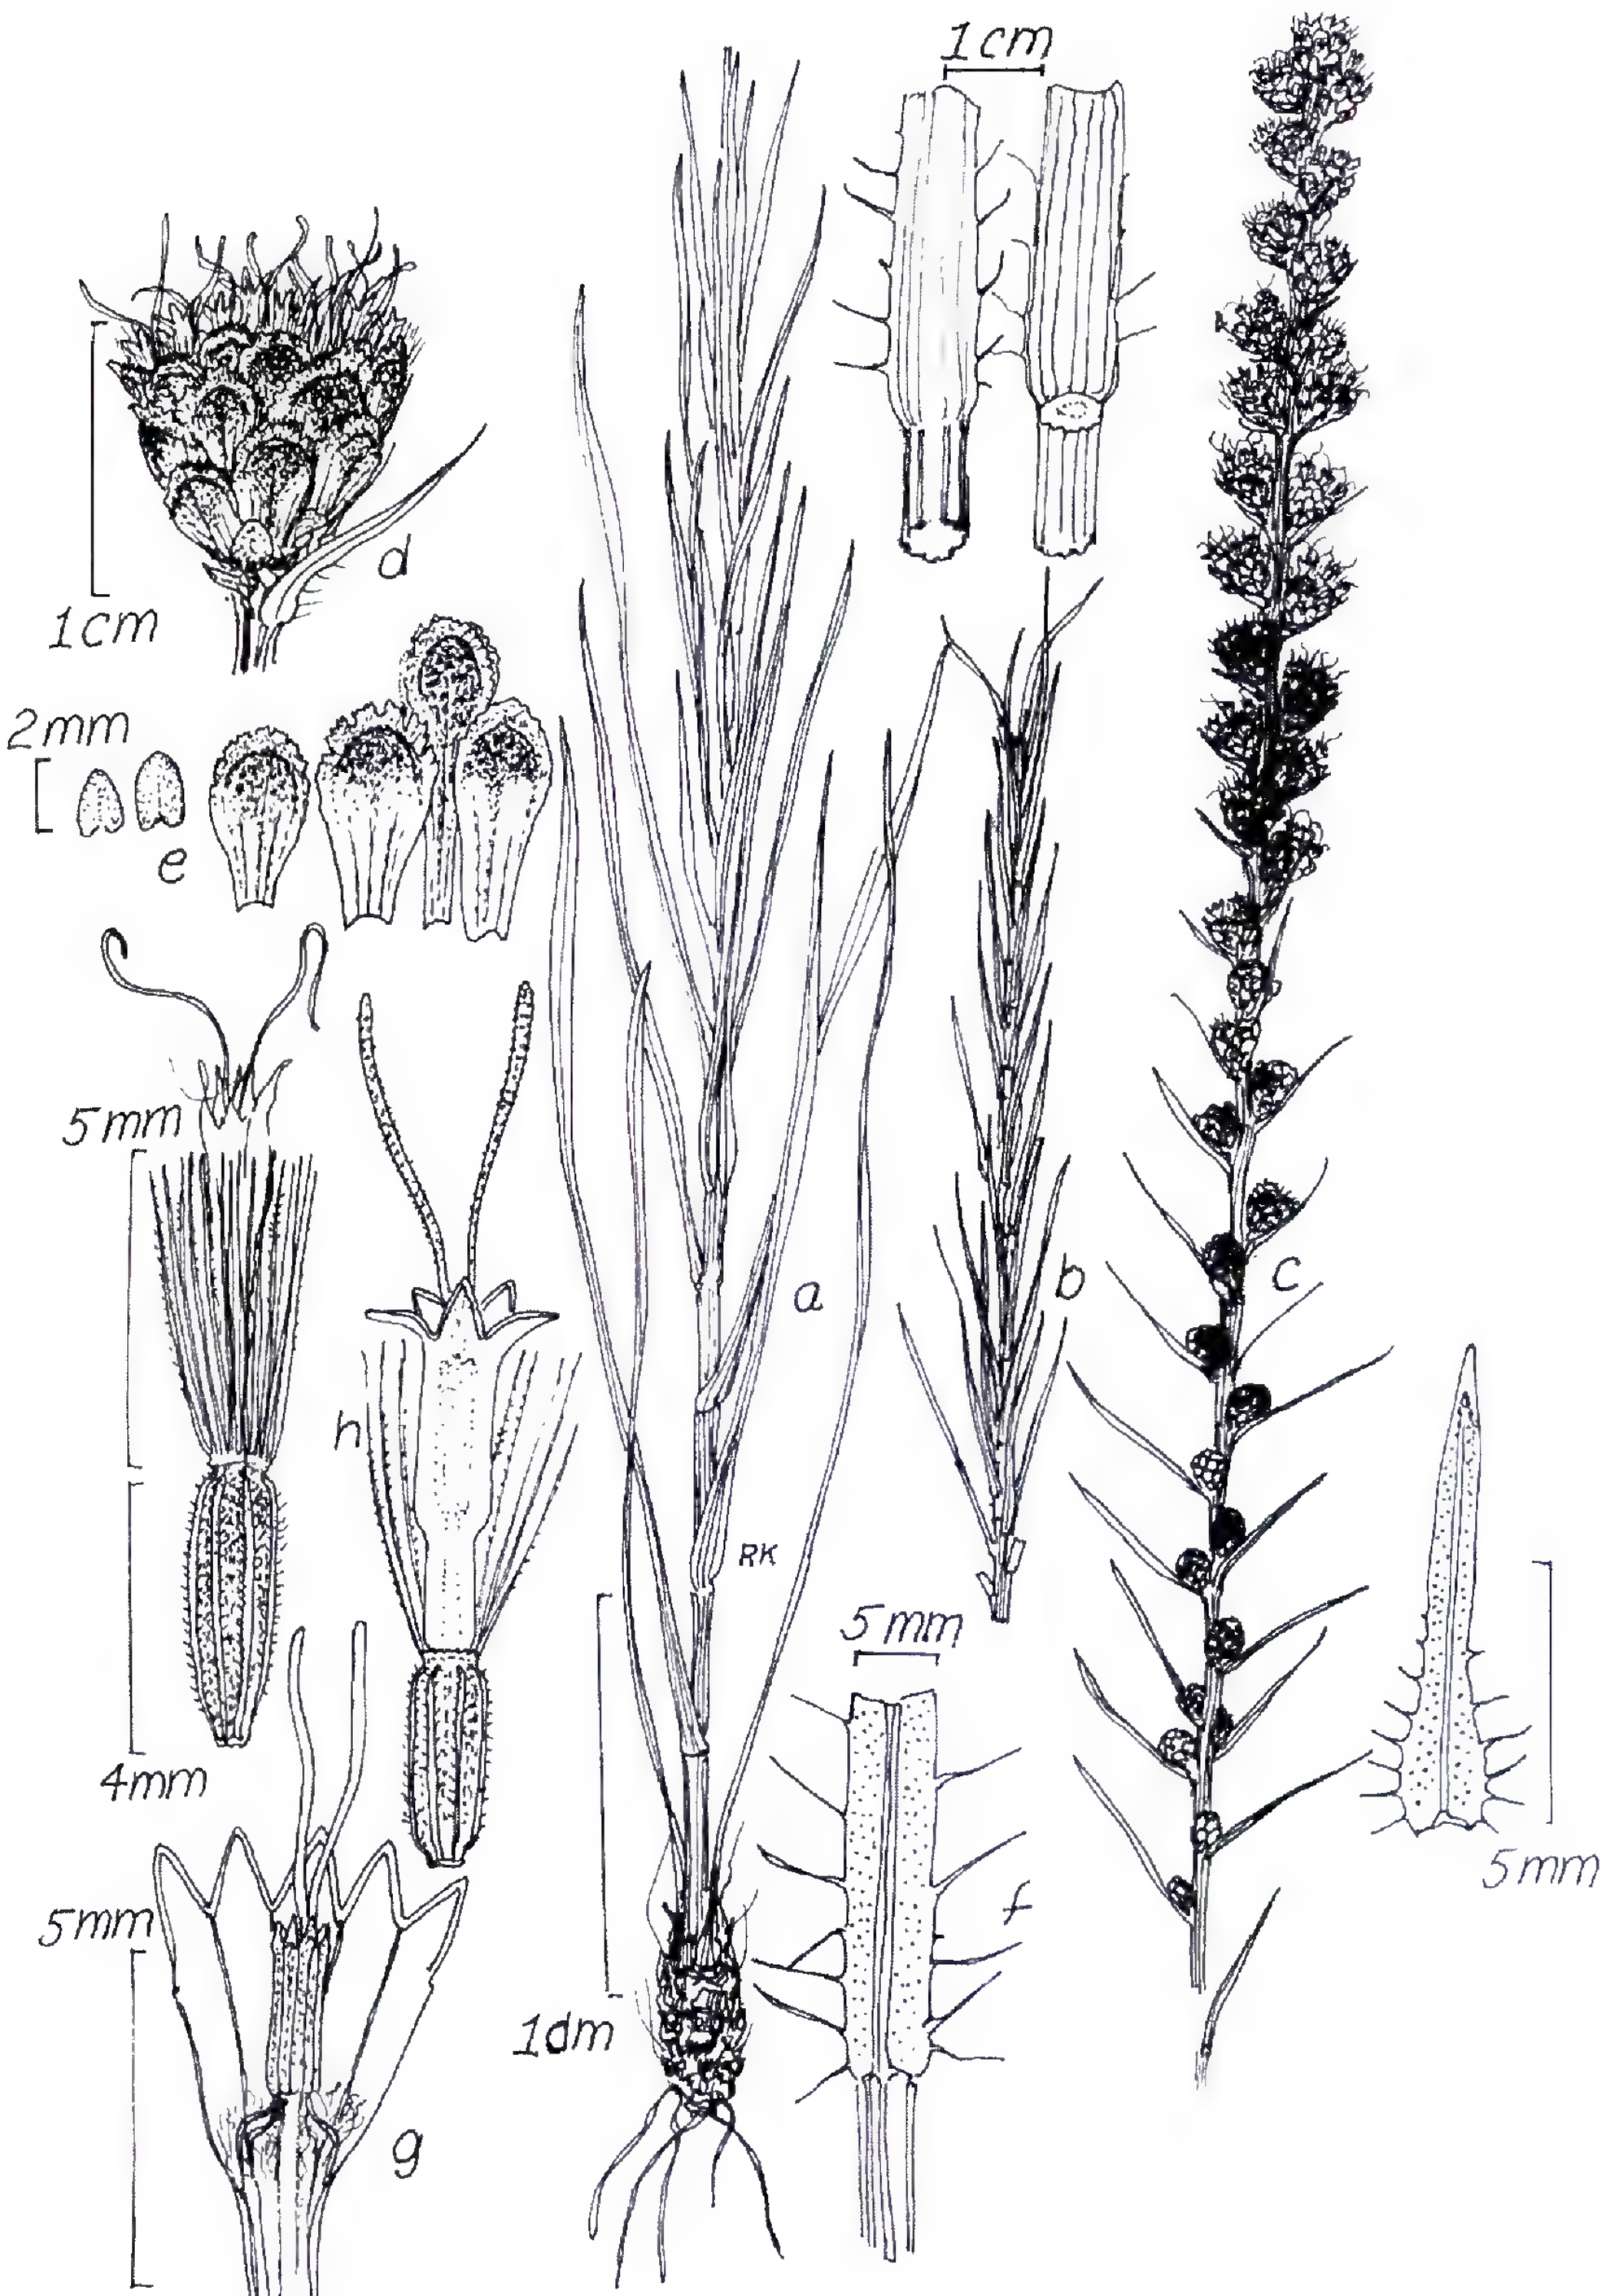

FIG. 1. *Liatris savannensis* (from the type). **a.** Habit, lower stem (at left); lower leaf base, abaxial (left) and adaxial (right) view. **b.** Midstem. **c.** Inflorescence (left), subtending bract, abaxial view (right). **d.** Head, with subtending bract. **e.** Phyllaries of a series from lowermost (left) to inner/uppermost (right). **f.** Base of midcauline leaf, abaxial side. **g.** Adaxial view of spread corolla. **h.** Fertilized floret (left); floret at anthesis (right).

der (0.2–)0.4–1 mm wide, intermittently ciliolate, the dorsal areas of longer bracts greenish to reddish-green or purple, distinctly glandular-punctate, with a sharp, low, rounded buttress delimiting the hyaline border. Florets 9–16(–17); corolla tubes at anthesis yellowish or pale with pinkish-purple lobes, sessile-glandular, tubular portion 5 mm, lobes 5, spreading, triangular, 2 mm long; internally pilose in the region of filament insertion with a broad annulus of whitish, crisped hairs. Achenes cylindric, base slightly narrowed, apex with a short neck at juncture with pappus rim, ca. 4 mm long, blackish, with ca. 10, paler, raised ribs, densely hirtellous on the ribs, sparsely so on the intervals; pappus mostly 5 mm long, bristles 30–40, pale purple-brown distally, strongly barbellate.

Etymology and habitat.—The epithet "savannensis" alludes to the savanna habitat of the species. The habitats are characterized as open sandy flats, usually moist or wet sites, dominated by slash pine, sabal palmetto, or a mixture of the two. Collections of flowering plants have been made mostly from mid-September through mid-October. Flowering less commonly may begin in August and extend into November.

Additional collections examined. **UNITED STATES. FLORIDA. Charlotte Co.:** S side of Punta Gorda on sandy peat of slash pine flatwoods bordering brackish marsh, 21 Sep 1964, *Kral 22919* (VDB, 2 duplicates distributed as *L. spicata*); sandy palmland by brackish marsh, E side of Punta Gorda, 21 Sep 1973, *Kral 51978* (FLAS, GH, MO, TEX, VDB); wet grassy clearings in pine palmetto flats by US Hwy 41, 1 mi S of Punta Gorda, 7 Oct 1979, *Kral 64561* (FSU, GH, MICH, MO, NY, TEX, VDB); abundant in marshy lands, each side of RR tracks, within city limits, S side of Punta Gorda, 29 Sep 1961, *Lakela 24684* (BRIT, FLAS, USF). **Hillsborough Co.:** Hillsborough River State Park, 20 mi NE of Tampa on US 301, 18 Oct 1977, *Arcuri 587* (USF); along Fla. Hwy 581, ca. 5 mi N of Tampa, roadside, 6 Oct 1977, *Funk 48* (USF); along SR 581, ca. 5 mi N of Tampa, 6 Oct 1977, *Gregory 18* (USF), margin of flat, open pineland with scattered palmetto, N of Tampa Air Port, Kennedy Road, 13 Sep 1961, *Lakela 24637* (USF); flat pinelands and palmetto, and along boulevards NW of International Airport, Tampa, 24 Sep 1961, *Lakela 24670* (BRIT); margin of pineland and palmetto, along US 301, ca. 1 mi S of Hillsborough River State Park, NE of Tampa, 1 Oct 1963, *Lakela 26508* (FLAS, USF); frequent along SR-581, ca 5 mi N of Tampa, 6 Oct 1977, *Lindsey 30* (USF); Rocky Creek, disturbed site near Rocky Creek and Memorial Hwy, 7 Oct 1977, *Mortellaro and Giesy 169* (USF); disturbed area at edge of oak woodland along SR-581, ca. 5 mi N of Tampa, 6 Oct 1977, *Willett 32* (USF); flat ground edge of pine flatwoods, 5 mi N of Fletcher Avenue on 30th Street, Tampa, [Oct 1977], *Winkler 36* (USF); Flatwoods Park, 2.5 mi NW of Morris Bridge, ca. 7 mi E of Lutz, pine flatwoods, 22 Oct 1994, *Wunderlin 10618* (USF). **Lee Co.:** Business Rte. 41, N of Ft. Myers, in front of public library, pine woods, 7 Nov 1985, *Brown s.n.* (USF); [no specific locality], 1 Aug 1933, *Buswell s.n.* (USF). **Manatee Co.:** Bradenton, dry sand hills, Palma Sola, 19 Aug 1945, *Gaiser, Butts, and Arnold s.n.* (FLAS). **Sarasota Co.:** T. Mabry Carlton, Jr. Memorial Reserve, pine flatwoods between wet prairies, grassy area surrounded by saw palmetto, 13 Oct 1997, *Edmondson 97-34* (USF); T. Mabry Carlton, Jr. Memorial Reserve, disturbed edge parallel to So. FPL grade, 13 Oct 1997, *Edmondson 97-35* (USF); sandy peat of open pine-palm hammock at N side of Engelwood, 7 Oct 1979, *Kral 64571* (4 duplicates, to be distributed); sandy embankments marginal to flat pinelands, 10 mi S of Venice, US 41, with *Monarda*, *Coreopsis*, and *Rhus copallina*, 20 Sep 1961, *Lakela 24648* (FLAS, USF).

Two species of series *Graminifoliae* grow in the general area of *Liatris savannensis*. *Liatris gracilis* occurs throughout Florida but grows in distinctly

drier, sandier, more upland ecological systems; it differs from *L. savannensis* in its hairy stems and peduncles, smaller, consistently short-pedunculate heads, fewer florets per head (3–6(–7)), and shorter achenes. *Liatris graminifolia* is more similar to *L. savannensis* in vestiture and head size, but the geographic range of *L. graminifolia* apparently extends southward only to the vicinity of Levy County, apparently separated by roughly 150 kilometers from the nearest known population of *L. savannensis* in Hillsborough County.

Liatris savannensis closely resembles *L. spicata* (L.) Willd., which occurs throughout Florida, and has commonly been identified as such. The two are similar in their tall stems, narrow leaves, essentially glabrous vestiture, similar-sized heads in a spicate inflorescence, and phyllaries often with a broad, scarious, pinkish rim. The first author identified his initial collections as *L. spicata*, but in 1968, going back to the material and (finally!) opening a corolla, noted pilosity within it, an annulus of crisped hairs at the level of the filament bases. We follow Gaiser (1946) in weighting the presence of this pilosity as an indicator of relationship (Nesom in prep.), with the implication that *L. savannensis* is a member of series *Graminifoliae*, and observe that similarities between *L. savannensis* and *L. graminifolia* also are strong.

The following pair of couplets outline significant morphological differences first between *Liatris savannensis* and *L. spicata* and then between *L. savannensis* and *L. graminifolia*.

couplet 1:

1. Stems minutely sessile-glandular; leaves prominently punctate, proximal margins sparsely but distinctly ciliate with hairs 1–2.5 mm long; corolla tubes pilose within at the region of filament insertion; florets 9–16(–17) per head. _____ **Liatris savannensis**
1. Stems eglandular; leaves not punctate or if so, then inconspicuously, margins eciliate or with a few scattered hairs 0.3–0.8 mm long; corolla tubes glabrous within; florets (5–)6–10(–14) per head. _____ **Liatris spicata**

couplet 2:

1. Stems minutely sessile-glandular; involucres (7–)8–10 mm high, (8–)9–11(–12) mm wide; inner phyllaries spatulate, 3.5–4 mm wide, hyaline, distinctly erose to lacerate borders (0.2–)0.4–1 mm wide; florets 9–17 per head; achenes 4–4.5 mm long. _____ **Liatris savannensis**
1. Stems eglandular; involucres 6–8(–9) mm high, 6–7.5 mm wide; inner phyllaries oblong to obovate or slightly spatulate, 1–2.2 mm wide, with hyaline, relatively smooth edged borders 0.1–0.3 mm wide; florets 6–10 per head; achenes 3–4 mm long. _____ **Liatris graminifolia**

Other differences exist between *Liatris savannensis* and *L. graminifolia* where comparisons are less diagnostic. Stems of *L. savannensis* range taller and leaves are longer. Corms of *L. savannensis* range from globose to elongate; we have observed only globose corms in *L. graminifolia*. The basal and lower cauline leaves of *L. savannensis* are essentially strap-shaped (lorate), usually with little increase in width distally, while similar leaves of *L. graminifolia* almost always

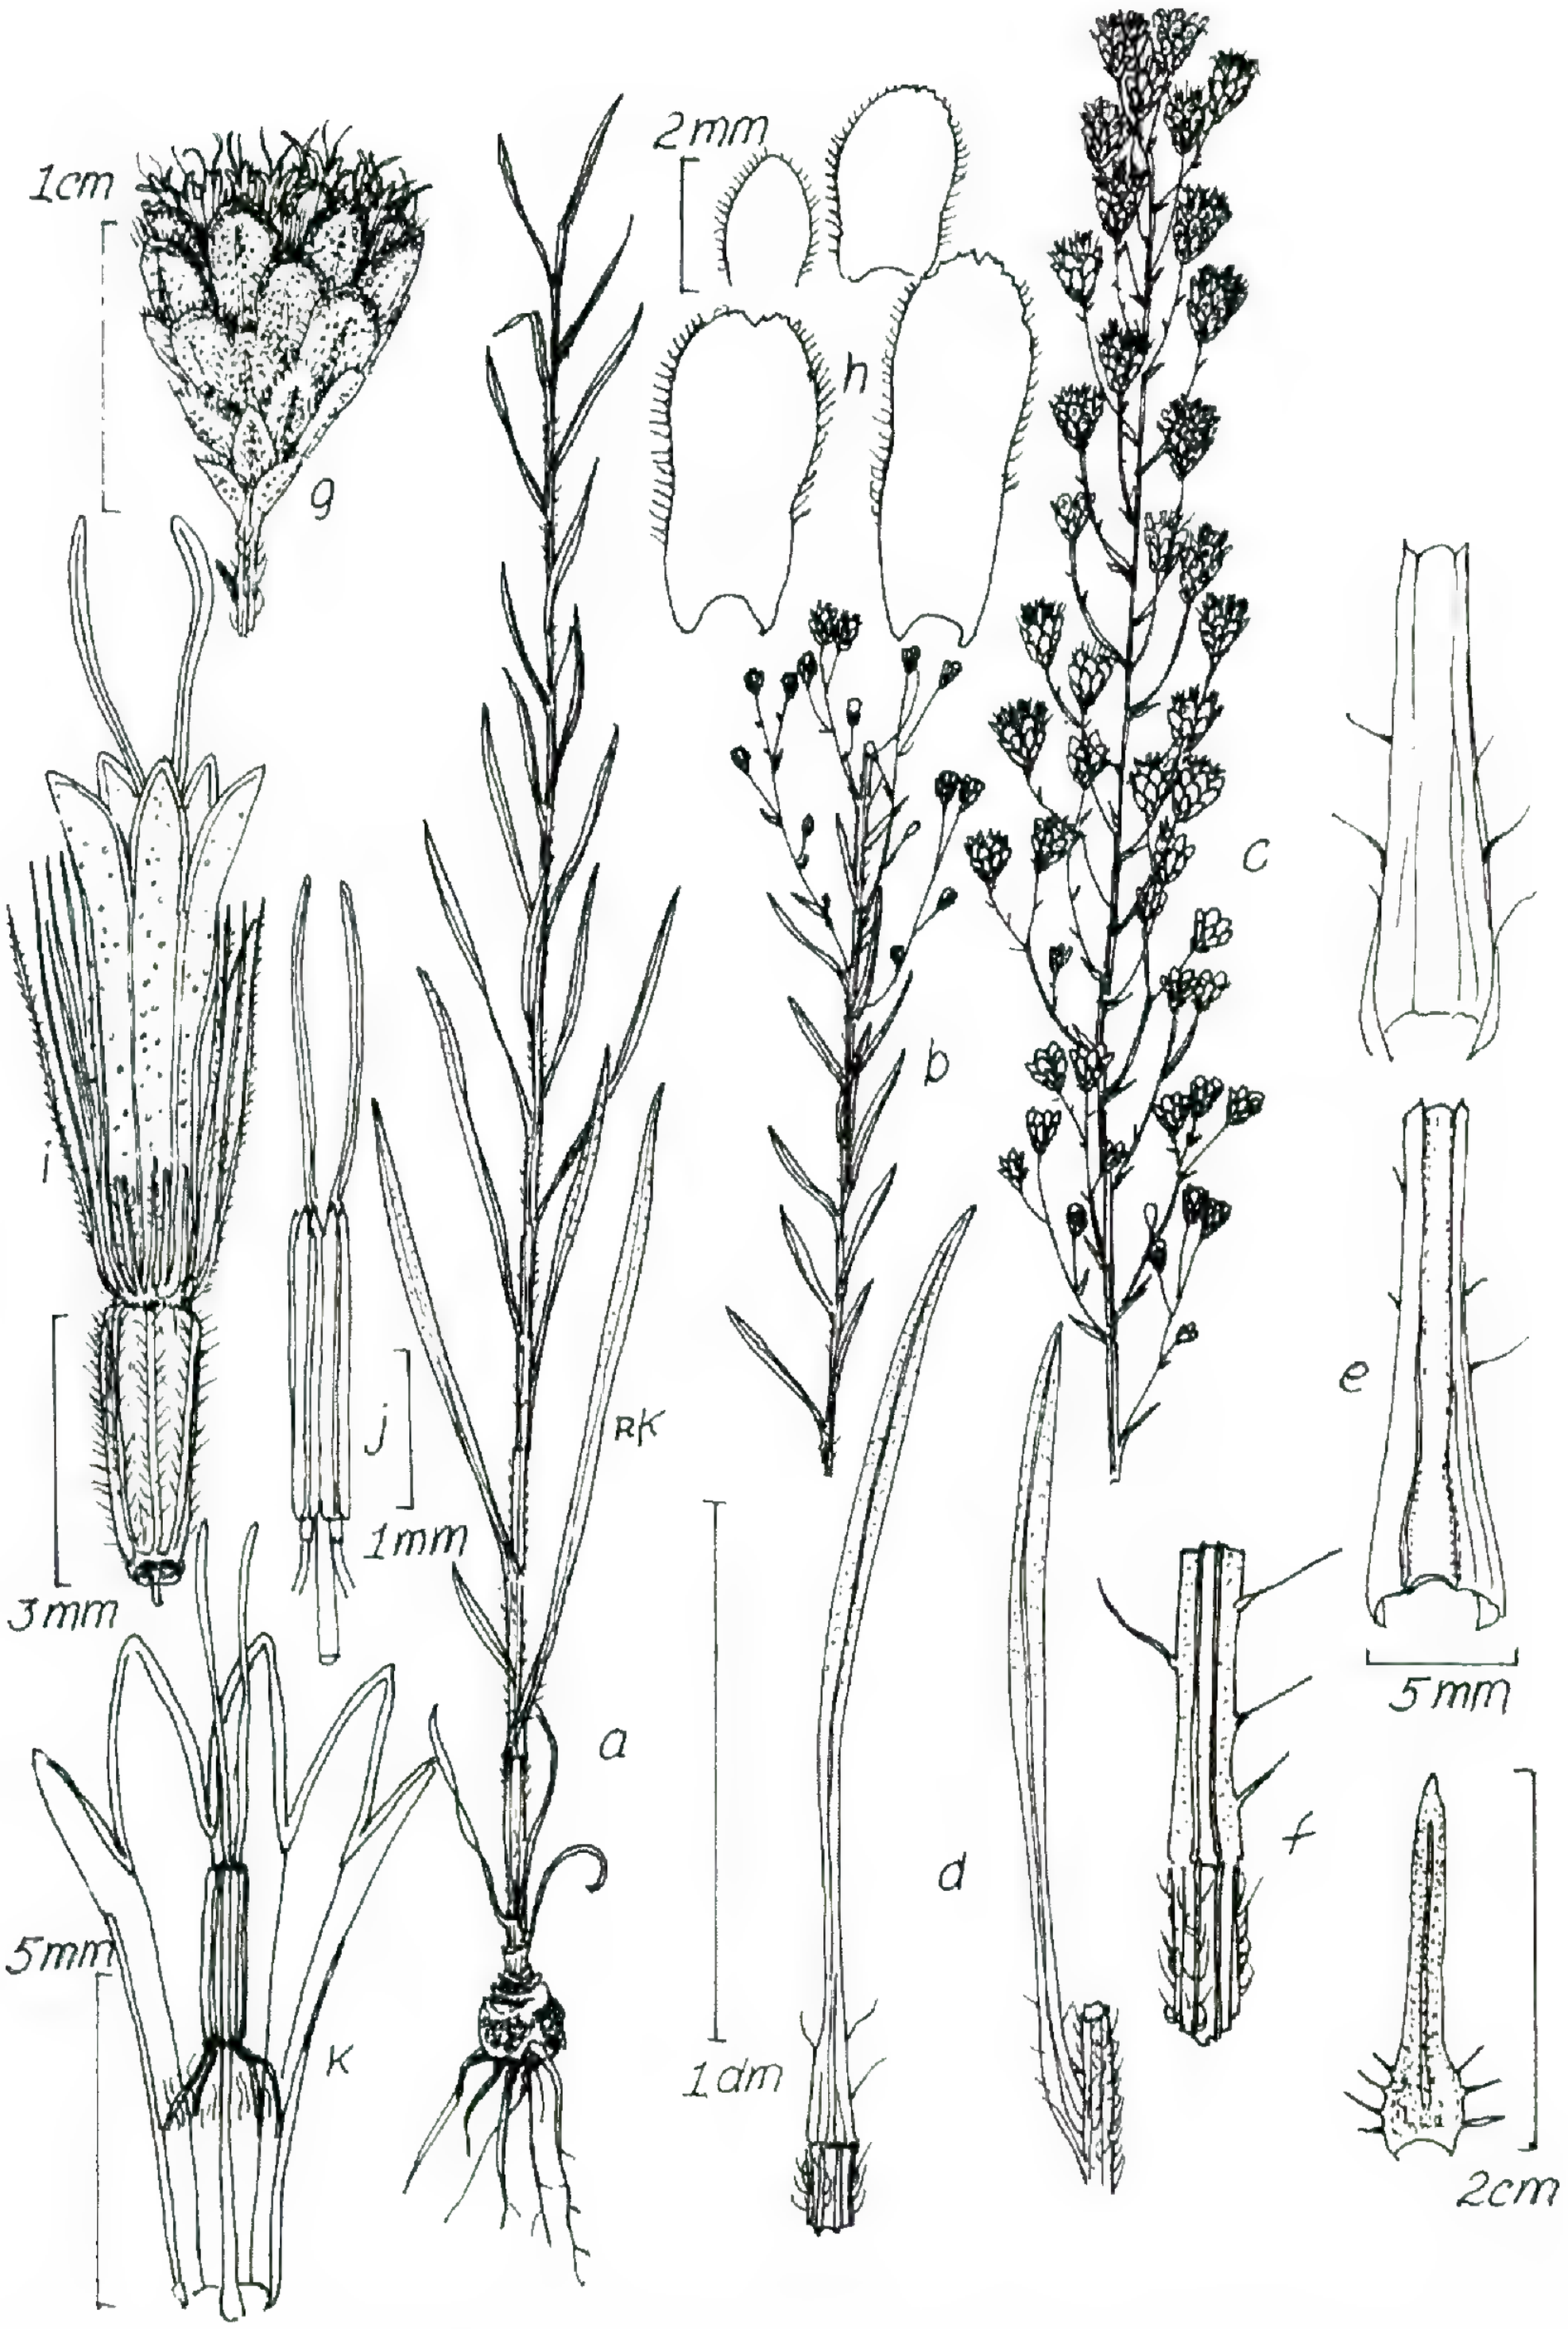

FIG. 2. *Liatris patens* (from *Kral 56936*). **a.** Habit, rootstock and lower half of plant. **b.** Upper leafy part of stem and inflorescence base. **c.** Middle and upper part of inflorescence. **d.** Basal leaf, abaxial view (left), adaxial view (right). **e.** Base of a basal leaf, abaxial side (below), adaxial side (above). **f.** Base of median cauline leaf, abaxial side (left), a lower bracteal leaf (right). **g.** Head in anthesis. **i.** A recently fertilized floret. **j.** Anther tube with exserted style branches. **k.** A spread mature corolla, inside view.

show a distinct petiolar portion in the lower 1/4–1/2 of the total leaf length, distinctly widening into a 'blade' portion. Heads of *L. savannensis* are consistently sessile or on shorter peduncles (peduncles 0–2 mm long) compared to slightly longer ones, on average, in *L. graminifolia* (peduncles 0–3(–7) mm long). In addition to differences in overall phyllary size and margin, the medial, green, glandular-punctate portion of *L. savannensis* phyllaries is consistently raised above the hyaline border by a low, rounded ledge similar to that commonly seen in the large heads of *L. scariosa* (L.) Willd., which is perhaps closely related to ser. *Graminifoliae*.

Liatris graminifolia occurs over a wide area and in various habitats (especially northward), but meaningful infraspecific taxa are difficult to recognize, and comparisons to it in the present study refer to the species as a whole. Southern elements of *L. graminifolia* have phyllaries that are distinctly obovate to subspatulate, similar to those of *L. savannensis*, in contrast to oblong phyllaries, which are characteristic of plants from the northern part of the range of the species (roughly South Carolina and northward, see Fig. 3). The southern plants have been recognized as *L. graminifolia* var. *elegantula* (Greene) K. Schum. (the type from Alabama), but intergradation in phyllary morphology occurs over a wide area and oblong phyllaries are found even in some southern populations. Some descriptions of *L. graminifolia* have attributed more variability in vestiture and floret number to the species than we do, but it seems likely that these descriptions included the two species recognized and segregated for the first time in the present study.

A second previously undescribed species of *Liatris* has been recognized primarily on the basis of herbarium studies connected with preparation of a taxonomic treatment of the genus for the developing Flora of North America (FNA) volumes.

Liatris patens Nesom & Kral, sp. nov. (**Fig. 2, 3**). TYPE: UNITED STATES. GEORGIA. Laurens Co.: drier margins of wet sandy meadow 9 mi E of Dublin, 300 ft elev., 19 Oct 1947, *A. Cronquist 4876* (HOLOTYPE: BRIT).

Liatri graminifoliae similis capitulis comparative grandibus et flosculis numerosis, differt pedunculis longioribus et caulibus ac pedunculis hirtelli-strigosis; *Liatri gracili* similis capitulis consistente peduncularibus et caulibus ac pedunculis pubescentibus, differt pedunculis longioribus et capitulis majoribus flosculis numerosioribus.

Plants perennial, arising from a globose to depressed-globose corm 7–14 mm in diameter. Stems stiffly erect, 35–95 cm tall; stems and peduncles moderately to densely hirtellous-strigose with antrorsely curved, ascending-appressed, multicellular white hairs 0.2–0.4 mm long. Leaves punctate-glandular, glabrous except sparsely ciliate along 1–5 mm of the proximal margins; basal and lower cauline narrowly oblanceolate to linear-oblanceolate, 9–18 cm long, narrowed to a petiolar portion 1/4–1/2 the leaf length, the broader (blade) portion 2–4(–

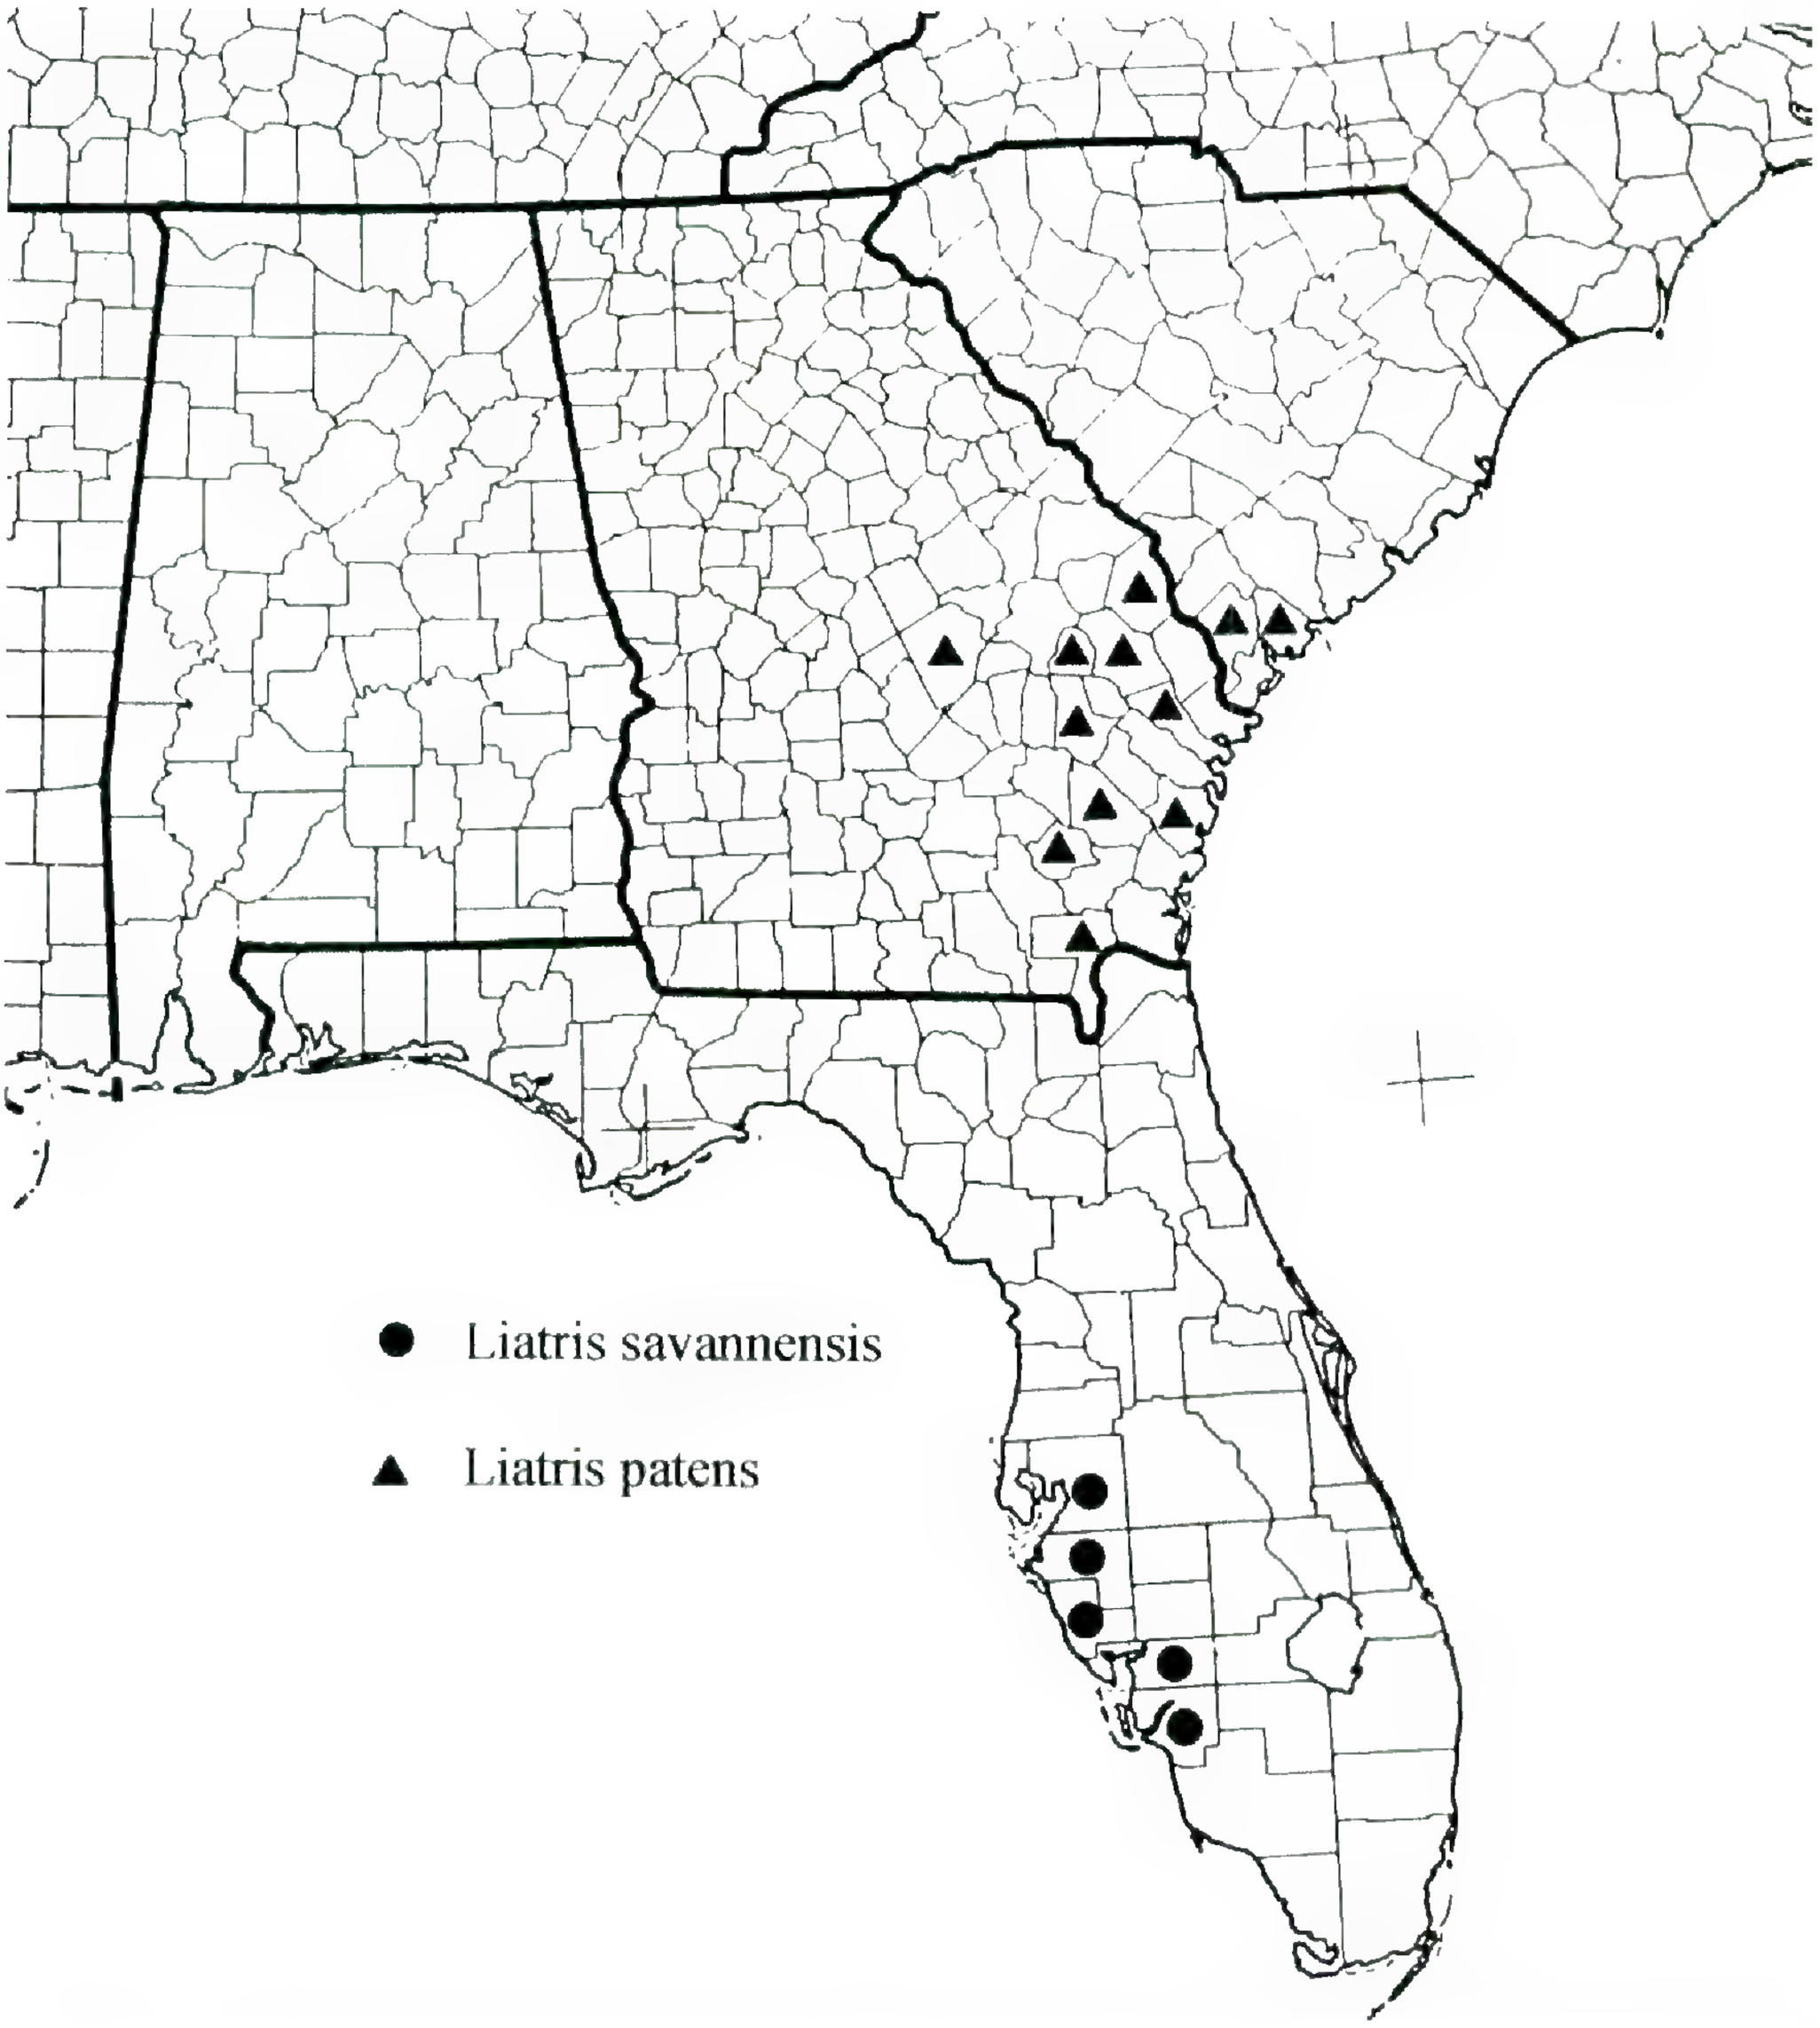

FIG. 3. Geographic distribution of *Liatris savannensis* and *Liatris patens*.

7) mm wide, gradually or abruptly becoming much shorter and linear, upper cauline 1–2 cm long, ca. 0.5 mm wide, grading into inflorescence bracts. Inflorescence racemose, determinate, forming a loose column (10, 20–)25–40 cm long, 3–6 cm wide. Heads erect or nearly so, on divergent-ascending peduncles 1–2.5(–3) cm long, peduncles initially diverging from the inflorescence axis at angles of 45–90 degrees, subtended by a linear bract 5–12 mm long, minutely subulate-bracteate, rarely (especially above damage and mostly on lower peduncles) 1–2-branched; involucres turbinate-campanulate, (5–)6–7.5 mm high, 5–7 mm wide (pressed); phyllaries in (2–)3–4(–5) series, strongly graduate in length, erect,

nearly flat, green with an evident midvein, broadly obovate to broadly oblong-obovate, apex rounded to nearly flat, innermost 1.5–2.5 mm wide, (5–)6–7.5 mm long, outermost mostly ovate, ca. 1/5–1/3 as long as the inner, all evenly punctate-glandular, outer sparsely strigose-villous with white hairs like those on the peduncles, inner glabrous, margins hyaline and pinkish-purple (like the corollas), 0.1–0.3 mm wide, even to slightly erose, usually densely ciliate. Florets 7–12; corollas pinkish-purple, sessile-glandular, tubular portion 4–5(–6) mm long, lobes 5, spreading, narrowly triangular, 2–2.5 mm long; internally pilose in the region of filament insertion with a broad annulus of whitish, crisped hairs. Achenes obtriangular in outline, slightly flattened, with ca. 10 nerves, 2.5–2.8 mm long, densely but weakly hirsute on nerves and intervals; pappus 5–6 mm long, usually equal or longer than the corolla tubes, bristles strongly barbellate, distally purplish.

Etymology and habitat.—The epithet "patens" alludes to the spreading, relatively long peduncles characteristic of the species. Collections have been made in sandy pinelands of southeastern Georgia and adjacent South Carolina, apparently mostly commonly in moist sites. Known collections have been made in late September through November.

Additional collections examined. **UNITED STATES. GEORGIA. Bryan Co.:** Fort Stewart Military Reservation, Training Area C18, N side of Fort Stewart Road 58, ca. 1.8 mi E of jct with Georgia Rte. 67; occasional on disturbed sandhill, 5 m elev., with *Vaccinium myrsinites*, *Quercus geminata*, 25 Sep 1992, *Zebryk 672* (VDB). **Bulloch Co.:** 4.5 mi NW of Portal in open wooded area, 12 Oct 1962, *Boole 1311* (BRIT, TEX, US). **Candler Co.:** sandy longleaf pineland above bog by hiway, ca. 3 mi NW of Aline, 9 Oct 1975, *Kral 56936* (VDB). **Charlton Co.:** plentiful in open disturbed area [along] Ga 177, 13 mi NE of Edith, 8 Oct 1966, *D'Arcy 1223* (VDB). **McIntosh Co.:** sandy flatwoods along US 17, near Middleton Church at Eulonia, 20 Oct 1987, *Angerman s.n.* (USCH); clearcut woods on north side of Eulonia, 20 Oct 1987, *Angerman s.n.* (USCH). **Pierce Co.:** sandy rise in pine flatwoods, 10 mi N of Bristol on Ga. 15, 11 Oct 1991, *Kral 79978* (VDB); sandy pineland by US 301, S side of Jesup by Landmark Motel, 9 Oct 1975, *Kral 59916* (VDB). **Screven Co.:** ca. 2 mi from Blue Springs near a "Carolina Bay," 10 Oct 1959, *Boole 997* (BRIT). **Tattnall Co.:** ca. 5 mi from Tattnall-Bryan County line on Route 280 from Claxton, 17 Oct 1959, *Boole 1018* (BRIT). **Wayne Co.:** sandy peat of pine-palmetto flats, by US 341, 2 mi NW of Everett, 1 Oct 1976, *Kral 59205* (VDB). **SOUTH CAROLINA. Beaufort Co.:** N of Victoria Bluffs Heritage Preserve, near Victoria Bluffs development, N of Rte. 278, N of Bluffton, local, along roadside through *Pinus palustris/Pinus elliottii/Serenoa repens* flatwoods on sandy spodosol soils, 4 Nov 2001, *McMillan 6055* (CLEMS). **Jasper Co.:** UTM 498600 E, 358900 N, *Pinus palustris/Pteridium/Quercus pumila/Aristida* flatwoods combining elements of both mesic and dry areas, 10 Aug 1995, *McMillan 1101b* (USCH).

Collections of *Liatris patens* have previously been identified as *L. graminifolia* or *L. gracilis*, both of which appear to be sympatric with the new species (Fig. 3). The apparent geographical coherence of *L. patens*, recorded here for ten counties in Georgia and two in South Carolina, is matched by its morphological consistency. *Liatris patens* is similar to *L. gracilis* in its cauline and peduncular vestiture and its pedunculate heads, but the new species has larger heads with more numerous florets and the peduncles are longer and arch upward to bear

erect or nearly erect heads. *Liatris patens* is similar to *L. graminifolia* in its relatively large heads and number of florets but different in its hirtellous-strigose stems and peduncles and long-pedunculate heads in a broadly racemoid inflorescence. Peduncles of *L. graminifolia* often are slightly elongate (0–3(–7) mm), sometimes more in plants with damaged stems, but the peduncles are almost always straight and divergent at ca. 45 degrees.

Distinctions among *Liatris patens* and close relatives are summarized in the following contrasts.

1. Stems and peduncles glabrous or nearly so; heads usually sessile or on short (0–3(–7) mm) peduncles, usually in a densely spiciform arrangement; involucres 7–12 mm high; florets 6–14 per head. ____ **Liatris graminifolia**
1. Stems and peduncles distinctly hirtellous-strigose with white hairs; heads on divergent, arcuate-ascending peduncles and loosely racemoid or nearly sessile but spreading; involucres (4–)5–7.5 mm high; florets 3–6(–7) or 7–12 per head.
   2. Peduncles (0–)2–10(–12) mm long, straight or slightly ascending; involucres cylindric-campanulate, (4–)4.5–6(–7) mm high, 3–4(–5) mm wide; florets 3–6(–7) per head. ____ **Liatris gracilis**
   2. Peduncles 10–25(–30) mm long, arching-ascending; involucres turbinate-campanulate, (5–)6–7.5 mm high, 5–7 mm wide; florets 7–12 per head. ____ **Liatris patens**

ACKNOWLEDGMENTS

We greatly appreciate the help of Bruce Hansen and Richard Wunderlin, who sent us photocopies of the collections of *Liatris savannensis* housed at USF, John Nelson, who sent photocopies of the USCH collections of *L. patens* from McIntosh Co., Ga., and Patrick McMillan, who sent a photocopy of the CLEMS collection from Beaufort Co., S.C. The collection citations from those institutions are based on the photocopies, which are filed in the BRIT herbarium. A loan of specimens was received from FLAS. The distinction of *Liatris patens* also has been recognized by Melanie DeVore, who began a study of the genus in connection with an FNA treatment but subsequently moved to other responsibilities. Bruce Hansen and the editor provided useful comments on the manuscript. We note that although neither species described here appears to be rare, at least during the periods when most of the collections were made, both are restricted in range and their conservation status needs to be evaluated by local and regional field study.

The Botanical Garden I and II is an impressive two volume set of modern day botany. It is billed as "a spectacular hybrid of gardening book and scientific text, with expert commentary..." Not only will one enjoy the beautiful photography, but there are interesting comments to read ranging from scientific and useful to fascinating and practical information. I'm glad to see that the toxic nature of some of the most common garden plants is discussed. The two volumes are fascinating and fun to browse or to search for specific plants and information. I've already found some interesting facts that will be useful in a future lecture. Enjoy!

Each taxonomic entry contains **Name** (genus, species and common names, date of discovery, and range), **Description** (detailed and concise in the scientific style), **Key Recognition Features**, **Evolution and Relationships**, **Ecology and Geography**, and **Comments**.—*Barney Lipscomb, Botanical Research Institute of Texas, 509 Pecan St, Fort Worth, TX 76102-4060, U.S.A., barney@brit.org.*

NEW COMBINATIONS IN *XANTHISMA* (ASTERACEAE: ASTEREAE)

Guy L. Nesom

Botanical Research Institute of Texas
509 Pecan Street
Fort Worth, TX 76102-4060, U.S.A.

ABSTRACT

Xanthisma incisifolium (I.M. Johnston) Nesom, comb. nov. (*Machaeranthera pinnatifida* var. *incisifolia* = *Machaeranthera incisifolia*), and **Xanthisma glaberrimum** (Rydb.) Nesom & O'Kennon, comb. nov. (*Machaeranthera pinnatifida* var. *glaberrima*), are transferred at specific rank to the genus *Xanthisma*, newly expanded by Morgan and Hartman to include species segregated from *Machaeranthera* sensu stricto.

RESUMEN

Xanthisma incisifolium (I.M. Johnston) Nesom, comb. nov. (*Machaeranthera pinnatifida* var. *incisifolia* = *Machaeranthera incisifolia*), y **Xanthisma glaberrimum** (Rydb.) Nesom & O'Kennon, comb. nov. (*Machaeranthera pinnatifida* var. *glaberrima*), se transfieren con rango específico al género *Xanthisma*, ampliado de nuevo por Morgan y Hartman para incluir especies segregadas de *Machaeranthera* sensu stricto.

Molecular evidence (Morgan 2003) indicates *Machaeranthera* Nutt. sensu lato (Hartman 1990) is not monophyletic if the genera *Oonopsis* Nutt., *Pyrrocoma* Hook., and *Xanthisma* DC. (sensu Semple 1974) are excluded from it. In consequence, Morgan and Hartman (2003) have restricted *Machaeranthera* to two species and assigned the remaining species to three other genera, including *Xanthisma*. The latter is enlarged by Morgan and Hartman from a monospecific taxon to one including 17 species, and two additional taxa at specific rank are formally recognized here. Each of those added here is a member of the *Xanthisma spinulosum* (Pursh) Morgan & Hartman complex (= *Machaeranthera pinnatifida* sensu lato) and has been treated at varietal rank by Turner and Hartman (1976), Hartman (1990), and Morgan and Hartman (2003).

Xanthisma incisifolium (I.M. Johnston) Nesom, comb. nov. BASIONYM: *Haplopappus arenarius* Bentham var. *incisifolius* I.M. Johnston, Proc. Calif. Acad. Sci., ser. 4, 12:1190. 1924. *Machaeranthera pinnatifida* (Hook. f.) Shinners var. *incisifolia* (I.M. Johnston) Turner & Hartman, Wrightia 5:315. 1976. *Machaeranthera incisifolia* (I.M. Johnston) Nesom, Phytologia 69:112. 1990. *Xanthisma spinulosum* (Pursh) Morgan & Hartman var. *incisifolium* (I.M. Johnston) Morgan & Hartman, Sida 20:1409. 2003.

SIDA 20(4): 1585–1588. 2003

This Mexican taxon was earlier treated at specific rank (Nesom 1990), where it was noted that it is morphologically non-intergrading with other 'phases' of the *Machaeranthera pinnatifida* complex. It is restricted to San Lorenzo Island of Baja California Norte and the islands of San Esteban and Tiburón of Sonora.

Xanthisma glaberrimum (Rydb.) Nesom & O'Kennon, comb. nov. BASIONYM: *Sideranthus glaberrimus* Rydb., Bull. Torrey Bot. Club 27:621. 1900. *Machaeranthera pinnatifida* (Hook. f.) Shinners var. *glaberrima* (Rydb.) Turner & Hartman, Wrightia 5:311. 1976. *Xanthisma spinulosum* (Pursh) Morgan & Hartman var. *glaberrimum* (Rydb.) Morgan & Hartman, Sida 20:1408. 2003.

Xanthisma glaberrimum is an entity of the Great Plains, occurring from the Texas panhandle region northward into southeastern South Dakota and extreme west-central Minnesota. *Xanthisma spinulosum* (var. *spinulosum*) borders the distribution of *X. glaberrimum* on the south, west, and north. Turner and Hartman (1976, p. 311) observed that "Populations of [*X. glaberrimum*] seem fairly well-marked throughout most of Kansas and Nebraska and southern South Dakota, but to the western periphery of these regions they intergrade over a broad area into [*X. spinulosum*], especially in Oklahoma and the panhandle region of Texas." The somewhat contrasting observation is made here that reproductive isolation in this area of sympatry is at least as significant as intergradation, and in view of its morphological distinction and apparent isolation, a balance of evidence indicates that recognition at specific rank is appropriate for *Xanthisma glaberrimum*.

In recent floristic studies centered in Hutchinson, Moore, and Potter counties of the Texas panhandle (Nesom and O'Kennon in prep.), we have observed many sites where populations of *Xanthisma glaberrimum* and *X. spinulosum* grow in close proximity without intermediacy. A large array of herbarium collections also indicates that two morphological 'nodes' exist in this region (see contrasts in key below) and confirms the field experience. Evidence of introgression is seen, but even in such instances, *X. spinulosum* that shows characteristics of *X. glaberrimum* remains distinct from the latter at a population level, indicating the existence of reproductive isolation. For example, from Hutchinson County, *Nesom & O'Kennon 164* and *165* (BRIT) represent populations of *X. glaberrimum* (in typical form) and *X. spinulosum* (with strict, few-branched stems, similar to *X. glaberrimum* in habit but glandular and densely tomentose) that were growing at the same site—the two entities were distinct, with no intermediates observed in the field. Without the apparent introgression, the distinction is even more obvious. The direction of introgression appears to be primarily toward *X. spinulosum*—this species shows greater inter-populational variability, especially when it occurs in close proximity to *X. glaberrimum*, while the latter maintains a more stable morphology. In our field work, we have referred to these as the "gray thang" (= *X. spinulosum*) and "green thang" (= *X.*

glaberrimum) and rarely find it necessary to get closer than 5 meters to make an identification.

Collections at BRIT indicate that both taxa coexist in at least 10 of the 20 counties in the upper Texas panhandle region—this is considerably more of a mix than shown by the map in Turner et al. (2003). Herbarium material at BRIT indicates that a broad area of sympatry also occurs in adjacent Oklahoma. The area of sympatry was not indicated by the map in Turner & Hartman (1976, Fig. 42), and the Atlas of the Flora of the Great Plains (Great Plains Flora Association 1976) made no distinction between *Machaeranthera pinnatifida* var. *pinnatifida* and var. *glaberrima*.

Turner and Hartman (1976, p. 311) noted that "In eastern Wyoming, eastern Colorado, eastern New Mexico and the panhandle of Texas, the more typical, mostly pubescent, populations [of *Machaeranthera pinnatifida* var. *pinnatifida*] pass into the var. *glaberrima*, the two varieties often occurring near one another, but it is believed that this has resulted primarily from migration along road shoulders in relatively recent time, of var. *pinnatifida* into the regions of var. *glaberrima*, and perhaps vice versa." In contrast, however, Nesom and O'Kennon observe that the two taxa grow both with and without the other at many sites that appear to be relatively undisturbed and that are relatively distant from highway sides. The kind of morphological intergradation seemingly implied by the phrase "pass into" would be the impression from study of herbarium collections and reflect the recognition of gene flow (as also postulated above). Only the repeated field experience led us to interpret this intergradation with further perspective, and it is significant that Turner and Hartman's observation that the two occur "near one another" agrees with our own.

1. Stems usually unbranched until the upper third, the heads usually distinctly clustered; leaves strictly ascending, narrowly oblong in outline, 1-pinnatifid, midportion 1–2(–2.5) mm wide, lobes oblong-lanceolate to lanceolate or triangular, sometimes shallowly toothed, glabrous or less commonly lightly tomentose, eglandular or less commonly glandular; involucres cupulate. _____ **Xanthisma glaberrimum**
1. Stems branched from midstem or below to the upper third, the heads diffusely arranged; leaves loosely ascending to spreading, oblong to obovate in outline, especially the basal and lower cauline, 1–2-pinnatifid, midportion 0.5–1(–1.5) mm wide, lobes linear to lanceolate, usually shallowly toothed, usually glandular to varying degrees, slightly to densely tomentose, rarely without eglandular hairs; involucres shallowly hemispheric. _____ **Xanthisma spinulosum** var. **spinulosum**

Plants of *Xanthisma glaberrimum* with light tomentum were annotated in 1971 by R.C. Jackson as "var. *glaberrima* > subsp. *wootonii* (Greene) Jackson" (the combination by Jackson never published), but the type of *Eriocarpum wootonii* Greene was collected in the White Mountains of Lincoln Co., New Mexico, and is part of *X. spinulosum*. Its similarity in vestiture to some plants of *X. glaberrimum* is interpreted here as parallel. It seems likely that relatively un-

common plants of *X. glaberrimum* showing glandularity reflect gene flow from *X. spinulosum*, although their close relationship also suggests that parallelism is a possibility. Differences in pappus morphology noted by Turner and Hartman (1976) between *X. glaberrimum* and *X. spinulosum* have not been confirmed in the present study.

ABSTRACT

A new goldenrod, *Solidago arenicola*, has been discovered from Blount County, Alabama. It is hereby described, figured, and contrasted with three other *Solidago* species, *S. plumosa* Small, *S. simplex* Kunth, and *S. erecta* Pursh, all of which have similar morphologies and are from the southeastern U.S.

RESUMEN

Una nueva vara de oro, *Solidago arenicola*, ha sido descubierta en el condado de Blount de Alabama. Aquí se describe, se ilustra y se contrasta con otras tres especies de *Solidago*, *S. plumosa* Small, *S. simplex* Kunth y *S. erecta* Pursh, que son del suroeste de los Estados Unidos y tienen morfologías similares.

The description below is based on several specimens, all from the same locality, which is the only locality from which *S. arenicola* has been collected to date. The collections were made along the Locust Fork River in Blount County, Alabama. The habitat at this location is shady, acidic woods in deep sandy alluvium on the river flood plain. These woods are commonly inundated by swiftly flowing water when the river overflows following heavy rains during the winter and early spring months. The drier summer and fall months aided by the porous sandy alluvium bring about a relatively dry substrate as the river recedes to a very small sluggish flow, well within the main channel.

Solidago arenicola B.R. Keener & Kral, sp. nov. (**Fig. 1**). TYPE: U.S.A. ALABAMA. Blount Co.: along E side of Locust Fork Branch of Black Warrior River, 0–1/4 mi S of Swann Bridge and ca. 1 mi W of Cleveland by Swann Bridge Road, 7 Sep 2002, *R. Kral 93190 & B.R. Keener* (HOLOTYPE: US; ISOTYPES: F, GA, MO, NCU, NY, TENN, UNA, USCH, VDB, WAT).

Planta inter *S. plumosa* Small et *S. simplex* Kunth et vars et *S. erecta* Pursh, species America borealis orientalis; differt a *S. plumosa* caulibus brevioribus, foliis basalibus brevioribus in ambitubus (ad apicem) latioribus, inflorescentiis angustioribus, acheniis longioribus; differt a *S. simplex* foliis pleurumque latioribus, involucris altioribus, acheniis longioribus et glabris; differt a *S. erecta* capitulis paucioribus, involucris altioribus; floribus disciformibus numerosioribus, corollis disciformibus longioribus.

FIG. 1. *Solidago arenicola* B.R. Keener & Kral (from the type). **A.** Habit. **B.** Lower cauline leaf, abaxial view. **C.** Lower cauline leaf, adaxial view. **D.** Midcauline leaf, abaxial view. **E.** Uppermost cauline leaf, adaxial view. **F.** Head and upper portion of peduncle. **G.** Lower phyllary bract. **H.** Median phyllary. **I.** Inner phyllary. **J.** Ray floret. **K.** Disc floret post anthesis (left); expended anther.

Perennial (35–)40–80 cm tall from a short, horizontal to ascending rhizome, this and its branches apically caudex-like, to 5 mm thick, mostly imbedded in imbricated chaffy bases of older leaves. Stems erect, single or 2–3 approximate from rhizomal branches, terete, 2–4 mm thick at base, shallowly multicostate, glabrous save in inflorescence and its branches, there sparely to moderately hirtellous with short (0.2 mm or less), narrowly triangular, spreading or antrorsely curved multicellular hairs. Leaves alternate in high spiral, ascending to erect, margins coarsely scabro-ciliate, with ciliae antrorsely incurved and claw-like, the basal and lowermost leaves mostly spathulate to oblanceolate, 10–15 cm × 1.5–4 cm, blade below middle entire, gradually attenuate, to a slightly dilated clasping base, distal margins supramedially, coarsely ascending-serrate with long, shallowly convex or level-backed shallow teeth, apices acute to narrowly rounded, often to short, brownish, callused tips; distal cauline leaves gradually narrowing and shortening, ranging progressively to narrowly oblanceolate or narrowly elliptic, with apices more narrowly acute, margins entire, the uppermost 3.5–6 cm × 6–10 mm, there grading to widely ascending to spreading or even reflexed bracteal leaves; leaf surfaces glabrous, adaxially deep green with only the impressed midvein evident, abaxially pale with midvein raised and with sharply contrasting level network of deep green vein reticulum. Heads arranged into racemose or narrowly paniculate inflorescences, mostly with primary branches widely to narrowly ascending, the lowest usually longest with longer (often reflexed) bracts, from nodes 2–4 cm distant, and most floriferous, progressively shorter, becoming simple or with few-headed cymules, or primary axis simply a raceme of heads. Ultimate penduncles stiffly, widely ascending, angulate, slightly compressed, ca. 0.5 mm thick, stubby-bracteolate, scattered-hirtellous. Heads radiate, essentially turbinate, mature involucres 7–9 mm high, 0.7–1 cm wide at distal most point, phyllaries loosely spirally imbricate, 1–1.3 mm wide with pale, scarious-edged borders, and abaxially sunken midrib, this bordered by a narrow green band dilating apically to a narrow diamond, around a pale, elliptic depression, all with pilose-ciliate apices, lower ones 3–3.5 mm long, transitional from peduncular bracts, more green and shorter than upper, gradually grading to 5–6 mm, narrower, more acute from narrowly elliptic or oblong to linear-oblanceolate with broader, thinner pale borders. Pappus bristles of mature achenes of more or less equal lengths, 4–5 mm long, white, fine and finely barbellate, without evident dilated tips. Ray florets 6–10, carpellate, corolla tube ca. 3 mm long, ca. as long as pappus, blade mostly narrowly elliptic, 3–4 mm long, yellow, stigma branches to ca. 1 mm long, dull brown, mature achenes cylindric to somewhat elliptic 2–3.5 mm long. Disc florets 11–16, perfect, corolla at anthesis ca. 6 mm, dull yellow, tube ca. 3 mm, throat with 5 divergent, narrowly triangular lobes ca. 2 mm; staminal ring ca. 2.5 mm long; stylar cylinder at anthesis 4–4.5 mm, stigma branches barely divaricate, ca. 1.5 mm. Mature achenes cylindric to somewhat compressed, 3–4

mm long, typically 5-ribbed, glabrous, abruptly narrowed to a short "neck" surmounted by narrow, brownish pappus disc.

DISCUSSION

Following Nesom's (1993) taxonomic alignment of *Solidago* L., we find that *S. arenicola* is part of section *Solidago*; however, it is unclear as to which subsection the new species should be placed, it having affinities for species in both *Solidago* and *Albigula* (Raf.) Nesom. Within the subsection *Solidago*, a species complex, loosely referred to as the "Simplex Group," seems to share similar morphologies with *S. arenicola* (Semple per. com.). The Simplex group is currently thought to be composed of three species which include *S. plumosa* Small, a distinct rarity known only from along the Yadkin River in North Carolina, *S. simplex* Kunth, a more complex and widespread set of morphologies, transcontinental and essentially northern but with one subspecies from the rocky banks of the Potomac River in eastern Virginia [ssp. *randii* (Porter) Ringius var. *racemosa* (Greene) Ringius] and *S. spathulata* DC, which is of dune areas restricted to California and Oregon (Cronquist 1980; Cronquist 1994; Hitchcock & Cronquist 1973). The hypothesized relationship with the Simplex Group and *S. arenicola* is based on a suite of characters that *S. arenicola* shares with these three species, including caudiciform rhizomes, basally disposed, spathulate or oblanceolate, glabrous leaves, racemose or thrysoid-paniculate inflorescences that lack recurved-secund branching, heads turbinate/campanulate with 3–4 seriate phyllaries, ray florets 6–10 per head, and achenes up to 3 mm or more long. Of the subsection *Albigula*, which includes several species found in the southeastern U.S., only *S. erecta* Pursh could be considered close enough to *S. arenicola* morphologically to cause confusion about their identity. The wide-ranging *S. erecta* is known to occur from coastal Massachusetts and New Jersey, west to Indiana and south to northeastern Mississippi, central Alabama, and Georgia. In addition to the characters mentioned above associated with the Simplex Group, which apply here as well, *S. erecta* and *S. arenicola* also sometimes share almost indistinguishable foliage (stem leaves average larger in length and width in *S. erecta*), as well as very similar achene shape. (Cronquist 1980; Small 1933).

Differences that help distinguish the new species from similar species of *Solidago* that are known to occur in the southeastern U.S. are detailed in the key below:

1. Achene surface persistently short-hairy _____ **S. simplex**
1. Achene surface glabrous.
   2. Inflorescence axis and branches glabrous; achenes 2–3 mm long _____ **S. plumosa**
   2. Inflorescence axis and branches pubescent; achenes 3–4 mm long.
      3. Number of heads per stem usually more than 40, involucres 4–6.5 mm high, disc flowers usually 6–10 per head, disc corollas ca. 4 mm long _____ **S. erecta**

3. Number of heads per stem usually less than 30, involucres 7–9.5 mm high, disc flowers usually 12–16 per head, disc corol as ca. 6 mm long _____ **S. arenicola**

ACKNOWLEDGMENTS

We are indebted to John Semple for his continued communication and valuable advice over the course of this project. We are also extremely appreciative of Laurel Hodges who aided in the translation of the English abstract to Spanish. We would like to thank Robert Haynes and Steve Ginzbarg who were very supportive and helpful during this project. We would also like to thank Guy Nesom and another anonymous reviewer whose suggestions proved to be extremely helpful in improving the quality of this paper.

ABSTRACT

Solidago faucibus, sp. nov., is described from two disjunct areas of the Appalachian Mountains: South Carolina and a contiguous area of Kentucky, Tennessee, Virginia, and West Virginia. The species is a decaploid ($2n = 90$) and has its affinities with the *Solidago arguta* group. It is distinctive in its extremely large leaves, especially on basal off-shoots, generally shorter inflorescence branches, large capitulae, uniformly pubescent achenes, and in forming large clonal (few-flowering) patches. Population variation, distribution, and habitat are discussed.

RESUMEN

Solidago faucibus, sp. nov., se describe de dos áreas disyuntas de los Montes Appalaches en Carolina del Sur y un área contigua de Kentucky, Tennessee, Virginia, y West Virginia. La especie es un decaploide ($2n = 90$) y tiene afinidades con el grupo de *Solidago arguta*. Se diferencia por sus hojas extremadamente grandes, especialmente en los renuevos basales, generalmente ramas de la inflorescencia más cortas, capítulos grandes, aquenios uniformemente pubescentes, y en formar grandes céspedes clonales (que producen pocas flores). Se discute la variación poblacional, distribución, y hábitat.

INTRODUCTION

The existence of an anomalous goldenrod became known to the first author while doing fieldwork in The Breaks of Russell Fork in Buchanan and Dickenson Counties, Virginia, in late summer of 1982. The plant was notable for its large size, especially its basal off-shoot (rosette) leaves. Initially there was uncertainty regarding its proper status, as there was some thought of its possibly being a hybrid (A. Cronquist, pers. comm.). Over the next 10 years, additional populations of the plant were found in eastern Kentucky, southern West Virginia, other locations in southwestern Virginia, and most recently in Tennessee. Notable in this regard, the populations showed a definite affinity for specific habitat parameters. That the plant recurs in the landscape over a fairly large geographic area and occupies a specific habitat type argues for its recognition as a species. It is herewith described as new.

SIDA 20(4): 1595–1603. 2003

Solidago faucibus Wieboldt, sp. nov. (**Fig. 1**). TYPE: UNITED STATES. VIRGINIA. Lee Co.: dry hardwoods around top of N-facing limestone cliff on Powell River, just above Wilder Bend at river mile 135.6, SW of Jonesville, 24 Sep 1992, *T.F. Wieboldt 8429* (HOLOTYPE: VPI; ISOTYPES: NY, US, VDB, WAT).

Ex affinitate *Solidago arguta* Aiton, sed foliis basalibus laminis truncatis basaliter ad *S. harrisii* Steele similis, differt ramis floriferis brevibus, capitulis secundis inconspicuo, phyllaria nervis utroque costae latere, marginibus parallelis, apicibus rotundatis sparse ciliatis. Habitat in sylvis humidas apprime faucibus.

Herbaceous perennial from a branching caudex, generally producing 1–2 (several) lateral off-shoots terminated by a cluster of large rosette leaves. **Stems** erect, solitary, terete, 3–6 mm wide at base, 7.5–15 dm tall, glabrous below the inflorescence (and usually into the lower portion of the inflorescence). **Leaves** dull green above, pale below, the veinlets forming distinct areolae. Basal and lower cauline leaves with a pair of primary lateral veins arising 2–3 cm above the base of the blade and running most of its length. Basal offshoot leaves very large, petiolate, abruptly tapering to a winged petiole 10–20 cm long; blade ovate 12–22 cm long, 7–15 cm wide, broadly tapering to truncate or slightly cordate (rarely) base, apices acute, margin singly or doubly serrate with teeth 1–3(–6) mm. Lower stem leaves largest, slightly smaller than rosette leaves, petiolate, abruptly tapering to a winged petiole, ovate, progressively reduced upwards and becoming sessile, glabrous abaxially, scabrous-hispidulous adaxially at least along margins, serrate with teeth 1–3 mm long, 4–7 per cm. **Inflorescence** variable, mostly narrow and elongate, consisting of a slightly arching main axis 12–60 cm long with axillary and terminal racemiform branches 2.5–7(–13) cm, averaging about 4 cm, or, in sunny situations, wider and compounded, consisting of multiple inflorescence branches with short secondary racemes, leafy bracted below, branches and peduncles pubescent with short, stiff, upwardly curved, multicellular hairs. **Heads** large, few to many, inconspicuously secund on longer branches, appearing fasciculate on shorter branches, peduncles 2–5 mm (longer on South Carolina plants, 4–10(–13) mm). **Involucres** 4.5–7 mm. **Phyllaries** 10–18, in 4–6 series; median phyllaries averaging 3–4.5 mm long by 1–1.4 mm wide, lanceolate, broadly acute to obtuse, glabrous except for fimbriate-ciliate margins towards tip, ascending; midvein heavy and dark, slightly resinous and raised in distal portion, a pair of lateral veins commonly present, sometimes evident as interrupted lines, or occasionally only as a short resinous line in the distal half. **Ray florets** 4–6; strap 2.2–3.5 mm, 0.8–1.7 mm wide. **Disc florets** 5–7(–11), corollas 4.0–5.6 mm, lobes 1.6–2.5 mm, stigmatic lobes 1–1.3 mm, anthers 2–2.9 mm. **Achenes** 2.5–3.2 mm long, short pubescent at least on upper half, somewhat variable within populations; pappus bristles 3–4.7 mm. Chromosome number $2n = 90$.

Etymology.—The species epithet *faucibus* is taken from the phrase "*in faucibus crescens*" meaning "growing in the gorges" (Stearn 1983). The common name "Gorge Goldenrod" is suggested in reference to its preferred habitat.

FIG. 1. *Solidago faucibus* Wieboldt based on collections from the type station, Lee County, Virginia. Rootstock with basal leaves and offshoot, inflorescence, flower head (side view), median phyllary, achene with pappus.

Additional specimens examined: **KENTUCKY: Breathitt Co.:** Robinson Forest, 9 Oct 1982, *W. Meijer s.n.* (KY). **Clay Co.:** base of E-facing slope with much *Laportea canadensis*, Redbird River, 0.1 mi N of Kates Creek, Daniel Boone National Forest, Creekville Quad., 37°2'12"N, 83°32'25"W, 30 Jul 1992, *Allen C. Risk 6330* (MDKY). **Leslie Co.:** Red Bird River, mesic hardwoods at toe of SW-facing slope at mouth of Bowen Creek, 1.5 km SE of Creekville, 24 Sep 1992, *T.F. Wieboldt 8422, J. Campbell, and D. Taylor* (VPI); abandoned picnic area, hemlock woods, US-421 S of Stinnel, just S of where highway crosses the river, 14 Sep 1991, *J.C. Semple 9619 and B.A. Suripto* (WAT); moist soil, shaded lower slope in south flowing ravine, 1.5 mi SE of F.S. Rd. 1530 from junction KY 66 and F.S. Rd. 1530 in Bowen Creek, 17 Sep 1993, *James D. Kiser 371* (MDKY); low steep banks near gullies, along Kentucky River opposite Frontier Nursing Services, 9 May 1990, *J. Campbell s.n.* (KY); same locality, Jul 1991 & 6 Sep 1991, *J. Campbell s.n.* (KY). **Letcher Co.:** wooded ravine and hillsides near big Everidge entrance, gravelly road bank, full sun, Lilly Cornett Woods State Preserve, 4 Oct 1974, *J. Stuart Lassetter 2361* (EKY). **Owsley Co.:** slopes along Brushy Creek, Sturgeon, 22 May 1990, *J. Campbell s.n.* (KY). **SOUTH CAROLINA: Pickens Co.:** SR-39-98, E of US-178, 17 Oct 1981, *Semple and Chmielewski 6170* (WAT); in rich deciduous woodlands with circumneutral or ultramafic soils on slopes above Eastatoe Creek, 0.8 km E of bridge on St. Rt. 143 (Roy F. Jones Hwy), 8 Sep 2001, *P.D. McMillan 5866* (CLEM); dry, medium-aged successional woodland S of Roy F. Jones Hwy, 1.1 km W of jct. Hwy 11, 2 Oct 2002, *T.F. Wieboldt 11083* (VPI). **TENNESSEE: Campbell Co.:** mesic hardwoods dominated by sugar maple, toe of N-facing slope above Hwy 25W where Clear Fork cuts through Pine Mountain, 4 mi W of Jellico, 18 Jun 2003, *T.F. Wieboldt 11206* (VPI); **Hancock Co.:** 02-302, Short Mt. Rd. 0.1-0.2 mi above church, 7 Oct 2002, *H.R. DeSelm s.n.* (TENN). **VIRGINIA: Buchanan Co.:** Breaks Interstate Park, rich hardwoods along Grassy Creek, Oct 1982, *F. Levy s.n.* (VPI); base of mesic hardwood slope, Knox Creek 4.6 km NW of Hurley, 14 Sep 1991, *T.F. Wieboldt 7913 and D.W. Ogle* (VPI). **Dickenson Co.:** Breaks Interstate Park, mesic, rich hardwoods along Russell Fork just above Garden Hole parking, 25 Aug 1982, *T.F. Wieboldt 4483, A.B. Davenport, F. Levy, M. Medley, and M. Palmer* (VPI); same locality, 22 Sep 1992, *T.F. Wieboldt 8417* (VPI). **Giles Co.:** limestone bottomland, deep woods, Rt. 649 N of Glen Lyn, 16 Aug 1973, *L.J. Uttal 10217* (VPI). **Lee Co.:** ledges, summit, and adj. woods around high, N-facing limestone cliff, Powell River just above Wilder Bend, 6.8 km SW of Jonesville, 24 Sep 1985, *T.F. Wieboldt 5893* (VPI), (type station). **Scott Co.:** seepage area near base of high, E-facing cliff along Guest River 0.15 km above confluence with Clinch River, 8.5 km SE of Coeburn, 9 Aug 1985, *T.F. Wieboldt 5825 and A.B. Wieboldt* (VPI). **Tazewell Co.:** oak-dominated mixed hardwoods on narrow, rocky (limestone) ridgeline between Clinch River and Indian Creek at Cedar Bluff, 6 Aug 1997, *T.F. Wieboldt 9769* (VPI). **Wise Co.:** Guest River gorge, 14 Sep 1984, *D.W. Ogle s.n.* (VPI). **WEST VIRGINIA: McDowell Co.:** very dry hillside, Route 52, Keystone, 9 Sep 1962, *F. Rusinke s.n.* (WVU). **Mercer Co.:** mesic stream bottom woods from toe of slope to rocky riverbank, 0.75 mi below Eads Mill along Bluestone River, 2 Oct 1984, *T.F. Wieboldt 5352 and C. Douglas* (VPI); near base of NE-facing outcrops, mesic hardwoods just above road along New River 0.25 mi W of Virginia line, 30 Aug 1985, *T.F. Wieboldt 5945* (VPI). Duplicate specimens are to be distributed.

The range of *Solidago faucibus* coincides closely with that of the Appalachian coalfield region, which may account, in part, for its having gone unrecognized for so long. This rugged terrain of narrow winding valleys cut into the Appalachian and Cumberland Plateaus is, with few exceptions, poorly botanized due to difficulties of travel and remoteness from population centers.

Solidago faucibus appears to have affinities to *Solidago arguta* Aiton. The *Solidago arguta* group has been variously defined by different authors (see Morton 1973, and references therein). Shared characters with the core members of the group include having the basal leaves largest and progressively reduced upwards, secund flowering branches, glabrous round stems (below inflorescence),

hirtellous pedicels and inflorescence branches, and glabrous abaxial leaf surfaces (Small 1933). The confusion and difficulties in the group are amply described by Morton (1973). As a direct result of these concerns, considerable hesitancy has been exercised in naming this species. The species bears a close resemblance to *Solidago arguta* var. *harrisii* (Steele) Cronq. In fact, the earliest known collection of the species is that of E.L. Braun who reported it as *Solidago harrisii* (Braun 1943; Campbell 1993). *Solidago harrisii* was described by Edward S. Steele (1911) from the shale barrens of the central Appalachians. It was subsequently considered part of the endemic flora of these unique habitats (Keener 1983, but see also Braunsweig et al. 1999). Whether treated as a species or a variety of *S. arguta*, the taxon has subsequently been found to occur with high fidelity in association with limestone cliffs over a considerably broader region. While Braun's plant proves to be *S. faucibus*, true *S. arguta* var. *harrisii* has since been found in remote areas of eastern Kentucky (J. Campbell, pers. comm.).

Cytology.—Chromosome counts of $2n = 90$ have been determined from three locations. First, Semple et al. (1993) reported a chromosome count of $2n = 90$ for *S.* aff. *flexicaulis* L. from Leslie County, KY. *Solidago flexicaulis* was otherwise known to be tetraploid or hexaploid (Semple et al. 1984). Leslie County, KY, is one of the areas where multiple populations of *S. faucibus* are known; the voucher (*Semple & Suripto 9619* WAT) is *S. faucibus*. Second, Semple et al. (1984) reported $2n =$ ca. 96 for *S.* cf. *glomerata* Michaux from Pickens Co., South Carolina. The voucher (*Semple & Chmielewski 6170* WAT) was reexamined and also found to be a plant of *S. faucibus*. Review of notes indicate the count was redone later and confirmed to be $2n = 90$, but not yet corrected in the literature. Third, when plants of an *arguta* type were found in South Carolina by Patrick McMillan, photos were sent to the first author to see if they might be the as yet unnamed taxon. After seeing the plants in the field in the fall of 2002, the first author confirmed that they were the same despite a few minor differences. Live plants were sent to the second author who determined that they also were $2n = 90$. In *Solidago*, chromosome numbers of $2n = 90$ are otherwise known only for *S. lancifolia* Torr. & A. Gray, from which *S. faucibus* is readily distinguished (*S.* subsect. *Glomeruliflorae*; Rachel Cook and J.C. Semple, pers. comm.).

DISCUSSION

The most striking feature of *Solidago faucibus* is its large rosette leaves which often form large patches (clones?) with few flowering stems. In addition, several diagnostic characters serve to distinguish *S. faucibus* from members of the *S. arguta* group. Inflorescence shape is of critical importance in goldenrod taxonomy. The disposition of heads along the upper side of inflorescence branches is made conspicuous in *S. arguta* by the widely spreading branches which are

often naked or few-flowered proximally. In *S. faucibus*, the branches of typical woodland plants are short, floriferous to the leaf axil, and inconspicuously secund, often suggesting an elongated axillary thyrse. The secund nature of the inflorescence may be obscured even more in pressed specimens. Often, only the longest (basal-most) branches display the secund condition. Given an abundance of sunlight in disturbed areas and along woods roads, primary branches may be more elongate with secondary branching being similarly thyrsoid to short racemose. It is these open-grown plants with their more open architecture that somewhat disguises their identity since their primary branches may be clearly secund. Nevertheless, the basal off-shoots and involucral bracts readily identify them.

The involucral bracts of *Solidago faucibus* provide additional key characters which are especially helpful in distinguishing it from *S. arguta* var. *harrisii*. Median involucral bracts clearly show the presence of a lateral vein on either side of the midvein. It is sometimes discontinuous and may show more clearly in the distal half. The median phyllaries are parallel-sided with a rounded, sparsely ciliate tip. These two features clearly differentiate it from *S. arguta* var. *harrisii*, which has only a single midvein and phyllaries that taper most of their length with barely discernible marginal hairs at the tip. Although leaf shape of *S. arguta* var. *harrisii* is nearly identical, that variety's widely spreading inflorescence normally identifies it without having to resort to involucral characters.

The multinerved condition of the phyllaries does not fit Nesom's characterization of *Solidago* subsect. and ser. *Argutae* (Mackenzie in Small) Nesom (Nesom 1993). However, multinerved phyllaries occur in other species in other subsections as well: *S. roanensis* Porter in subsect. *Albigulae* (Raf.) Nesom; *S. glomerata* and *S. lancifolia* in subsect. *Glomeruliflorae* (Torr. & A. Gray) Nesom; the well known oligoneurate species of sect. *Corymbosae* Torr. & A. Gray (the genus *Oligoneuron* in Nesom 1993, 2000).

Due to its abruptly narrowed leaf bases and more constricted inflorescence compared with typical *S. arguta*, the new species can be confused with *S. flexicaulis*. The large size is an important consideration because herbarium specimens may lack the lower stem leaves which are crucial in aligning it with *S. arguta* rather than *Solidago* subsect. *Glomeruliflorae*. *Solidago flexicaulis*, as well as other members of its subsection, has its largest leaves near mid-stem or even closer to the inflorescence. Lower stem leaves are generally absent at flowering time.

Typical *Solidago arguta* is found commonly throughout the region in drier sites. On rare occasions, it is found within a few feet of *Solidago faucibus*, in which case the two are readily distinguishable with no intermediates being found. Any intermediates would be cytologically very distinct being either $2n = 54 (= 9 + 45)$ or $2n = 63 (= 18 + 45)$.

Population variation.—Apart from the unifying characters discussed above, *Solidago faucibus* displays considerable population variation in several morphological characters. These include leaf vestiture, leaf toothing, inflorescence branch length, involucre length, peduncle length, and disposition of capitulae (secund or not). A geographical trend is noted in South Carolina plants although not all plants display it to the same degree.

Leaves are sparsely scabrous-hirsutulous above. The zone of hairs is typically marginal but varies in width up to about 1 cm wide, especially toward the leaf tip. Scabrous hairs sometime occur more widely on veins. South Carolina plants are scabrous-hirsutulous over most or all of their upper surfaces. Marginal teeth of basal and rosette leaves vary from single, low (1 mm) serrations to doubly serrate with jagged teeth (3 mm). Individual populations are quite uniform, however. Inflorescence branch length is quite variable and appears to be partly environmentally controlled. The longest branches occur on South Carolina plants, which display a general tendency toward elongation of parts. Peduncles are longer (4-10 mm vs. 2–4 mm), involucres average longer, although the ranges are only slightly skewed toward the long end of the range, and stigmas and anthers are longer. Plants from The Breaks (Buchanan and Dickenson Counties, Va.) with uniformly tight inflorescence branches, when transplanted to full sun, produced elongate primary branches with short, secund secondary branching. These populations also have the least coarsely toothed leaves and leaf blades with noticeably longer length:width ratios. As noted above, heads on the short inflorescence branches are inconspicuously secund in most populations. This condition is barely noticeable in the Bluestone River population (Mercer Co., W. Va.), which otherwise fits well into the species concept. South Carolina plants are similarly thyrse-like with the slight secund condition being further obscured by the longer peduncles. South Carolina populations seem to flower very infrequently, however, so relatively few flowering stems have been observed. The rosette leaves of South Carolina plants are more truncate to slightly cordate at the basal angle, and basal rosettes are produced on longer off-shoots than the more northern populations.

The high polyploid condition may be a factor in population variation. Multiple copies of the genome could provide an inherent variability with different phenotypic expressions being favored in different populations. It is not known whether the 10*x* chromosome number is the result of sequential autopolyploid events with divergence from a single species of *Argutae*, the result of allopolyploid events involving several species of *Argutae*, or the result of a combination of autopolyploidy and allopolyploidy. If allopolyploidy were involved, then *S. faucibus* would likely include greater genetic variation.

Habitat.—*Solidago faucibus* occupies the most mesic habitats of any species in the *S. arguta* group. It is especially tolerant of deep shade, not uncom-

monly growing under *Tsuga canadensis* (L.) Carr., eastern hemlock. Nevertheless, it is also tolerant of a wide range of moisture conditions and bedrock types. The species most often occurs along rivers and major streams where they are entrenched in the surrounding landscape. In the Cumberland and Appalachian Plateaus and the Ridge and Valley Province, gorge-like conditions frequently occur where streams cut through more resistant rocks. It is near the base of these steep, often rocky, slopes that *S. faucibus* is most often found, being conspicuously absent from the gentler terrain of intervening areas. In this rugged landscape, forests are frequently intact and typically support a very mesic, mixed hardwood association. In limestone districts, the species may occupy considerably more open cliff sites.

KEY TO SPECIES OF *SOLIDAGO* SER. *ARGUTAE*

1. Leaves minutely scabrous, puberulent or short villous, blades attenuate at base.
   2. Leaves scabrous on upper surface, the hairs very short and with swollen bases; bogs, swamps, and seepage wetlands _____ **S. patula**
   2. Leaves soft villose or puberulent.
      3. Rays usually 7–12; leaves moderately to densely short villose; spring blooming; coastal plain of N.C., S.C. _____ **S. verna**
      3. Rays none, rarely 1-2; leaves densely and finely puberulent; fall blooming; open woods, coastal plain and piedmont, S.C. to Ala. (possibly Miss.) _____ **S. brachyphylla**
1. Leaves glabrous or nearly so, or if scabrous above, the blades abruptly contracted or truncate at base.
   4. Phyllaries striate, several veins enlarged, involucres 4.5–7 mm; Va., W.Va., Ky., Tenn., S.C. _____ **S. faucibus**
   4. Phyllaries not striate, only main vein enlarged (very rarely more striate in *S. arguta*).
      5. Plants without slender stoloniferous rhizomes _____ **S. arguta** (including *S. harrisii*)
      5. Plants with slender stoloniferous rhizomes in addition to main more deeply situated rhizome or caudex.
         6. Lower leaves elliptic to obovate (ovate), acute, with obtuse to attenuate base; upper stem leaves quickly reduced and ascending to appressed _____ **S. ludoviciana**
         6. Lower leaves mostly ovate, acute to acuminate, with truncate to obtuse base; upper stem leaves gradually reduced, rarely appressed _____ **S. tarda**

ACKNOWLEDGMENTS

The first author would like to thank his wife, Ali Wieboldt, for her artistic talents in creating Figure 1. Thanks also to many botanists, Foster Levy, Julian Campbell, Max Medley, in particular, who have known the plant, encouraged the work, and extended unlimited grace in waiting for it to be named. Thanks to Patrick McMillan for sharing his discovery on the plants in South Carolina, and sharing a day in the field. We thank curators at CLEM, EKU, KY, MDKY, MUHW, NCU, and WVU for making specimens available to the first author. Appreciation is extended to Guy Nesom and Alan Weakley for their critique

and helpful suggestions concerning the draft manuscript. Duncan Porter and Andrew Becker helped resolve questions about the proper form of the species epithet.

BOOK NOTICES

TIMBER PRESS

Horticulture/Gardening

JOHN C. MANNING, PETER GOLDBLATT, and DEE SNIJMAN. 2002. **The Color Encyclopedia of Cape Bulbs.** (ISBN 0-88192-547-0, hbk.). Timber Press, Inc. 133 S.W. Second Ave, Suite 450, Portland, OR 97204-3527, U.S.A. (Orders: www.timberpress.com, mail@timberpress.com, 503-227-2878, 1-800-327-5680, 503-227-3070 fax). $59.95, 486 pp., 611 color photos, 2 color maps, 2 tables, 8 1/2 × 11".

The title just about says it all. The book is filled with excellent color photographs, it is encyclopedic (nearly 1200 species), and it is all about bulbous and beautiful plants that grow in the Cape Floral Region at the southern tip of Africa. Included at the end is a Conversion Table, Specialist Suppliers, Glossary, References, Index of Synonyms, and an Index of Common Names. Well done thou good and faithful servants! See notice (Sida 19(2), 2000) on a previous book by two of the authors (Goldblatt and Manning) *Wildflowers of the Fairest Cape*.

DAVID MORE and JOHN WHITE. 2002. **The Illustrated Encyclopedia of Trees.** (ISBN 0-88192-520-9, hbk.). Timber Press, Inc. 133 S.W. Second Ave, Suite 450, Portland, OR 97204-3527, U.S.A. (Orders: www.timberpress.com, mail@timberpress.com, 503-227-2878, 1-800-327-5680, 503-227-3070 fax). $79.95, 800 pp., 4500 color plates (watercolors), 7 1/4 × 10 3/8".

Even though the trees selected and illustrated are commonly cultivated in England and continental Europe, many are found here in American gardens and many are native to North America. This is a beautiful work that took 12 years compile. Deciduous trees are illustrated with both a summer painting in full leaf and a winter silhouette. Both deciduous and evergreen trees are illustrated as well with a close-up artwork detailing leaves or needles, bark, blossoms, fruit, nuts, or cones. More than 1800 species and cultivars are detailed in this beautifully done work.

ALLAN M. ARMITAGE and JUDY M. LAUSHMAN. 2003. **Specialty Cut Flowers: The Production of Annuals, Perennials, Bulbs, and Woody Plants for Fresh and Dried Cut Flowers. Second Edition, Revised and Enlarged.** (ISBN 0-88192-579-9, hbk.). Timber Press, Inc. 133 S.W. Second Ave, Suite 450, Portland, OR 97204-3527, U.S.A. (Orders: www.timberpress.com, mail@timberpress.com, 503-227-2878, 1-800-327-5680, 503-227-3070 fax). $39.95, 636 pp., 100 color photos, 84 line drawings, 1 map, 6 × 9".

Contents.—Preface, Acknowledgments, Introduction, Postharvest Care, Drying and Preserving, Cut Flowers: *Achillea* to *Zinnia*, References, Appendix I: Stage of Harvest; Appendix II: Additional Plants Suitable for Cut Flower Production; Appendix III: Useful Conversions; U.S. Department of Agriculture Hardiness Zone Map, Index of Botanical Names, and Index of Common Names.

NEW NAMES AND COMBINATIONS IN GOLDENRODS, *SOLIDAGO* (ASTERACEAE: ASTEREAE)

John C. Semple

Department of Biology
University of Waterloo
Waterloo, Ontario, CANADA N2L 3G1

ABSTRACT

The following new names and combinations in *Solidago* are proposed: ***Solidago*** subsect. ***Multiradiatae***, ***Solidago*** subsect. ***Humiles***, ***Solidago*** ser. ***Auriculatae***, ***Solidago*** ser. ***Odorae***, ***Solidago*** ser. ***Drummondiani***, ***S. altissima*** subsp. ***gilvocanescens***, ***S. kralii***, ***S. lepida*** subsp. ***fallax***, ***S. lepida*** var. ***salebrosa***, ***S. odora*** subsp. ***chapmanii***, ***S. patula*** subsp. ***strictula***, ***S. puberula*** subsp. ***pulverulenta***, ***S. rugosa*** var. ***cronquistiana***, ***S. sempervirens*** subsp. ***azorica***, ***S. sempervirens*** subsp. ***mexicana***, ***S. speciosa*** subsp. ***pallida***, ***S. stricta*** subsp. ***gracillima***, ***S. velutina*** subsp. ***californica***, and ***S. velutina*** subsp. ***sparsiflora***.

RESUMEN

Se proponen los siguientes nombres y combinaciones nuevos en *Solidago*: ***Solidago*** subsect. ***Multiradiatae***, ***Solidago*** subsect. ***Humiles***, ***Solidago*** ser. ***Auriculatae***, ***Solidago*** ser. ***Odorae***, ***Solidago*** ser. ***Drummondiani***, ***S. altissima*** subsp. ***gilvocanescens***, ***S. kralii***, ***S. lepida*** subsp. ***fallax***, ***S. lepida*** var. ***salebrosa***, ***S. odora*** subsp. ***chapmanii***, ***S. patula*** subsp. ***strictula***, ***S. puberula*** subsp. ***pulverulenta***, ***S. rugosa*** var. ***cronquistiana***, ***S. sempervirens*** subsp. ***azorica***, ***S. sempervirens*** subsp. ***mexicana***, ***S. speciosa*** subsp. ***pallida***, ***S. stricta*** subsp. ***gracillima***, ***S. velutina*** subsp. ***californica***, y ***S. velutina*** subsp. ***sparsiflora***.

The following new names and combinations were determined to be needed during work to prepare the treatment of *Solidago* for *Flora North America* (Semple & Cook, submitted). Ten of the new combinations treat taxa as subspecies that usually have been recognized as varieties. The definitions of the ranks follow Semple (1974). In each case, the subspecies is morphologically distinct and has a distribution that is nearly allopatric from the other subspecies within the respective species. Intermediates between the subspecies occur in the areas of sympatry. Ranges of varieties overlap considerably, with pure and intermediate populations occurring intermixed within the range of the variety. Hamilton and Reichard (1992) noted inconsistencies in application of the ranks to taxon, and some of the combinations proposed here correct such inconsistencies within *Solidago* in North America. Subsection and series names are proposed to fit my opinions on how species should be grouped within the genus; a full infrageneric nomenclature is included in Semple and Cook (submitted).

Solidago subsect. **Multiradiatae** (Juz.) Semple, comb. nov. BASIONYM: *Solidago* ser. *Multiradiatae* Juz., Fl. U.R.S.S. 25: 47. 1959. TYPE: *Solidago multiradiata* L.

Solidago subsect. **Humiles** (Rydb.) Semple, comb. et stat. nov. BASIONYM: *Solidago* (sp.-group) *Humiles* Rydb., Fl. Rocky Mts. 868. 1917. TYPE: *Solidago humilis* A. Gray (1884), non Pursh (1814). [= *S. simplex* Kunth]

Solidago ser. **Auriculatae** Semple, ser. nov. TYPE: *Solidago auriculata* Shuttlew. ex S.F. Blake

Solidagini subsect. *Argutae* (Mackenzie) Nesom accedens sed foliis auriculatissimis differt.

The leaves are distinctly auriculate clasping. The basal leaves are largest and petiolate like other *Argutae*.

Solidago ser. **Odorae** (Mackenzie in Small) Semple, comb. et stat. nov. BASIONYM: *Solidago* (sp.-group) *Odorae* Mackenzie in Small, Man. SE. Fl. 1345, 1346. 1933. *Solidago* subsect. *Odorae* (Mackenzie in Small) Nesom, Phytologia 75:10. 1993. TYPE: *Solidago odora* Aiton.

Solidago ser. **Drummondiani** Semple, ser. nov. TYPE: *Solidago drummondii* Torr. & A. Gray.

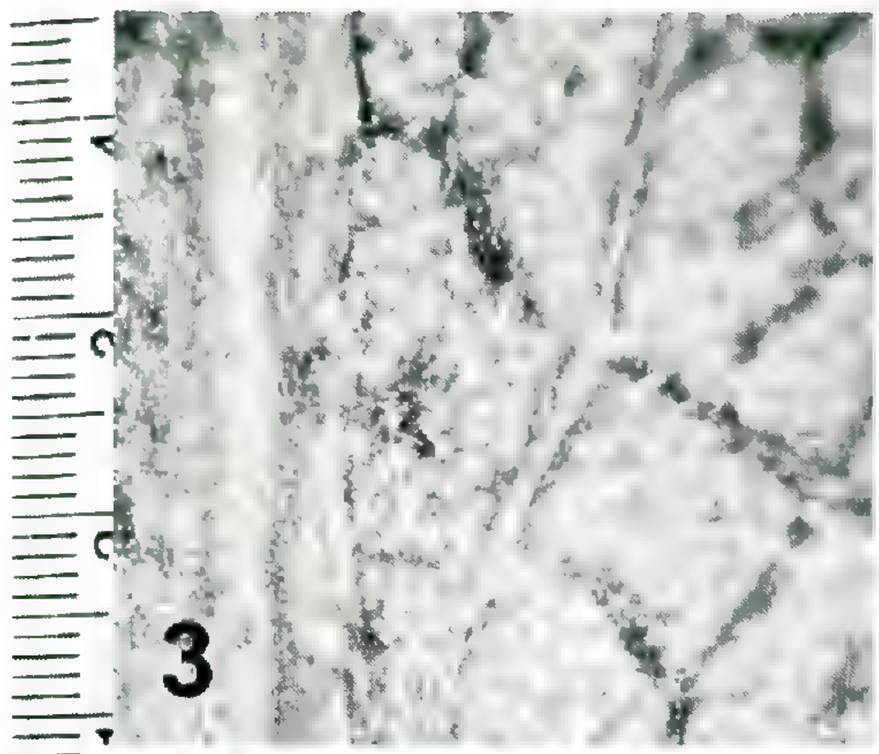
Solidagini ser. *Venosae* G. Don accedens sed foliis caulis ovatis triplinervis differt.

Lower mid stem leaves ovate, serrate and with two, large, lower lateral veins (triple-nerved) as well as additional less enlarged upper lateral veins

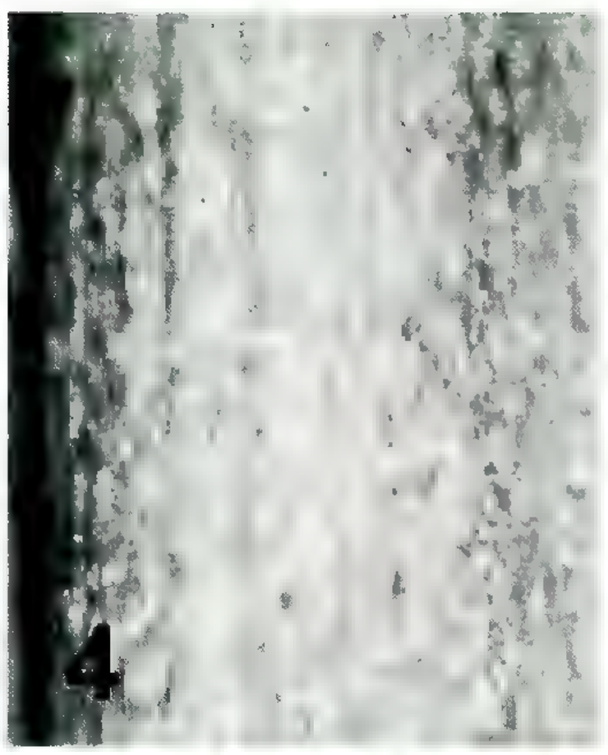
Solidago altissima L. subsp. **gilvocanescens** (Rydb.) J.C. Semple, comb. et stat. nov. BASIONYM: *Solidago canadensis* L. var. *gilvocanescens* Rydb., Contr. U.S. Natl. Herb. 3:162. 1895. *Solidago gilvocanescens* (Rydb.) Smyth, Trans. Kansas Acad. Sci. 16:161. 1899. *Doria gilvocanescens* (Rydb.) Lunell, Amer. Midl. Naturalist 5:43. 1917. *Solidago canadensis* L. ssp. *gilvocanescens* (Rydb.) Löve & Löve, Taxon 31:358. 1982. *Solidago altissima* L. var. *gilvocanescens* (Rydb.) Semple, Phytologia 58:430. 1985. TYPE: U.S.A. NEBRASKA. Hooker Co.: Cody's Lakes at the head of the Dismal R, sandy soil, 10 Aug 1893, *Rydberg 1662* (HOLOTYPE: US, photo!; ISOTYPES: GH!, NY2, photos!).

Subspecies *gilvocanescens* includes diploids and tetraploids of *S. altissima* found across the Great Plains from southern Canada to Texas. Subspecies *altissima* includes hexaploids throughout its range in eastern North America from the edge of the Great Plains eastward from Nova Scotia to northern Ontario and eastern Manitoba south to northern Florida and eastern Texas; a few tetraploids are known from Arkansas and Tennessee. The subspecies differ in head and floret size and are difficult to distinguish where the two ranges overlap.

Solidago kralii Semple, sp. nov. (**Figs. 1–11**). TYPE: U.S.A. GEORGIA. Pulaski Co.: ca. 1–1.5 mi S of jct. US-341 and GA-230 at Hartford, longleaf pine scrub hills, 10 Aug 1975, *R. Kral 56345* (HOLOTYPE: VDB!; ISOTYPE: MO!).



Solidagini plumosa Small accedens sed capitulescentiis viscidis resinosisimis differt.



Herbaceous perennials from creeping rhizomes. Stems 6.5–12 dm tall, glabrous to sparsely strigulose in capitulescence, often copiously viscid resinous in capitulescence. Basal leaves petiolate, blade gradually tapering to winged petiole, oblanceolate, (2.5–)10–20 cm long, (4–)15–28 mm wide, main vein prominent,

FIG. 1. Holotype of *Solidago kralii, R. Kral 56345* (VDB).

FIGS. 2–8. Details of the morphology of *Solidago kralii*. **2.** Mid stem leaf, scale bar in cm. **3.** Mid stem leaf surface detail by mid vein. **4.** Stem. **5.** Portion of capitulescence. **6.** Capitulum. **7.** Involucre. **8.** Mature cypsela, glabrous body, scale bar = 1 mm.

FIGS. 9–11. Ecology of *Solidago kralii*. **9.** Road margin habitat through sand hill; Ben Hill Co., Georgia (*Semple & Semple 11216*). **10.** Habit of 1 m tall robust individual; Richmond Co., Georgia *(Semple & Semple 11217*). **11.** Large bee visitor on flowering head; Pulaski Co., Georgia *(Semple & Semple 11208*).

membranous, glabrous, viscid, margins shallowly serrate apically, teeth less than 1 mm long, finely ciliate; rosettes present at flowering, forming at the ends of elongated rhizomes, first leaves produced the smallest. Lower to mid stem leaves similar to basal to sessile and linear elliptic, quickly reduced, mid stem leaves 4–8 cm long, 6–9 mm wide, reduced upward, viscid, entire. Upper stem leaves sessile, linear elliptic to linear, 10–35 mm long, 1–3 mm wide, reduced into capitulescence, glabrous, viscid. Capitulescence narrowly thyrsiform

paniculiform, 9–30(–40) cm long, 4–7(–12) cm wide, longer branches ascending, 2–4(–15) cm long; heads 1–9(–15) per branch. Peduncles sparsely strigulose, somewhat to copiously resinous, naked below to bracteolate near heads, bracteoles usually 1–3. Involucres campanulate, 5–7 mm high. Phyllaries in 3–4 strongly graduated series, the outer ovate 1.5–2 mm long, middle ones 3–4 mm long, narrowly ovate, to 1.5 mm wide, inner linear lanceolate, apex obtuse, rounded to slightly cuspidate, ciliate, surfaces often copiously resinous, very sparsely finely strigose and obscured by exudate. Ray florets 3–5(–11), strap 2.5–3.5 mm long, 1–1.5 mm wide. Disc florets 10–16(–20), corolla 5–6 mm long, lobes 1–1.5(–1.8) mm long. Cypsellae fusiform to narrowly obconic, 3–5 mm long, 5–8 golden brown thin ribs darker than intercostal portions, glabrous; pappus bristles 4–5 mm long, sometimes strongly clavate. $2n = 18$.

Flowering August–September. Turkey oak and pine scrub sandhills; Ga., S.C.

Kral's Goldenrod is closely related to *S. simplex* Kunth, *S. plumosa* Small and *S. arenicola* Kral & Keener, the latter two and *S. kralii* possibly being divergent and isolated relicts of a common ancestor more widely distributed across the southeastern United States during late glacial times. *Solidago kralii* is often much more copiously viscid resinous then these other three species. The involucres of *S. arenicola* are much taller than those of *S. kralii* and *S. plumosa*. Recently made field collections of *S. kralii* tended to stick somewhat to the newsprint in which specimens were dried. *Solidago kralii* is nearly always found in full sun on sandhills (Fig. 9); the sites can be highly disturbed. Population sizes varied from one to several dozen or more individuals, the exact number not being determined during recent field observations. Individuals were observed in the field with more than three dozen robust shoots up to 1 m tall (Fig. 10). In general, plants of *S. arenicola* observed in the field in September 2003 were much shorter, had fewer shoots, and were only found in partially shaded sandy soils of river banks in northern Alabama. *Solidago plumosa* can be as tall as *S. kralii*, but it is known is only from the type location in Stanly Co., North Carolina on a very limited section of the rocky margins of the Yadkin River, a habitat observed in September 2003 that was, prior to dam construction, probably similar to the habitat of tetraploid *S. simplex* var. *racemosa* (E.L. Greene) Ringius along the Potomac River near the Great Falls of the Potomac in Maryland observed in 1984 (*Semple & Ringius 7663* WAT; Ringius and Semple 1987).

Chromosome counts for *S. kralii* determined from two locations were both were diploid: $2n = 18$, **U.S.A. Georgia. Pulaski Co.:** S of Hartford, GA-230 1 km SE of US-341/GA-27, 23 October 2001, *R. Cook et al. 701* (WAT; shoots well past blooming); $2n = 9_{II}$, **U.S.A. Georgia. Richmond Co.:** US-1, NE of Blythe, S of Ellis Pond, steep roadside embankment, sand hill, 7 Sep 2003, *J. Semple & B. Semple 11217* (WAT).

The species is named in honor of Dr. Robert Kral (VDB) who collected the specimens that first brought the species to my attention. He is well known for

his work on the flora of the southeastern United States over many years and for his numerous collections deposited in VDB and duplicates in many other herbaria in eastern North America.

Additional collections: **U.S.A. GEORGIA. Ben Hill Co.:** US-129 at S edge of Bowens Mill town limits, just N of GA-182, 7 Sep 2003, *J. Semple & B. Semple 11212* (WAT); S of Bowens Mill, US-129 0.4 km S of GA-182, 7 Sep 2003, *J. Semple & B. Semple 11216* (WAT); 8.2 mi N of Fitzgerald, sandhills by US-129, 25 Sep 1975, *Kral 56788* (MO, VDB). **Pulaski Co.:** W side of Hartford, US-341 0.9 km E of GA-26, just E of radio station, 7 Sep 2003, *J. Semple & B. Semple 11208* (WAT). **Richmond Co.:** Ft. Gordon Military Res., turkey oak sandhills, *S.B. Jones 15123* (USF). **SOUTH CAROLINA. Aiken Co.:** N of Graniteville, Interstate-20, embankment, road right-of-way, 8 Sep 2003, *J. Semple & B. Semple 11218* (WAT).

Solidago lepida DC. subsp. **fallax** (Fernald) Semple, stat. nov. BASIONYM: *Solidago lepida* DC. var. *fallax* Fernald, Rhodora 17:9–10. 1915. Fl. S. Brit. Columbia 301. 1915. *Solidago elongata* Nutt. var. *fallax* (Fernald) G.N. Jones, Univ. Wash. Publ. Biol. 5:242. 1936. *Solidago canadensis* L. var. *fallax* (Fernald) Beaudry, Naturaliste Canad. 95:37. 1968. TYPE: CANADA. NEWFLOUNDLAND: Harry's River, gravelly thicket, 18 Aug 1910, *Fernald & Wiegand 4108* (HOLOTYPE: GH!; ISOTYPE: NY photo!).

A discussion of all species in *Solidago* subsect. *Triplinervae* is in preparation to explain the taxonomic treatment of the subsection in Semple and Cook (submitted). In the treatment, *S. lepida* is the very sparsely to moderately glandular member of the subsection. Subspecies *lepida* is primarily a western taxon found from Alaska through the mountains to northern Californa and New Mexico and across northern Canada to Ontario and rarely to New Brunswick and the Gaspé, Québec. Subspecies *fallax* occurs in Newfoundland south to New Brunswick and rarely to northern Ontario. It has upper stems leaves with more numerous and larger serrations than occur on leaves of either var. *lepida* or var. *salebrosa* of subsp. *lepida*. Subspecies *fallax* is only very sparsely glandular with minute stipitate glands on the phyllary margins or tips.

Solidago lepida DC. var. **salebrosa** (Piper) J.C. Semple, comb. nov. BASIONYM: *Solidago serotina* Ait. var. *salebrosa* Piper in Piper & Beattie, Fl. Palouse Region, 185. 1901. *Solidago canadensis* L. var. *salebrosa* (Piper) M.E. Jones, Bull. Univ. Montana, Biol. ser. 15:49. 1910. *Solidago salebrosa* (Piper) Rydb., Fl. Rocky Mts. 870, 1067. 1917. *Solidago gigantea salebrosa* (Piper) Friesner, Butler Univ. Bot. Stud. 4:196. 1940. *Solidago gigantea* Ait. var. *salebrosa* (Piper) Friesner, Butler Univ. Bot. Stud. 5:113. 1941. *Solidago canadensis* L. ssp. *salebrosa* (Piper) Keck, Aliso, 4:104. 1958. TYPE: U.S.A. WASHINGTON: Pullman, Piper 1580 (HOLOTYPE: WS!; ISOTYPE: GH!)

Minute stipitate glands occurs on capitulescence structures (upper most stem leaves, bracts, peduncles and/or phyllaries) in *S. lepida* var. *salebrosa*, which differs from var. *lepida* in having arching, elongated lower branches in the capitulescence.

Solidago odora Aiton subsp. **chapmanii** (A. Gray) J.C. Semple, comb. nov. BASIONYM: *Solidago chapmanii* A. Gray, Proc. Amer. Acad. 16:80. 1880. *Solidago odora* Ait. var. *chapmanii* (A. Gray) Cronq., Brittonia 29:224. 1977. SYNTYPES: U.S.A. FLORIDA: "pine barrens, *Chapman s.n.* (GH!, NY photo!). Levy Co.: Nov 1877, *Dr. Gar-*

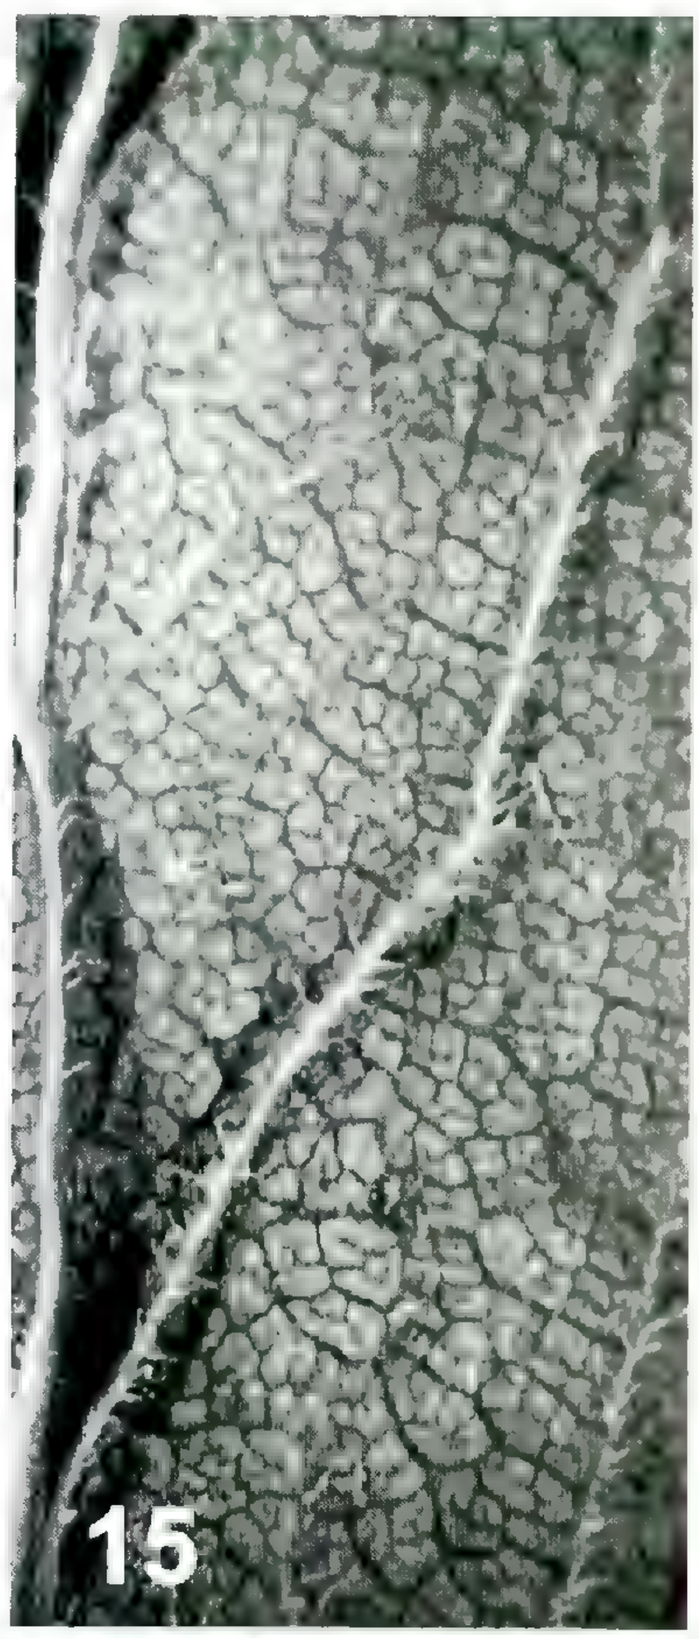
ber s.n. (GH!, LECTOTYPE, here designated; GH!, ISOLECTOTYPE, here designated). The Garber collections at GH are marked `n.sp. A. Gray'; the Chapman collection at GH is not. The Lectotype was selected because the label includes in Gray's hand "odorless form" and has heads in anthesis; its capitulescence has elongated lateral branches due to damage to the apex of the primary axis. The other Garber collection has two shoots, both with primarily fruiting heads.

Solidago patula Muhl. ex Willd. subsp. **strictula** (Torr. & A. Gray) J.C. Semple, stat. nov. BASIONYM: *Solidago patula* Muhl. var. *strictula* Torr. & A. Gray, Fl. N. Amer. 2:213. 1841. TYPE citation: "North Carolina! to Florida! and Louisiana!" SYNTYPES: U.S.A. LOUISIANA: *Drummond s.n.* (GH!, LECTOTYPE designated here because it is a more complete specimen; narrow-paniculate secund capitulescence and lower portion of stem with petiolate leaves, T. & G. FNA label annotated by Gray as "S. patula [beta] strictula"). *Hale s.n.* (GH!; narrow-paniculate capitulescence and portion of upper stem; on the same sheet with the Lectotype). Another collection by Drummond at GH has several labels: 1) "Jacksonville, Louisiana. T. Drummond. Hooker misit January 1835"; 2) "1870 Herb. From Herb J. Gay purchased by Dr. Hooker"; 3) "S. patula var. strictula" in Gray's hand on his SYN. FL. N. AMER. label; and 4) an annotation by Dr. G. Morton 1970 with the identification "*Solidago patula* Muhl." While this specimen was seen by Gray at some point, there is no indication it was seen before 1841 and, therefore, is rejected as a possible syntype.

Solidago puberula Nutt. subsp. **pulverulenta** (Nutt.) J.C. Semple, comb. et stat. nov. BASIONYM: *Solidago pulverulenta* Nutt., Gen. Pl. 161. 1818. non Bush (1918). *Solidago puberula* var. *pulverulenta* (Nutt.) Chapm., Fl. South. U.S. 210. 1860. TYPE: U.S.A. GEORGIA: s.d., *Nuttall s.n.* (HOLOTYPE: not seen; possible ISOTYPE: DH-122552!).

Solidago rugosa Mill. var. **cronquistiana** Semple, var. nov. (**Figs. 12–18**). TYPE: U.S.A. NORTH CAROLINA. Mitchell Co.: top of Roan Mt., 6250 ft. el., Forest Rd.-30 near parking lot, 15 Sep 1991, *Semple & Suripto 9666* (HOLOTYPE: WAT; ISOTYPES to be distributed: MO, NCU, NY).

Solidagini rugosi var. *asperi* accedens sed capitulescentia ramis brevibus foliis subtentibus nunc vix longioribus nunc brevioribus et caulibus sparsim hispidis differt.



Solidago rugosa var. *cronquistiana* possesses a mixture of traits that are seen in both var. *aspera* and var. *rugosa* (the *villosa* morph). The leaves are usually strongly rugose like those of var. *aspera*, but not as densely hairy. The branches of the elongated capitulescence are usually short and more like those seen in morphs of var. *rugosa* traditionally assigned to the var. *villosa*, but lacking the dense pubescence of the latter. The lowest capitulescence branches of very robust plants can be elongated and repeat the pattern of the upper portion of the capitulescence (e.g. *Semple & Suripto 9829*); a similar phenomenon is seen in the virgate capitulescences of robust plants of other species of goldenrods such as *S. hispida* and *S. bicolor*. Based on field observations and knowledge of type material in *S. rugosa*, my first impression of the type collection made in 1991 was that it did not fit well into any previously described race of the *S. rugosa* complex. Additional collections were made in the Appalachian Mts. of North Carolina and extreme northern Georgia. The taxon likely also occurs at higher

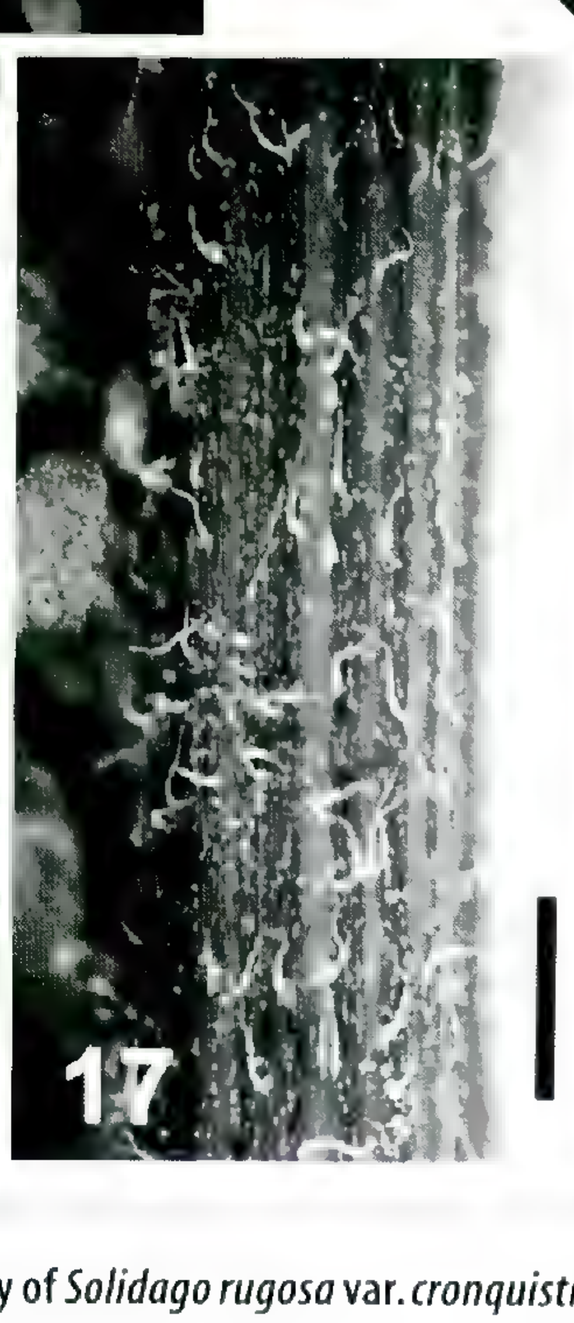


FIG. 12. Holotype of *Solidago rugosa* var. *cronquistiana, Semple & Suripto 9666* (WAT).

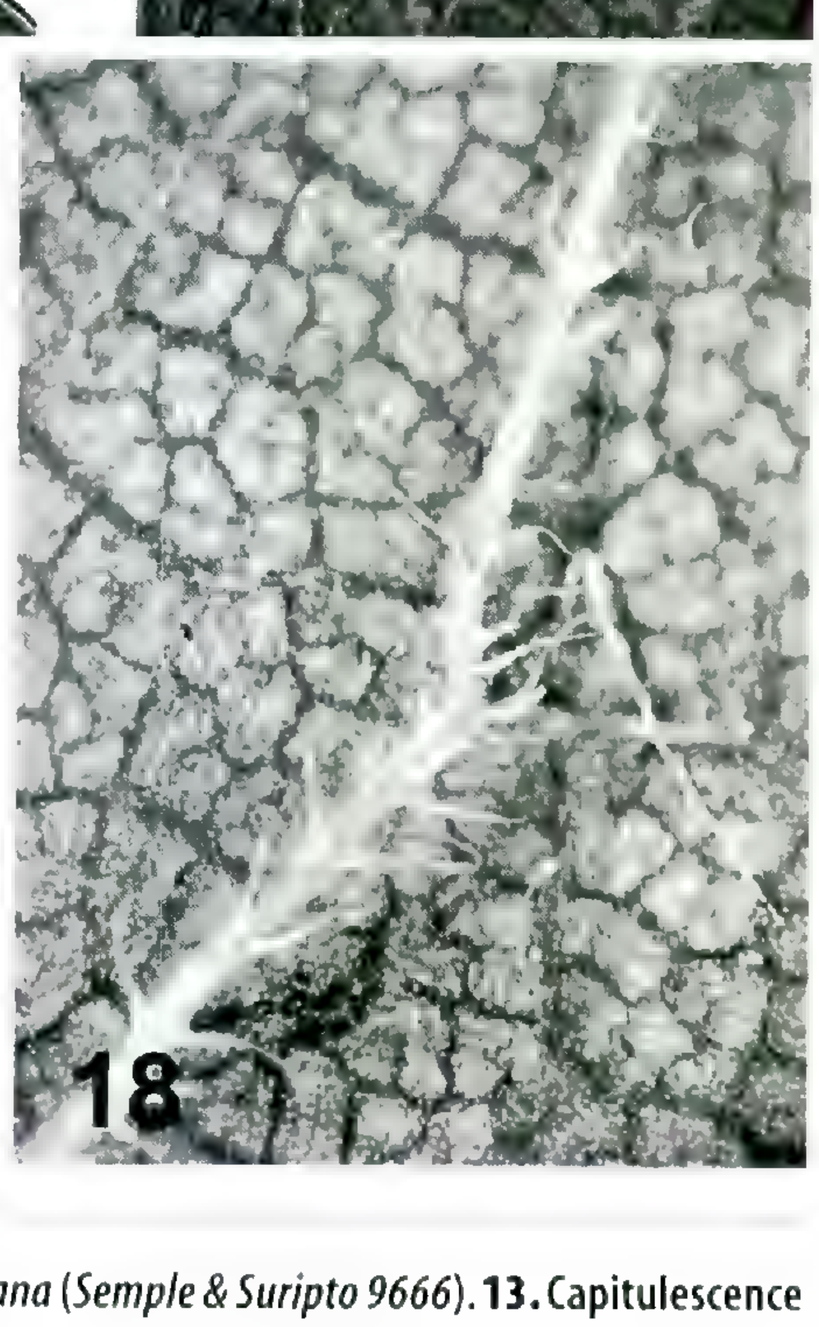

FIGS. 13–18. Details of the morphology of *Solidago rugosa* var. *cronquistiana* (*Semple & Suripto 9666*). **13.** Capitulescence of wild plant with wasp visitor. **14.** Mid stem leaf, abaxial surface. **15.** Detail of abaxial surface of upper mid stem leaf. **16.** Upper mid stem. **17.** Stem just below capitulescence. **18.** Enlarged area of lateral vein shown in 15. Scale bars in 16–17 equal 1 mm.

elevations in adjacent eastern Tennessee and western Virginia. All chromosome determinations made for the new variety were tetraploid. Overall, var. *cronquistiana* appears closer to var. *aspera* than to var. *rugosa* and is thus assigned to subsp. *aspera*.

The new variety is named in honor of the late Dr. Arthur Cronquist, whose work on composites is well known and whose occasional phone calls (usually at night or on weekends) on matters Astereae were both enlightening and entertaining.

Additional collections of var. *cronquistiana*: **GEORGIA. Rabun Co.:** GA-15 2 km N of Tallulah Falls, 21 Sep 1991, *Semple & Suripto 9828* (WAT). **NORTH CAROLINA. ABSTRACT

The pappus in the goldenrod genus *Solidago* (Asteraceae: Astereae) was examined in 75 species and compared with variation in 14 species of 12 related genera in subtribe Solidagininae in the narrow sense following Nesom (2000) and three species of asters of two genera basal to the North American Clade of the tribe. *Solidago* has been described as having a simple pappus consisting of one whorl of barbellate bristles with the exception of a few species in several sections, sometimes treated as distinct genera. Species of *Solidago* sect. *Corymbosae* (*Oligoneuron*) have long been recognized as having a biseriate pappus with clavate bristles similar to that of other genera of the subtribe. However, nearly all species of *Solidago* displayed some evidence indicating the pappus bristles occur in two more or less heteromorphic whorls of bristles, here designated as the primary outer whorl and the primary inner whorl. A few species also occasionally had a third, much shorter secondary outer whorl of a few bristles. In the most heteromorphic species, the primary outer whorl of bristles was slightly shorter and had tips that gradually tapered. The primary inner whorl of slightly longer bristles had distinctly clavate tips up to several times as broad as the bristle below the tip. As well, the bases of the primary outer whorl were clearly external to those of the primary inner clavate whorl in some species. In contrast, most species in several subsections of the genus exhibited little evidence of a biseriate pappus or clavate bristle tips. The pappus of each species was scored on several traits: 1) non-clavate to distinctly clavate bristle tips, 2) evidence of alternating non-clavate and clavate bristles or shorter and longer bristles, and 3) evidence of overlapping primary outer and inner whorls of bristles. One species of *Solidago* had an atypically short pappus; the bristles of *S. sphacelata* were less than half the length of the cypsela body. The biseriate pappus of *Brintonia discoidea* was usually tinted with anthocyanotic pigments unlike any species of *Solidago*; the species has been included in *Solidago* by some authors.

RESUMEN

Se examinó el vilano en 75 especies del género *Solidago* (Asteraceae: Astereae) y se comparó con la variación en 14 especies de 12 géneros relacionados de la subtribu Solidagininae en sentido restringido según Nesom (2000) y tres especies de asteráceas de dos géneros basales al clado Norte Americano de la tribu. *Solidago* se ha descrito como poseedor de un vilano simple que consiste en un verticilo de sedas barbeladas, con la excepción de unas pocas especies en varias secciones, a veces tratadas como géneros diferentes. Las especies de *Solidago* sect. *Corymbosae* (*Oligoneuron*) han sido reconocidas por presentar un vilano biseriado con sedas clavadas similares a las de otros géneros de la subtribu. Sin embargo, casi todas las especies de *Solidago* muestran algunas pruebas que indican que las sedas del vilano se sitúan en dos verticilos más o menos heteromórficos, que aquí se nombran como verticilo primario externo y verticilo primario interno. Unas pocas especies también tienen ocasionalmente un tercer verticilo, el verticilo secundario externo, mucho más corto y de unas pocas sedas. En la

[1]Author of correspondence.

especie más heteromórfica, el verticilo primario externo de sedas era ligeramente más corto y tenía extremos gradualmente afilados. El verticilo primario interno, de sedas ligeramente más largas, tiene extremos claramente clavados de hasta varias veces más anchos que la propia seda debajo del extremo. Así mismo, las bases del verticilo primario externo eran claramente externas a las del verticilo primario interno clavado en algunas especies. Por contra, la mayoría de las especies de varias subsecciones del género mostraban pocas pruebas de un vilano biseriado o de extremos de las sedas clavados. El vilano de las distintas especies fue escrutado en varios aspectos: 1) extremos de las sedas de no-clavadas a distintamente clavadas, 2) evidencia de alternancia de sedas no-clavadas y clavadas o sedas más cortas y más largas, y 3) evidencia de solapamiento de los verticilos de sedas primario externo e interno. Una especie de *Solidago* tenía un vilano atípicamente corto; las sedas de *S. sphacelata* eran menos de la mitad de la longitud del cuerpo de la cipsela. El vilano biseriado de de *Brintonia discoidea* estaba normalmente teñido con pigmentos antociánicos, cosa que no ocurre en las especies de *Solidago*; la especie ha sido incluida en *Solidago* por algunos autores.

INTRODUCTION

Previously the genus *Solidago* L. was considered different from closely related genera in regards to its pappus characteristics. While related taxa such as *Sericocarpus* Nees, *Tonestus* A. Nels., *Petradoria* E.L. Greene, *Chrysothamnus* Nutt. and *Ericameria* Nutt. were considered to have a pappus in 2–3 series (1–2 for *Tonestus*), the genus *Solidago* was stated to have a pappus in a single series (e.g., Semple et al. 1999; Nesom 2000). It has also been described as simple (Fernald 1950; Correll et al. 1970). Some treatments do not mention anything about the seriate nature of the pappus in the genus description (Radford et al. 1968; Cronquist, 1980; Gleason and Cronquist 1991), although variations are indicated in species descriptions. Some treatments state that the pappus of *Solidago* exhibits some variation. Gleason and Cronquist (1991) recorded the pappus as being "of numerous equal or sometimes unequal capillary bristles" for species from the northeast U.S.A. and adjacent Canada, while Cronquist (1994) noted the pappus as being "equal or sometimes somewhat unequal" in Great Basin species. Some of the differences in description are due to differences in which taxa were included in the genus *Solidago*, particularly the generally recognized clavate tipped members of *Solidago* sect. *Corymbosae* Torrey & A. Gray. For example, Cronquist (1980) included these flat-topped goldenrods, but excluded *Brintonia discoidea* (Elliott) E.L. Greene, the Mock Goldenrod. In contrast, Nesom (2000) excluded the former species placing them in the genus *Oligoneuron* Small, but included *Brintonia discoidea* as *S. discoidea* (Elliott) Torrey & A. Gray. Nesom (1991) discussed morphological reasons for treating *B. discoidea* within *Solidago*. Semple (submittted) treated *Brintonia* as a separate genus based on morphology (phyllary traits, disc corolla traits, pappus traits), field observations and DNA studies (Beck and colleagues, pers. comm.). *Solidago sphacelata* Raf. has been treated as *Brachychaeta sphacelata* (Raf.) Britt. due to its distinctive short pappus, but the general consensus recently is to retain it within *Solidago* (Cronquist 1980; Nesom 1991, 1993; Semple and Cook, submitted). Other authors in the past have included *Euthamia* (Nutt.) Nutt.,

Oreochrysum Rydberg, or *Petradoria* in *Solidago*, there by increasing the range of variation in pappus traits within the latter genus (e.g., Fernald 1950; Kearney & Peebles 1951; Harrington 1964; Semple et al. 1999).

The details of pappus bristle shape have generally been overlooked and descriptions have included various terms. Most have described the pappus of *Solidago* as "capillary" or "hair-like" (Fernald 1950; Radford et al. 1968; Correll & Johnston 1970; Cronquist 1980, 1994; Gleason & Cronquist 1991). Some treatments mention the pappus of *Solidago* as being "barbellate" or "clavate" in some species (Cronquist 1980, *S. ptarmicoides* (Torrey & A. Gray) Boivin; Semple et al. 1999, *S. houghtonii* Torrey & A. Gray, *S. ptarmicoides* (as *S. asteroides* Semple), *S. sempervirens* L.). Pappus bristles of *Solidago* and closely genera have been described as being "barbellate" (Nesom 2000). Nesom (1993) in his overview of *Solidago* and *Oligoneuron* used pappus bristle apex features as taxonomic characters: "strongly clavate," "attenuate," and "slightly but distinctly dilated toward the apex." He listed these in descriptions of sections and subsections, and noted the character state of pappus bristles for some species in particular.

The occurrence of a biseriate to multiseriate pappus has long been reported in other genera in the Tribe Astereae in both the North American Clade, which includes *Solidago* (see Semple et al. 2002), and the Basal Grade of South American and Old World Genera. The more basal genera in the North American Clade are biseriate or triseriate with bristles of equal or different lengths. These include most of the genera included traditionally in the Old World genus *Aster* L.: *Doellingeria* Nees, *Eucephalus* Nutt., *Ionactis* E.L. Greene, *Oclemena* E.L. Greene, *Sericocarpus*. Most species in subtribe Chrysopsidinae Nesom are biseriate, having a short outer whorl and a much longer inner whorl. In contrast, the pappus of some genera is typically uniseriate, e.g. *Symphyotrichum* Nees. In some cases the usual barbellate bristles are absent or very reduced, e.g. ray floret cypselae of *Heterotheca* sect. *Heterotheca*, *Aphanostephus* DC. The number of bristles varies greatly between species within and between genera as well. Thus, within the North American Clade of genera of Astereae there exists a range in the number of whorls, their relative lengths and their shapes (see Nesom 2000 for general descriptions of genera). No detailed systematic examination of the pappus of most or all species of *Solidago* has been reported. Our study was undertaken to fill in this gap in knowledge.

MATERIALS AND METHODS

A preliminary survey was undertaken to examine under the dissecting microscope the pappus bristles of one or two specimens of representative species of the sections and subsections of *Solidago*. Subsequently, a more rigorous survey was conducted involving 75 species of *Solidago* and 17 species of 14 other genera listed in Table 1. Two methods of observation were employed, and a system of ranking the degree of the clavateness of bristle tips was developed. Most ob-

Some Other Genera of the Solidagininae sensu Nesom (2000)				
Brintonia discoidea[2]	3	Yes	Yes (slight)	bristles tinted with anthocyanins; biseriate pappus
Chrysoma pauciflosculosa	2	Yes	Yes	strong overlapping; secondary outer whorl of much shorter tapering bristles; primary outer whorl slightly shorter bristles tapering to weakly clavate; primary inner whorl of longer somewhat clavate bristles

Taxon	Clavate[1]	Alternating	Overlapping	Comments
Chrysothamnus viscidiflorus	1	Yes	Yes	obvious biseriate pappus
Ericameria laricifolia	3	Yes	Yes	obvious biseriate pappus
Ericameria discoideum	1	Yes	Yes	biseriate pappus
Euthamia graminifolia	0	Yes	No	variation in bristle length obscures weak pattern of short-long alternation of bristles
Gundlachia corymbosa	0–2	Yes	No	weakly biseriate with the two whorls alternating; primary outer slightly shorter, tapering; primary inner longer, weakly clavate
Gutierrezia sarothrae	0	No	No	crown of irregular some-what erose scales of varying lengths and widths
Hesperadoria scopulorum	1	Yes	Yes	multiiseriate pappus; primary whorls of many Longer bristles, one shorter outer secondary whorl of fewer bristles
Oreochrysum parryi	1	Yes	Yes (slight)	
Petradoria pumila	1	Yes	Yes	obvious biseriate pappus
Sericocarpus				
S. linifolia	4	Yes	Yes	obvious biseriate pappus; outer whorl slightly shorter than inner
S. oregonensis	4	Yes	No	possible slight overlapping at base of whorls
Tonestus pygmaeus	4	Yes	Yes	
Genera Basal to the North American Clade				
Doellingeria umbellata	3	Yes	Yes	triseriate; short outer third whorl
Eucephalus				
E. breweri	2	Yes	Yes	triseriate pappus
E. elegans	4	Yes	Yes	biseriate, possible weakly triseriate

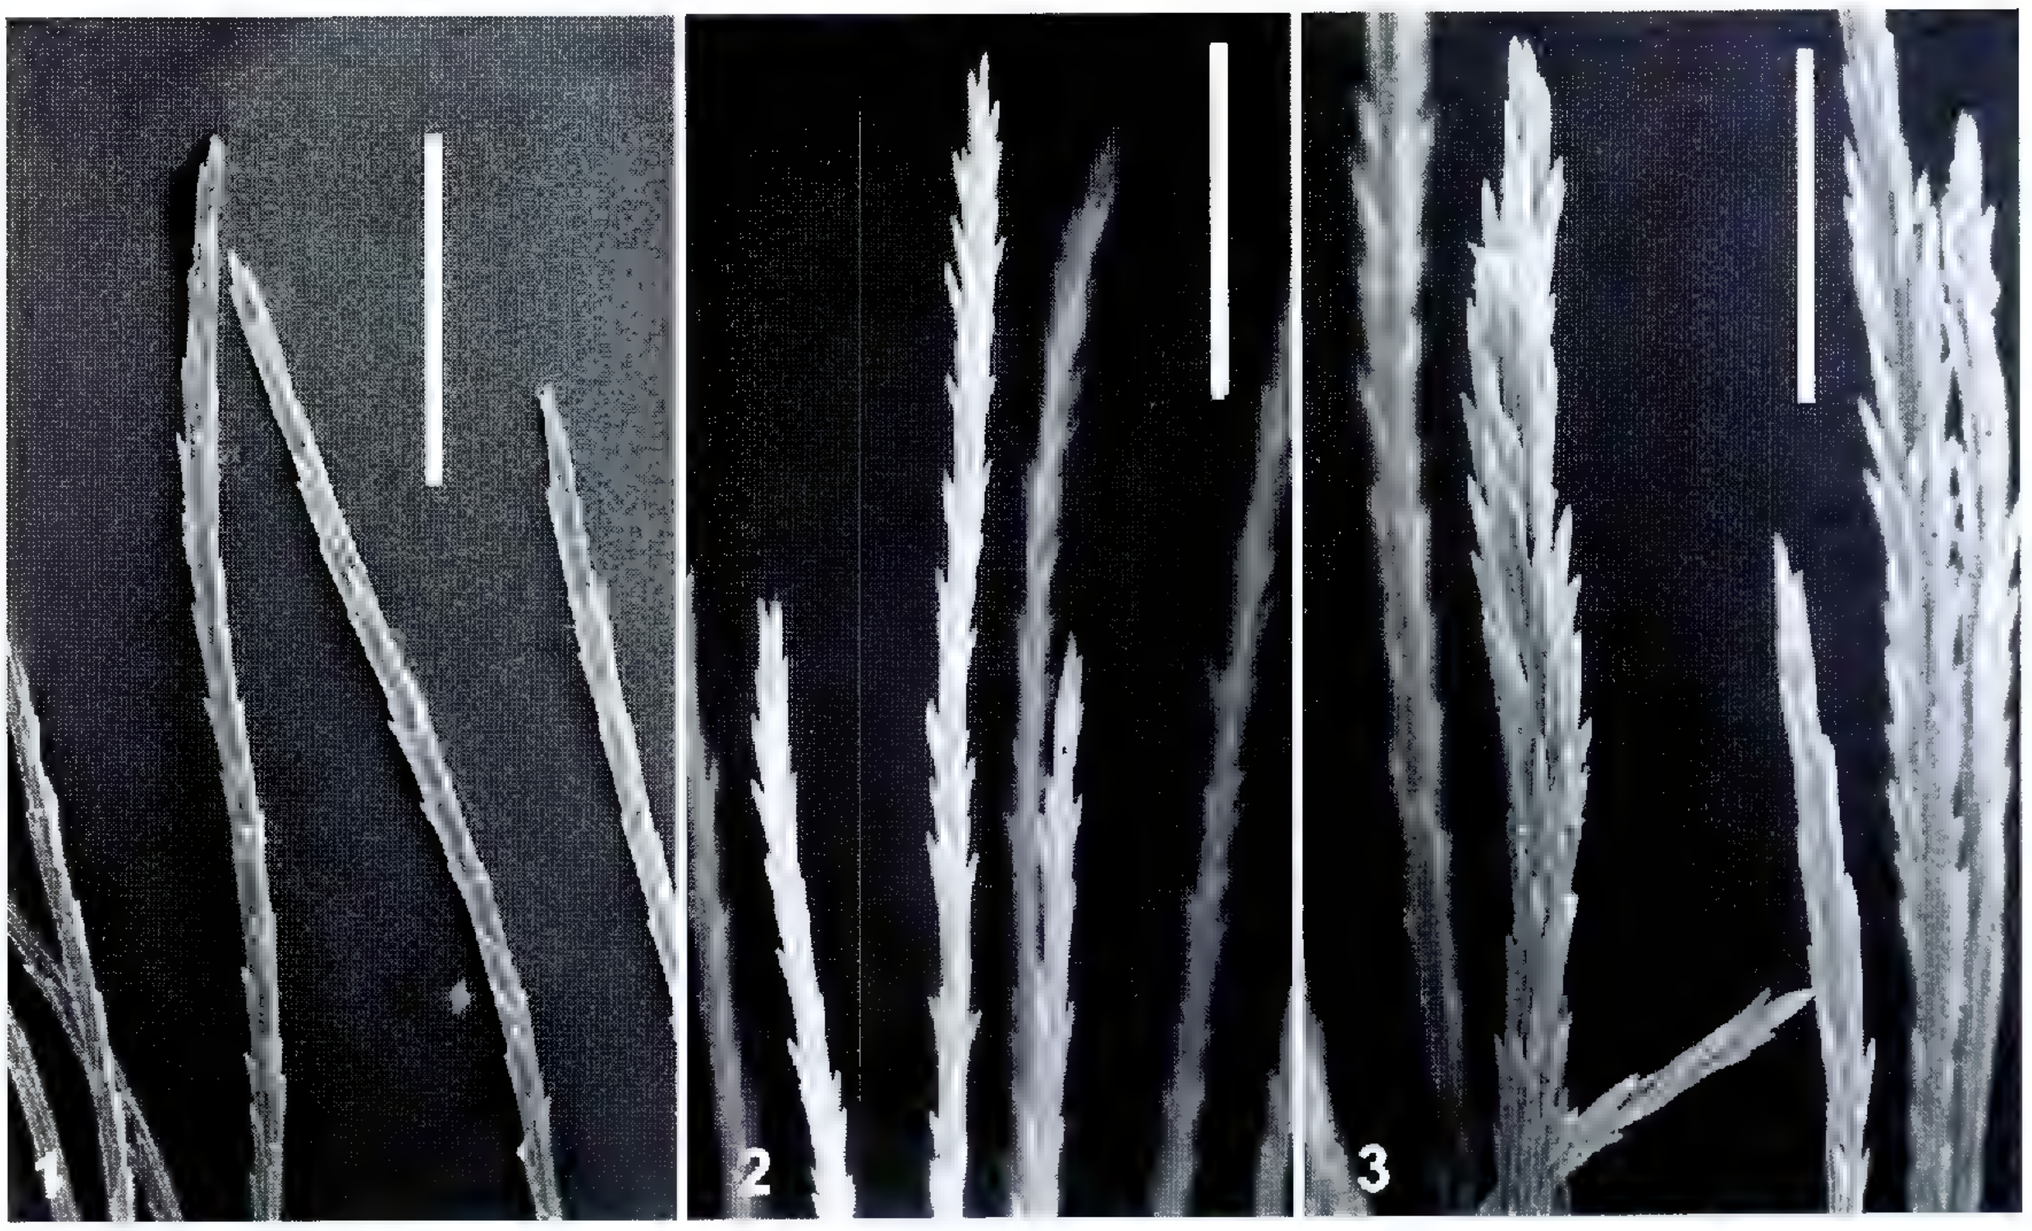
[1] arbitrary ranking of 0 (not clavate) to 4 (strongly clavate)

[2] treated as *Solidago discoidea* by Nesom (1993)

servations were made using a dissecting scope or a compound light microscope. Some observations were made using dried and gold coated specimens on a Hitachi S-570 Scanning Electron Microscope (SEM). At least five different fruits from each species were observed under the dissecting microscope at a maximum of 70×; most observations were made at 30×. In some cases multiple dozens of specimens of a species were examined. For the most part, observations were made on specimens in the WAT Herbarium, but additional material on loan from BRIT, F, GH, JEPS, NY, TEX and UC (Holmgren et al. 1990) was also examined.

Observations on the compound microscope were made from slides prepared as follows. For each species, two ray floret and two disc floret cypselae with corollas were mounted in DepeX mounting medium under a cover slip. Observations at 100× on the compound microscope were made similarly to the observations under the dissecting scope at 30×–70×. Observations made on the two kinds of scopes were compared and any discrepancies were resolved by re-examining specimens.

Each taxon was scored in the following manner:



1. Cypselae were assigned a number from 0–4 depending on the thickness of the tip of the bristle in relation to the thickness along the length: 0 = no observable increase in thickness and the bristles tapered to a point (Fig. 1); 1 = a very slight increase in thickness near the tip, or the bristles not tapering gradually; 2 = a slight to moderate increase in thickness near the tip (Fig. 2); 3 = a strong and obvious presence of clavate tips; and 4 = very noticeable increase in thickness, very obvious clavate nature of the bristles (Fig. 3). A set of reference light-microscopy photomicrographs were used to maintain consistency in assigning values.

2. Cypselae were scored as showing no evidence of alternation of primary inner and outer whorls of bristles or as showing evidence of alternating with the notes on the nature of the alternation (No or Yes in Table 1, respectively).

3. Cypselae were scored for evidence of overlapping at the bases of the outer and inner whorls of bristles. The taxa examined were graded in three categories regarding the overlapping of the bristles at the base: Yes = complete overlap of bristles; Yes (slight) = slightly overlapping with outer whorl bristles consistently appearing external to inner whorl bristles; and Yes (random) = overlapping of some outer bristles external to inner bristles but not consistently so for the two whorls.

4. Notes were made when a secondary outer whorl (a third whorl) of very short barbellate bristles was observed. Such bristles were not easily observed and occurred in low numbers, thus the presence or absence of such bristles was not tabulated.

Digital photomicrographs were taken using a Nikon CoolPix 990 camera manually held against the ocular lens of either the dissecting or compound

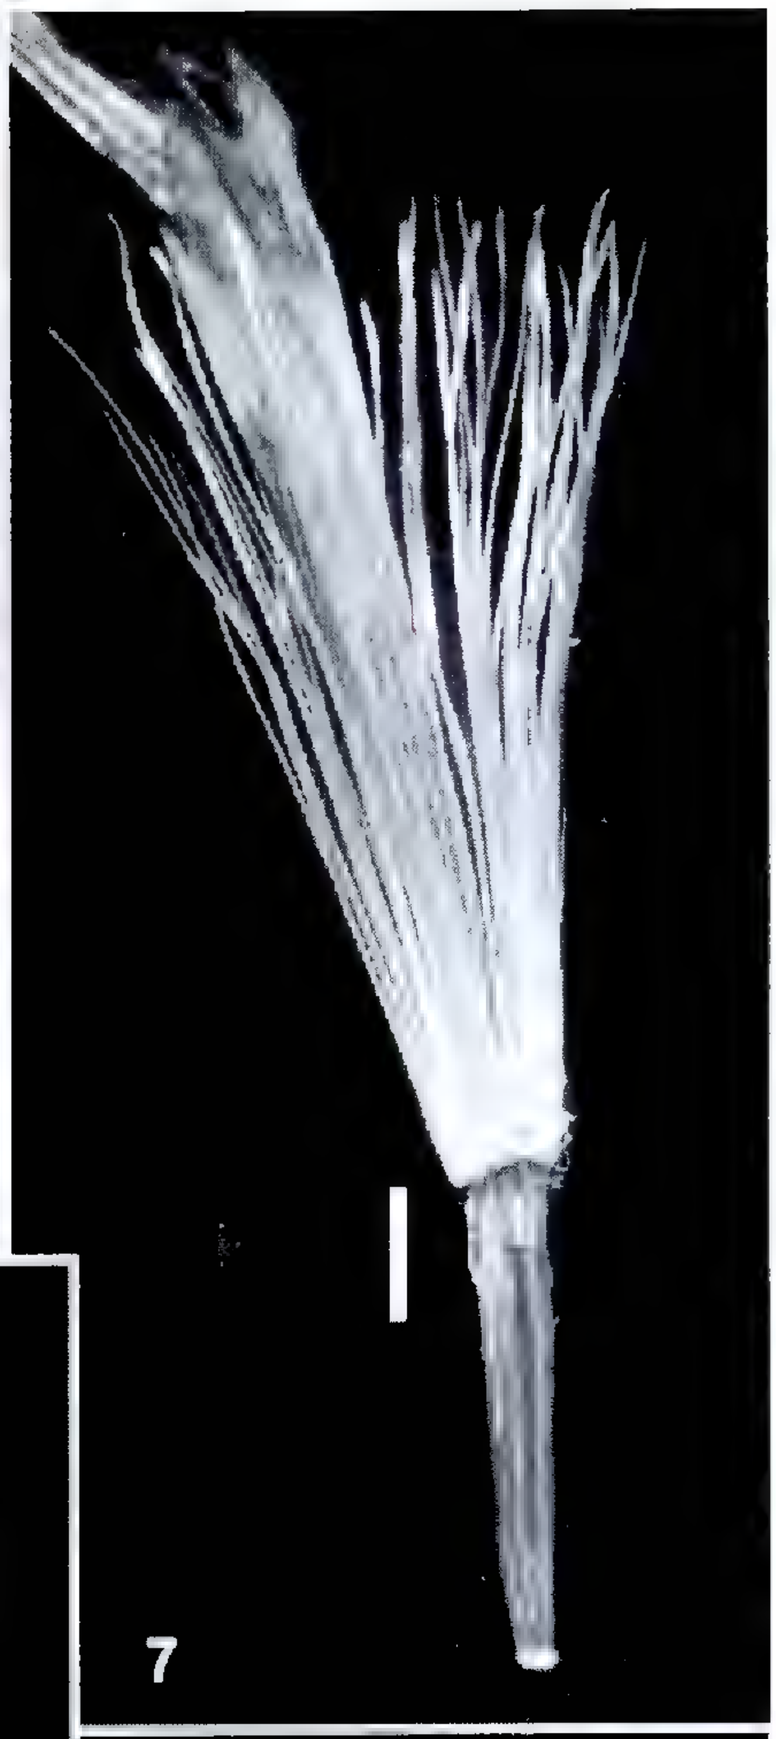
microscope. Pictures were taken of specimens under the compound light microscope with either below stage or above stage lighting. SEM photomicrographs were made using Ilform Pan F film commercially developed and subsequently digitized by scanning the negatives. Final digital illustrations were made using CorelDraw 10® from digital images edited with Corel PhotoPaint10® (Corel Corp.).

RESULTS AND DISCUSSION

The lack of a standard set of terms for pappus bristle whorls in *Solidago* and other genera lead to some confusion in discussing the results between the authors and for the reviewer. The following labels are presented as potential future "standard" terms for discussing pappus whorls in the Astereae. Because a biseriate pappus is found in many genera of the tribe, we recommend that these two whorls of bristles be referred to as the "primary outer whorl" and the "primary inner whorl." The primary inner whorl often is longer and has slightly to strongly clavate bristle tips. The third, often much shorter, outer whorl present in some genera can be referred to as the "secondary outer whorl." These labels for bristle whorls are used consistently throughout this paper. The term "secondary" with appropriate modifiers can be applied to any additions whorls, e.g. a secondary innermost whorl of non-clavate long bristles.

The pappus of the genus *Solidago* is usually biseriate, although obscurely so in some species. In most species the pappus exhibited either alternation of

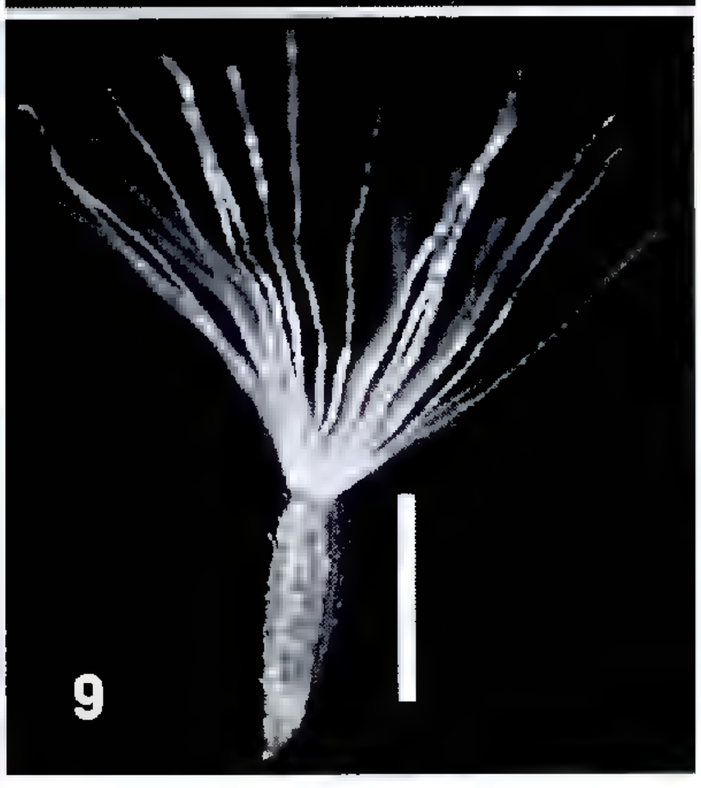
shorter and longer bristles, alternation of clavate and non-clavate bristles, or some degree of basal overlapping of outer and inner bristles of the primary inner and outer whorls. Table 1 lists observations on the degree of clavateness of bristle tips, presence or absence of evidence of alternation of whorls of bristles, degree of basal overlapping of outer and inner long whorls, and specific observations on 75 species of *Solidago* and 17 species of 14 related genera. Species of *Solidago* are grouped within Table 1 by section, subsection and series following the treatment of the genus by Semple (Semple et al. 1999; Semple 2003; Semple, submitted; Cook and Semple, submitted, treatment of *Solidago* for Flora North America). There is a large range in size of the cypselae bodies and length of the pappus bristles among species of *Solidago* (Figs. 4–9). Bristles can be much shorter than to four times longer than the fruit body, and bristle length ranged from 0.25–7.5 mm. Cypsela bodies varied from 0.5–5 mm in length and from glabrous to densely short strigose. The number of bristles per cypsela ranged from about 25 (Fig. 9 , *S. canadensis*) to more than 40 (Fig. 6, *S. auriculata*). On average, pappus bristles were slightly shorter than the disc corollas (averaging about 9/10 as long comparing the mature pappus to the disc corolla length at anthesis based on data in Semple and Cook, submitted).

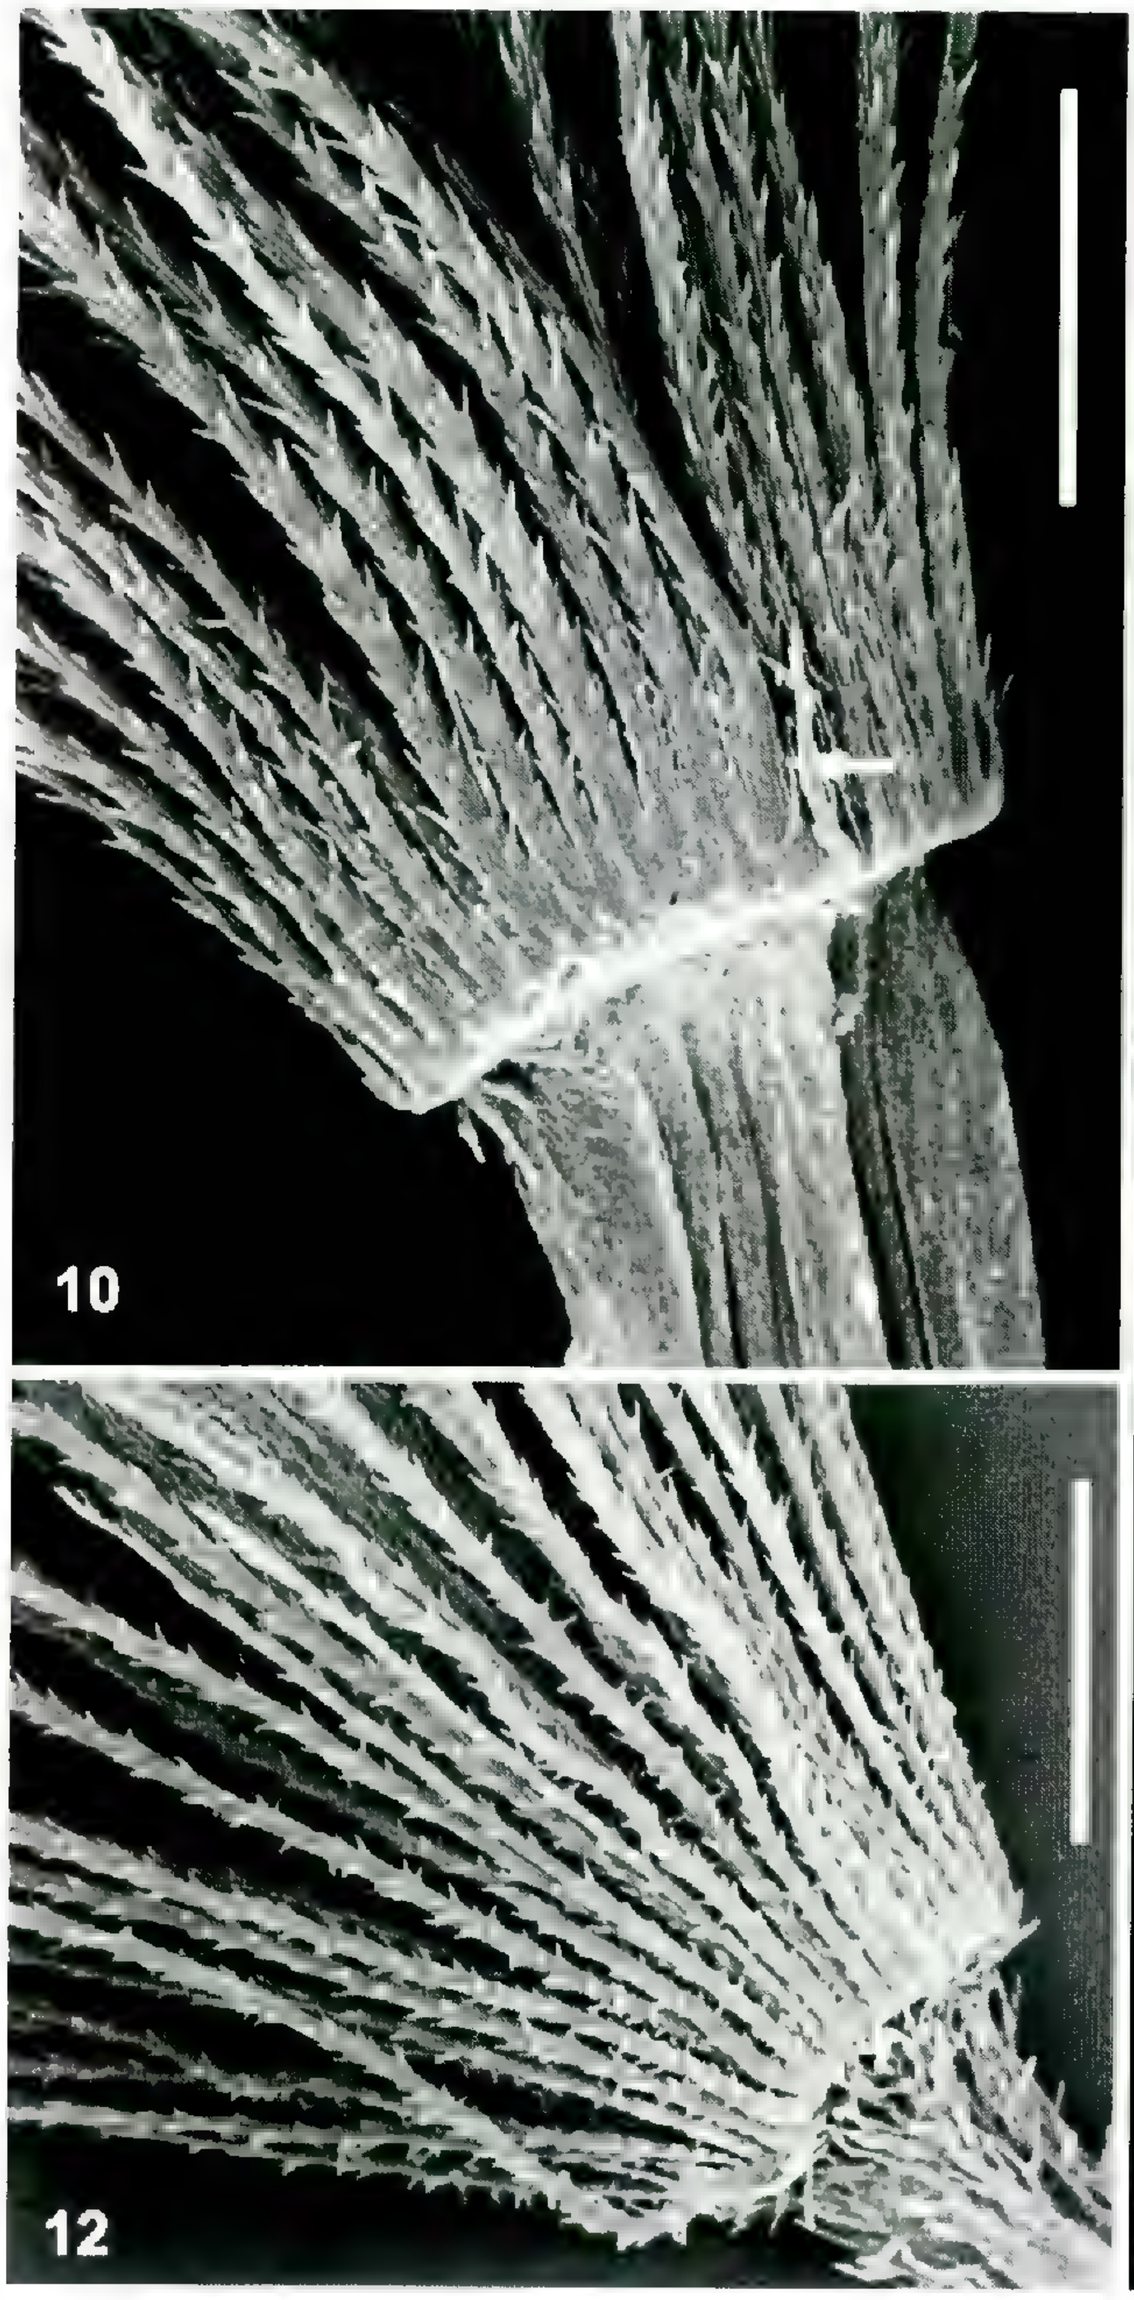


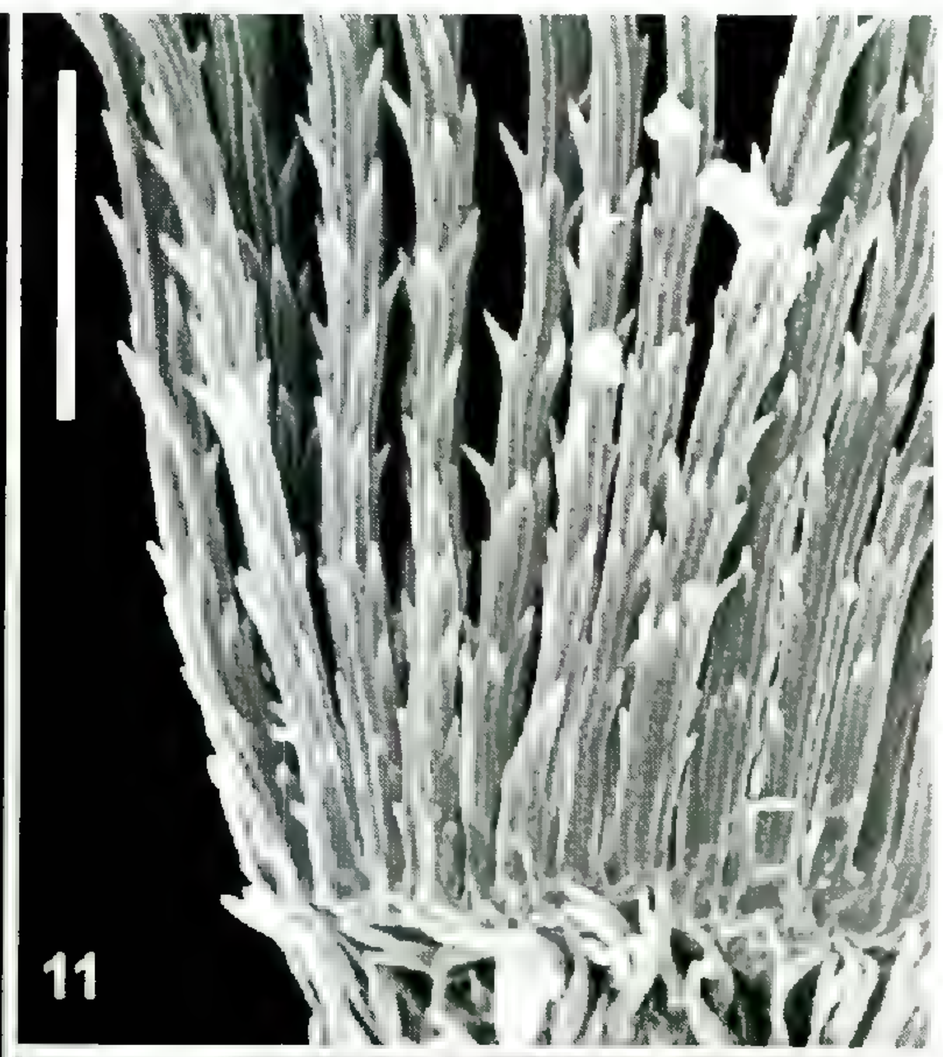
Some of the pappus bristles in the majority of species of *Solidago* were observed to be more or less clavate, and these were the primary inner whorl bristles in taxa where position of the whorls could be determined. About 25% of the species examined had, relative to other species, broad clavate bristle tips on the primary inner whorl of bristles, e.g., *S. auriculata* (Fig. 6), *S. erecta* and *S. arguta*. Almost all species exhibited some indication of alternating clavate bristles and non-clavate bristles (Fig. 6), and some exhibited alternating between short bristles and long bristles, e.g. *S. ulmifolia*, (Fig. 13). Alternation of short and long bristles indicated a biseriate pappus even if little difference was observed in tip traits of the two whorls. Variation in the pappus of each species was observed but was of limited range; that is, bristles of a whorl could vary from scores of 0–2 or 3–4 for degree of clavateness, but not to the degree that some fruits had only non-clavate bristles while others of the same species had only strongly clavate bristles.

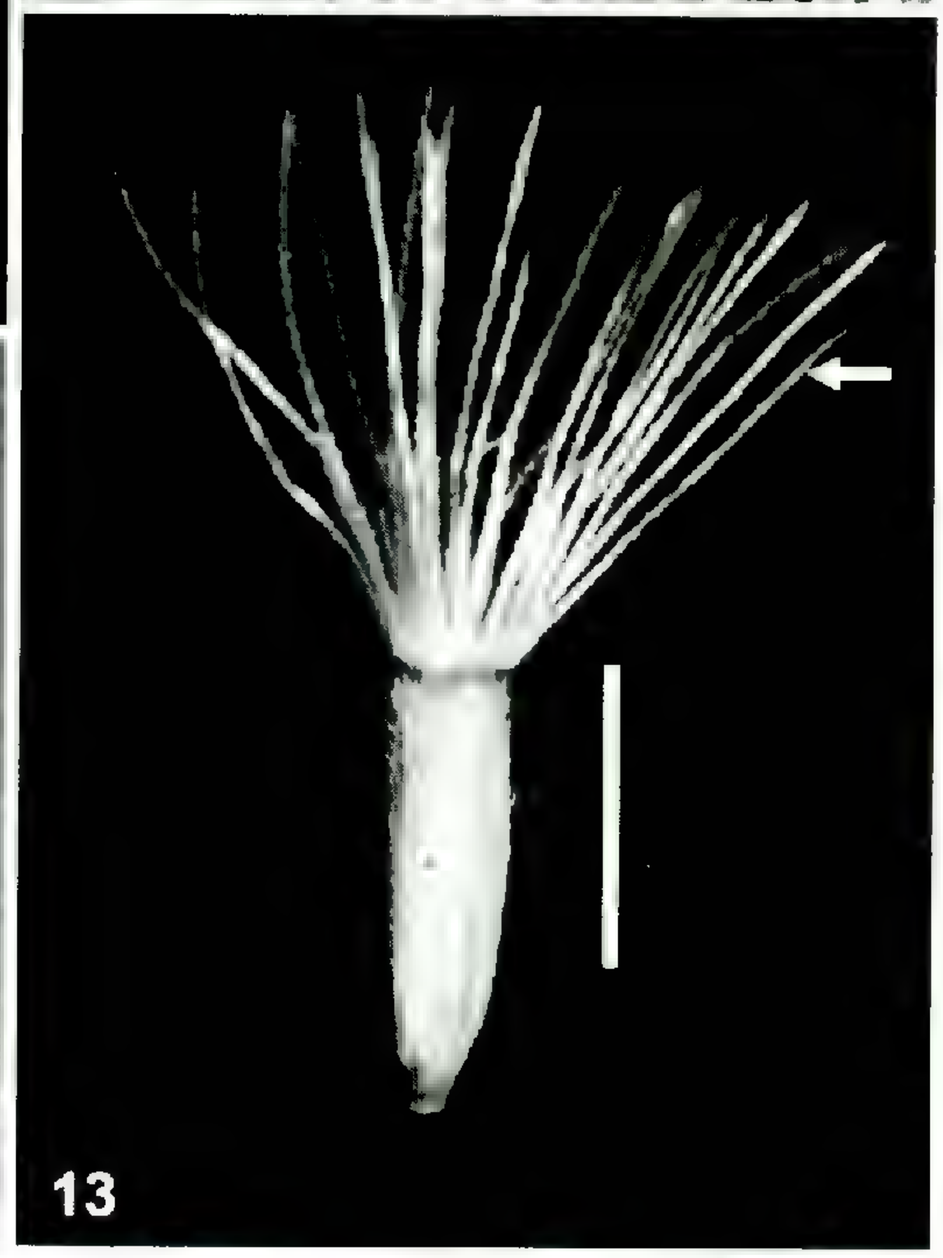
Some species had very clear overlapping of the bases of the primary whorls of bristles, e.g. *S. rigida* (Fig. 10) and *S. odora* (Fig. 12), while others (e.g., *S. bicolor* and *S. ulmifolia*) clearly had overlapping of some bases of the pappus bristles while other bristles on the same fruit did not appear to be overlapping. Many other species exhibited only slight overlapping of the bristle bases (e.g., *S. glomerata* and *S. multiradiata*) or random overlapping of some bristle bases but not in a clear primary inner whorl and primary outer whorl pattern. (e.g., *S. leavenworthii* and *S. simplex*). Some species appeared to have no overlapping bases, e.g. *S. altissima* (Fig. 11).

Some species of *Solidago* had a third, much reduced, secondary outer whorl









FIGS. 4–9. Length and number variation pappus bristles in *Solidago*; white scale bar = 1 mm. **4–5.** *Solidago sphacelata*, immature and mature cysellae, respectively. **6.** *Solidago auriculata*, maturing cypsela with disc corolla attached, scale bar = 1 mm. **7–8.** *Solidago macrophylla*, immature and mature cypselae, respectively. **9.** *Solidago canadensis*, mature cypsela.

of a few short barbellate bristles: e.g., *S. erecta* and *S. kralii*, *S. rigida* (Fig. 10) and *S. sempervirens*. This condition was difficult to observe and required searching at 70–100×. As noted in the Materials and Methods, detection of the presence of a third whorl was difficult because the few small bristles making up

FIGS. 10–13. Variation in pappus bristle whorls in *Solidago* (scanning electron micrographs). **10.** Biseriate-triseriate pappus, *S. rigida*, scale bar = 0.43 mm; arrow indicates short outer pappus bristle. **11.** Uniseriate pappus, *S. altissima*, scale bar = 100 :m. **12.** Biseriate pappus with clearly overlapping inner and outer whorls of bristles, *S. odora*, scale bar = 0.43 mm. **13.** Biseriate pappus with shorter outer whorl (arrow) and longer inner whorl of bristles, *S. ulmifolia*, scale bar = 1 mm.

the whorl could easily be missed. Thus, other species of *Solidago* than those noted in Table 1 may also occasionally produce a secondary outer whorl. Within the North American Clade of the Astereae a short outer whorl of bristles is known in other species, but it is not always clear whether the short bristles are the primary or the secondary outer whorl, e.g., all species of *Doellingeria*, some species of *Eucephalus*, almost all species of *Erigeron*, most species of the goldenaster subtribe Chrysopsidinae (Semple 1996; Nesom 2000; Semple et al.

2002). In *Doellingeria*, the short outer bristles clearly make up the secondary outer whorl. In other genera, the outer short bristles may be the secondary outer whorl or the primary outer whorl. Additional research is needed on these genera.

Within each section and subsection variation was seen in each of the features examined, but patterns were still present. The strongest evidence for a biseriate nature of the pappus of *Solidago* was observed in members of *S.* sect. *Corymbosae* and in *S.* subsect. *Albigulae*. Members of subsect. *Junceae*, subsect. *Maritimae*, subsect. *Venosae*, subsect. *Triplinervae* nearly always were observed to have non-clavate to weakly clavate bristle tips. In three species in the latter subsection, no evidence of a biseriate pappus was detected: *S. altissima*, *S. canadensis*, and *S. gigantea*. These species had no observable alternation, no clavate qualities to the bristles and no overlapping at the bases.

SYSTEMATICS IMPLICATIONS

The determination that *Solidago* species generally have a biseriate pappus with a primary inner whorl of clavate bristles means the genus is not aberrant within the Solidagininae sensu Nesom (2000). Of the taxa examined, the most distinct pappus was that of *Gutierrezia sarothrae* which had erose scales rather than barbellate and sometimes clavate bristles. The results mean that pappus traits are not useful in separating *Oligoneuron* (= *S.* sect. *Corymbosae* here) from *Solidago*. If authors wish to do so, then the argument will need to rely on other differences. Within the genus *Solidago*, there is sufficient variation in pappus traits among members of subsections and series that pappus traits can not be used as diagnostic features of any infrageneric group with one exception. The very short pappus of *S. sphacelata* is unique and is diagnostic for ser. *Brachychaeta*, if the series is treated as monotypic, as done here. Nesom (1993) defined the series by its cordate to truncate basal leaves with winged petioles, strongly reduced cauline leaves, 0–3 ray florets, and markedly short pappus bristles; he included *S. sphacelata*, *S. auriculata* and *S. brachyphylla*. The bristles of the latter two species are about 2/3 the length of the corollas, while those of *S. sphacelata* are about 1/4 to 1/5 the length of the corollas.

The most obvious conclusion to be drawn is that older descriptions of pappus traits of members of the Astereae may not be accurate or sufficiently detailed. Future descriptions should be based on very careful observations at high dissecting scope magnifications or lower powered compound microscope magnifications. Use of the labels "primary inner and outer whorls" and "secondary whorl(s)" should facilitate and standardize additional research on pappus whorl variation in the Astereae.

ACKNOWLEDGMENTS

This research was supported by a Natural Sciences and Engineering Council of Canada Discovery Grant to JCS and a University of Waterloo Undergraduate

Research Internship to JLAH. The technical assistance of Dale Weber on the scanning electron microscope is gratefully acknowledged. Guy Nesom is thanked for his useful review comments.

ABSTRACT

A new subspecies of *Polygonum sawatchense* Small is described and illustrated for the forthcoming treatments of the genus *Polygonum* (Polygonaceae) in Flora of North America and Jepson Manual, Flora of California: *Polygonum sawatchense* subsp. *oblivium*. *Polygonum sawatchense* is typified and its taxonomy and distribution in North America are discussed.

RESUMEN

Se describe y se ilustra una nueva subespecie de *Polygonum sawatchense* Small para los futuros tratamientos del género *Polygonum* (Polygonaceae) en la Flora de Norteamérica y el Jepson Manual, Flora de California: *Polygonum sawatchense* subsp *oblivium*. *Polygonum sawatchense* se ha tipificado y se discute su taxonomía y distribución en Norteamérica.

INTRODUCTION

Small (1893) described *Polygonum sawatchense* from some specimens collected by Katherine Brandegee in Sawatch Range, Colorado, U.S.A., and deposited in CAS. When Hickman (1984) proposed to treat this species at subspecific rank within *P. douglasii* Greene, he observed that these collections were presumably destroyed during the earthquake and fire of 1906. He did not propose a lectotype or neotype and instead adopted the epithet of the heterotypic *P. douglasii* var. *johnstonii* Munz, calling the subspecies *P. douglasii* subsp. *johnstonii* (Munz) J.C. Hickman (Hickman 1984). He thus cited the holotype of *P. douglasii* var. *johnstonii* when he made the new combination *P. douglasii* subsp. *johnstonii* (Hickman 1984). However, based on his annotations from various herbaria (e.g. CAS, DS, UC, RSA) later Hickman considered plants that agree morphologically with the type of *P. douglasii* subsp. *johnstonii* to be "intermediates between *P. douglasii* subsp. *douglasii* and subsp. *johnstonii*," whereas the type of *Polygonum douglasii* var. *johnstonii* published by Munz (1935) is actually within the range of variation of typical *P. sawatchense* Small. In fact, Hickman (1993) shifted the meaning of *P. douglasii* subsp. *johnstonii* to an undescribed taxon. During the preparation of the accounts of *Polygonum* s.str. for Flora of North

[1]Corresponding author.

America and the forthcoming revision of the Jepson Manual, Flora of California, it was concluded that *P. sawatchense* should be accepted at the specific rank. Plants that were referred to by Hickman (1993) as "*P. douglasii* subsp. *johnstonii*" are described here as a new subspecies, *P. sawatchense* subsp. *oblivium*.

MATERIAL AND METHODS

Descriptions and details of distribution of taxa are based on collections from: A, ALTA, CAS, DAO, DC, DS, GH, F, JEPS, LL, MT, MTMG, NY, OAC, POM, QFA, RSA, SASK, TEX, UBC, UC, USAS and US. Stem papillae are easily observed on young stems or toward apices of mature stems and branches, at magnifications higher than 50. Measurements of leaves, ocreae and petioles were made at the middle of the main stem. The state characters, "flowers closed" and "flowers wide-open" were observed on herbarium specimens. However, it should be noted that in fruit, flowers are always closed. Description of perianth refers to the fruiting perianth, which was measured from the joint with the pedicel. Pictures were taken with a Scanning Electron Microscope Hitachi S-570 at 15 KV. Samples were collected from herbarium specimens within the holdings of GH, NY and RSA; these collections were indicated with a "*" in the lists of representative specimens examined. Samples were coated with 30 nm gold using an Emitech K 550 Sputter Coater.

Typification of Polygonum sawatchense

A specimen collected by Brandegee from the Sawatch Range, Colorado is deposited in NY (00323810!), but it was not cited by Small (1893) in the protologue and, furthermore, it is damaged. A neotype is designated below from one of the specimens cited one year later by Small (1894) as "nearly like the original in every respect."

Taxonomy

Hickman (1984) proposed a new taxonomic concept for *P. douglasii* by including within it five other species: *P. sawatchense*, *P. spergulariaeforme* Meisn. ex Small, *P. majus* Meisn., *P. nuttallii* Small and *P. austiniae* Greene. Hickman (1984) justified these new combinations by the intermediate patterns of variation he observed between some of the taxa: "intermediates sometimes outnumber typical forms." For example, he reported such frequent intermediates between *P. douglasii* and *P. sawatchense* (Hickman 1984). However, even in this case Hickman admitted later that they "both may grow together without local intergradation" (Hickman 1993). We found that Hickman's intermediates (in herb.) are in most of the cases within the range of variation of each taxon, which has been poorly understood. *Polygonum sawatchense* is more variable than previously known and two subspecies, one of them formally undescribed, are recognized here. The two subspecies may partially intergrade in the areas of sympatry.

Polygonum sawatchense Small, Bull. Torrey Bot. Club 20:213, pl. 156. 1893. TYPE: U.S.A. Yellowstone Park, 1885, *T. Tweedy s.n.* (NEOTYPE, here designated: US!).

a. P. sawatchense subsp. sawatchense (Fig. 1a)

= *Polygonum douglasii* Greene var. *johnstonii* Munz, Man. So. Calif. Bot. 131:597. 1935; *P. douglasii* subsp. *johnstonii* (Munz) J.C. Hickman, Madroño 31:250. 1984.

Polygonum exile Eastw., Proc. Calif. Acad. Sci. Ser. 3, Bot. 2:286. 1902.

Polygonum triandrous Coolidge, Madroño 20:266. 1970.

Stems green to brownish, usually branched from base, 4–50 cm long, glabrous (Fig. 2a), with smooth faces and sometimes narrow winged angles. Leaves; ocreae glabrous; blades linear, narrow-oblong to oblanceolate, 15–45 × 2–8(–12) mm; margins usually revolute, glabrous (Fig. 2c); upper leaves abruptly reduced to scale-like bracts, or much longer than the flowers they subtend. Inflorescences axillary or of long, open spike-like racemes, 5–15 cm long; cymes (1–)2–4-flowered; bracts equalling, somewhat longer, or much longer than the flowers. Flowers closed; pedicels erect, 1–4 mm; perianth (2.5–)3–3.5 mm, the tube 25–40% of the perianth length, the tepals naviculate (Fig. 2e), greenish or reddish with white or pink borders, with midveins unbranched or with a few branches at base. Stamens 3–8; anthers pink to purple, 130–160 µm long. Achenes black, trigonous, 2.5–3 mm, ovate or elliptic, smooth.

Distribution and ecology.—CANADA: Alberta, Saskatchewan. U.S.A.: Arizona, California, Colorado, Idaho, Montana, Nevada, New Mexico, North Dakota, South Dakota, Utah, Washington, Wyoming. MEXICO: Baja California. It grows in dry meadows, pastures, sagebrush and forests on sandy, gravelly or rocky substrates. Flowering Jun–Aug.

It is important to emphasize that narrow-leaved plants regarded by Hickman as intermediates between *P. douglasii* subsp. *douglasii* and his "subsp. *johnstonii*," belong in fact to *P. sawatchense* subsp. *sawatchense*. Even with this narrow circumscription, *P. sawatchense* subsp. *sawatchense* is variable. "Typical" *P. sawatchense* plants described by Small from the Rocky Mountains, Colorado are relatively dwarf, 6–15 cm tall, dull green-brownish with persistent leaves that gradually transform into leaf-like bracts, 3–5 times longer than the flowers they subtend. Plants described as *P. douglasii* var. *johnstonii* by Munz from San Bernardino Mountains, California are taller, to 50 cm, with caducous green-glaucous, basal leaves, sharply differentiated from the bracts, which are equal to or up to 3 times as long as the flowers they subtend. However, we found a continuous transition between these two extremes, and a further subdivision of *P. sawatchense* subsp. *sawatchense* is apparently not possible. Collections of Patterson (1885) from the Rocky Mountains, near Golden, Colorado illustrate very well this transition. For example, *Patterson 131* (UC, NY) collected from elevations ranging from 3000 to 3300 m is "typical." Small himself observed that another collection (*Patterson 128*; NY, UC, US) from an elevation of 1800 m

b. Polygonum sawatchense subsp. **oblivium**, Costea & Tardif, subsp. nov. **(Fig. 1b).** TYPE: U.S.A. CALIFORNIA. Siskiyou Co.: Salmon Mountains, High Lake Basins in the vicinity of English Peak, Marble Mountain Wilderness Area, gully near meadow SE of Tom Taylor Cabin, elevation 6700 ft, 13 Aug 1967, *F.W. Oettinger 260* (HOLOTYPE: RSA).

Polygonum douglasii subsp. *johnstonii* auct

Polygono sawatchensi subsp. *sawatchense* affinis sed caulis scabri-papillosis et foliis oblongi-ellipticis vel ellipticis, marginibus papillosi-denticulatis differt.

Stems green, simple or with a few branches from base, 5–15(–25) cm long, papillose scaberulous on and between ribs; papillae white, patent, dense, conic-cylindrical, 90–150 µm long (Fig. 2b). Leaves; ocreae 4–10 mm, scaberulous, with the free part lacerate or disintegrating into a few fibers; blade elliptic to oblong-elliptic, gradually decreasing in size upwards and persistent at flowering-fruiting stage, 8–20(–25) × 5–10 mm, acute at both ends; margins plane, papillose-denticulate; papillae similar to those present on the stems (Fig. 2d). Inflorescences mostly axillary or if a terminal spiciform raceme present, then less than 5 cm long; cymes-1–3(–4)-flowered. At least some flowers wide-open; pedicels 1–3 mm. Perianth 3–4 mm, the tube 20–30% of the perianth length, tepals oblong-elliptic, cucullate, naviculate and overlapping (Fig. 2f), greenish-white or greenish-yellow (sometimes flushed with purple) with white borders the mid-veins greenish or brown, usually branched at base. Stamens 8; anthers pink to purple, rarely whitish, 130–200 µm. Achenes black, trigonous, 2.6–3.3 mm, elliptic to elliptic-ovate, smooth.

Distribution and ecology.—CANADA: British Columbia. U.S.A.: California, Idaho, Nevada, Oregon and Washington. It has the same ecology as subsp. *sawatchense*, but unlike the latter may also grow in shaded or moist places. Flowering Jun–Aug.

This taxon has been usually referred to as *P. douglasii* subsp. *johnstonii* (e.g.

by Hickman 1993). The protologue of *P. douglasii* var. *johnstonii* indicates only that it has erect pedicels, 1 mm long (Munz 1935). Hickman (1984) studied the holotype of *P. douglasii* var. *johnstonii* from RSA (*Munz & Johnston 8506*) when he included *P. sawatchense* within his new subspecies of *P. douglasii*. He noted: "the type shows several features of subsp. *douglasii* but it is closer to the extreme of subsp. *johnstonii* so the latter epithet can be retained at subspecific rank" (Hickman 1984). However, only almost 10 years later, in the Jepson Manual (1993) did it become apparent what Hickman understood by "subsp. *johnstonii*." He described this taxon as having "persistent leaves, all elliptic" (Hickman 1993). This intrigued us because Munz's holotype has caducous, narrow, oblong-lanceolate leaves. Even Munz specified later (Munz & Keck 1968) that, except for the erect and short pedicels, *P. douglasii* var. *johnstonii* is like *P. douglasii* (var. *douglasii*), namely with narrow, oblong-lanceolate leaves. Apparently, Hickman changed the original meaning of this name, from the plants of Munz, which are within the range of variation of typical *P. sawatchense*, to a taxon that has not been formally described. These plants are called here *P. sawatchense* subsp. *oblivium*. This confusion induced Hickman to consider plants of *P. douglasii* with broad leaves (var. *latifolium* Greene), as well as typical plants of *P. sawatchense*, to be intermediates "between subsp. *douglasii* and subsp. *johnstonii*" (Hickman, in herb.).

The stems of *Polygonum sawatchense* subsp. *oblivium* are scaberulous-papillose (Fig. 1b, 2b), the leaves are oblong-elliptic to elliptic (Fig. 1b), papillose-denticulate on the margins (Fig. 2 d) and the flowers, at least some of them, are open. *Polygonum sawatchense* subsp. *sawatchense* is entirely glabrous, the leaves are linear to oblanceolate (Fig. 1a, Fig. 2a, c), and flowers are normally closed. The tepal surface pattern of the two taxa is also different (Costea & Tardif, unpublished). Both subspecies occur in California, Idaho, Nevada and Washington. However, *P. sawatchense* subsp. *sawatchense* is more widely distributed, extending from Mexico, Arizona and New Mexico to Utah, Wyoming, Montana, South Dakota, North Dakota and Canada - Alberta and Saskatchewan. Although the two taxa are usually distinct, intermediate variation patterns may occur in the areas of sympatry, and this is why we treated them as subspecies. For example, glabrous plants with more or less broad and gradually decreasing leaves, as well as papillose-scaberulous plants with relatively narrow leaves, may be occasionally encountered.

Munz, who described *P. douglasii* var. *johnstonii* (1935), observed that this was different from *P. sawatchense* subsp. *oblivium*, but he usually identified the latter plants as *P. austiniae* (e.g. *Munz 18361*, RSA). *Polygonum sawatchense* subsp. *oblivium* differs from *P. austiniae* through its erect pedicels and much larger achenes. *Polygonum sawatchense* subsp. *oblivium* has also been frequently confused with *P. minimum*. They differ in respect to the morphology of leaves and ocreae, stems, size of fruiting perianth and achenes, as well as the pattern of

epicuticular wax sculpture of tepals (Costea & Tardif, unpublished). In particular, *P. minimum* has leaves that are hardly reduced distally, funnelform ocreae, 1–4 mm long, papillae on stems and ocreae are conical, short, with a swollen base, and flowers and achenes are usually much smaller.

TYPIFICATION AND NOMENCLATURAL HISTORY OF *TRACHELOSPERMUM DIFFORME* (APOCYNACEAE)

Alexander Krings

Herbarium, Department of Botany
North Carolina State University
Raleigh, NC 27695-7612, U.S.A.
Alexander_Krings@ncsu.edu

ABSTRACT

This study documents type specimens for names associated with the twining vine *Trachelospermum difforme*. Although not cited in the literature, a holotype of *Echites difformis* Walter was discovered in the Thomas Walter herbarium of the Natural History Museum, London. Types and nomenclatural history are discussed for other synonyms and combinations.

RESUMEN

Se documentan tipos para nombres asociados con la enredadera *Trachelospermum difforme*. Aunque no citado en la literatura, fue descubierto un holotipo en el herbario de Thomas Walter en el Museo de Historia Natural, Londres. Se dan tipos e historia de nombres para los sinónimos y combinaciones.

The twining vine *Trachelospermum difforme* (Walter) A. Gray (Apocynaceae) is native to the eastern United States and was first described as *Echites difformis* Walter in 1788. However, Walter did not indicate specimens he had studied. His herbarium is housed at the Natural History Museum (BM), London, and photographs thereof may be found in the collections of the Gray Herbarium (GH) at Harvard University. Walter's herbarium contains 122 sheets, a great many of which are plants of his *Flora Caroliniana* (Walter 1788; Stafleu & Cowan 1988). Although numerous authors proposed new combinations based on Walter's *Echites difformis*, none cited an appropriate type specimen. As typification is an ICBN requisite (Greuter et al. 2000), this study seeks to document types for names associated with the species *Trachelospermum difforme*.

In his treatment of *Forsteronia*, Alphonse de Candolle (1844) cites two specimens for the entity *Trachelospermum difforme*: "in Virginia infer. (Pursh) Carolina! et Mississippi (Torr.! in h. Boiss.)." However, John Torrey was not born until 1796 and Frederick Pursh visited North America for the first time in 1799—well after Walter's Flora had been published (Stafleu & Cowan 1983, 1986). For his new combination based on *Echites difformis*, John Miers (1878) cited a Florida specimen ("v.s. in herb. Mus. Brit. Florida (Chapman)"). However, this specimen also cannot be considered as Walter's type as it was collected by Alvan Chapman (1809–1899) in 1845, many years after Walter's death in 1789. Lacking further citation in the literature of potential types seen by Walter, a search of the Walter herbarium at BM was undertaken by the author. Fortunately, the

SIDA 20(4): 1641–1644. 2003

search revealed a specimen of the taxon (*Walter 215*)—which should thus be considered the holotype of *Echites differmis* Walter.

In 1803, André Michaux proposed the name *Echites puberula* in his *Flora Boreali Americana* for the taxon in question. Three specimens that can be considered types for this name reside at the Muséum National d'Histoire Naturelle (P) in Paris. One specimen exhibits flowers in bud and a handwritten note "*Foresteronia differmis* A. DC." Another specimen exhibits fully opened flowers (but no labels) and the last exhibits fruiting material. From Michaux's protologue it is clear that both flowering and fruiting materials were available to him at the time of description.

In 1817, Poiret published the name *Tabernaemontana populifolia* and indicated seeing a specimen in "herb. Desfont." Poiret's name has long been cited in synonymy with *Trachelospermum difforme*. However, Poiret's type at FI-W does not belong to *Trachelospermum* (stems stout; lamina decurrent onto petioles). Recent annotations suggest it belongs to *Logania populifolia* (Lam.) Leeuwenberg (see also Leeuwenberg 1991). A small sachet (5 cm × 5 cm) of likely the same material resides at P, but bears no indication of locality (Aymonin, per. comm.). As the type belongs to another taxon, *Tabernaemontana populifolia* Poir. is here excluded from synonymy with *Trachelospermum difforme* (Walt.) A. Gray.

Miers, in proposing a new combination based on Poiret's name (i.e., *Thyrsanthus populifolius* (Poir.) Miers., Apocyn. S. Amer. 99. 1878.), indicated seeing a specimen collected by "Marshal [sic]" from Georgia in "herb. Mus. Brit." This specimen is indeed *Trachelospermum difforme* (BM!) and not *Logania populifolia*, however Miers' combination cannot be applied to the former species as ICBN Art. 7.4 holds that new combinations, in all circumstances, are typified by the type of the basionym (Greuter et al. 2000).

In 1836, Rafinesque proposed the name *Echites salicifolia*. However, this name is a *nomen illegitum* since *Echites salicifolia* Willd. ex Roem. & Schult. (=*Allamanda cathartica* L., Apocynaceae) was validly published in 1819 (Systema Vegetabilium 4:796). No type specimen could be located for Rafinesque's name. Unfortunately, as Stuckey (1971) notes, Rafinesque's herbarium was partially destroyed by rats after his death and virtually all the remaining material was discarded by Elias Durand. *Echites salicifolia* Raf. is not listed among Rafinesque's North American vascular plants at PH (Stuckey 1971), nor are potential type specimens found in the collections of GH and NY. Inquires with P and DWC also provided no material.

TAXONOMIC SUMMARY

Trachelospermum difforme (Walter) A. Gray, Syn. Fl. N. Amer. 2:85. 1878. *Echites differmis* Walter, Fl. Carol. 98. 1788. *Forsteronia differmis* (Walter) A.DC., Prodr. 8:437. 1844. *Secondatia differmis* (Walter) Benth. & Hook.f., Gen. Pl. 2:710, 723. 1876.

nom. invalid. *Thyrsanthus difformis* (Walter) Miers, Apocyn. S. Amer. 99:1878. *Thyrsanthella difformis* (Walter) Pichon, Bull. Mus. Natl. Hist. Nat. ser. 2, 20:192. 1948. TYPE: *Walter 215* (HT:BM!).

Echites puberula Michx., Fl. Bor. Amer. 1:120. 1803. TYPE: *Michaux s.n.* [protologue: "*in sylvis Carolinae inferioris*"] (ST: P; IDC Fiche! [three specimens: one with flowers in bud, one with flowers, and one with fruits]).

Echites salicifolia Raf., New Fl. N. Amer. 4:59. 1838 ('1836'), nom. illeg.; non Willd. ex Roem. & Schult. 1819. TYPE: unknown.

ACKNOWLEDGMENTS

I thank the curators and staff of the following herbaria for their kind assistance: BM (particularly V. Noble), DWC, FI (particularly E. Luccioli for digitizing images of Poiret's type), GH, NY, P (particularly G.G. Aymonin), and PH; the staff of the NC State University, Duke University, and University of North Carolina Libraries; Paul Fantz; and Wendy Worley. K. Gandhi and J. Bauml provided thoughtful reviews of a previous version of this manuscript.

NEW NAMES AND NEW COMBINATIONS IN THE FLORA OF HISPANIOLA

Henri Alain Liogier

Botanical Research Institute of Texas
509 Pecan Street
Fort Worth, TX 76102-4060, U.S.A.

In revising the published Flora of Hispaniola (1981, 1989, 1994, 2000), I have found a need to make revisions in nomenclature of some taxa. Some names were antedated by previous publications, and this came to my attention when I was verifying publication dates through the W3TROPICOS (2003) database on the web page of the Missouri Botanical Garden.

The following changes are made to correct inadvertent errors I have made for lack of complete bibliographies in the past. I am very grateful to W3TROPICOS for enabling me to catch these errors. I also want to thank the Botanical Research Institute of Texas, for the use of its library and the facilities given to me for my research. The National Botanic Garden in Santo Domingo has a very good plant collecting program underway, along with a number of detailed florulas.

GLANDULARIA VERECUNDA (VERBENACEAE): SPECIES OR FRUIT-FORM?

B.L. Turner

University of Texas at Austin
Plant Resources Center
1 University Station F0404
Austin, TX 78712-0471, U.S.A.

In the most recent issue of Sida, Henrickson (2003) treated *Glandularia verecunda* Umber as a distinct species, this in sharp contrast to the present author's treatment of the taxon as but a fruit-form of *G. quadrangulata* (Heller) Umber (Turner 1999). My reason for this disposition followed several years of field work in which I could find no differences between the two hypothetical species except that of a terminal appendage on the apex of *G. verecunda*, this nicely illustrated by Henrickson's Fig. 1.

Glandularia verecunda was first proposed by Umber (1979), the species name said to be derived from the Latin word *verecundus* or "bashful," presumably in reference to the taxon's proclivity to go unnoticed, both in the herbarium and in the field. Indeed, Umber's description of the taxon nearly matches that of *G. quadrangulata*, except for the terminal appendage on the fruit. Turner (1999) clearly noted that Umber himself remarked that *G. verecunda* is "indistinguishable from *G. guadrangulata* except for the seeds," meaning the presence of an appendage on the nutlets.

Glandularia verecunda and G. quadrangulata are partially if not largely sympatric over most of their distributions (not "largely allopatric" as stated by Henrickson, his use of the term sympatric apparently restricted to *intrapopulational* occurrences of the two taxa).

After a discussion "Of the three nomenclatural possibilities: (1) being inconsequential forms of each other; (2) being geographical subunits of a species, i.e. subspecies or varieties of one species; or (3) being separate species that merely co-occur in some areas," Henrickson surmises that the two taxa are distinct species "that are very similar vegetatively but can co-occur without interbreeding as no intermediates have been found." Immediately thereafter, he concluded his discussion with a terse paragraph, as follows:

> "If there was evidence of interbreeding, they [sic] the two taxa could be recognized at the infraspecific level. But this does not exist. Therefore the two taxa will here be recognized as distinct species."

Henrickson comments further that "No plants have ever been discovered in nature with nutlets intermediate in structure between those of *G. quadrangulata and G. verecunda* ... Furthermore, no artificial hybridization has been done to

determine the condition that would be expressed in a hybrid." Needless to say, this same comment might be applied to most any albino form occurring in natural populations; nor does one spend much effort seeking out an intermediate plant to prove the point!

Fruit forms (or fruit polymorphism) in natural populations are relatively rare, but are relatively common in some groups such as, for example, the genus *Valerianella* (Valerianaceae). The interested reader is referred to the work of Ware (1983), who detailed numerous fruit forms in *Valerianella*, several of which had long been recognized as species. For those interested in the genetics of such fruit types, the work of Xena de Enrech and Mathez (1998) might be consulted.

Fruit forms also occur in other Texas plants, for example in the genus *Thelesperma* (Asteraceae). The species *T. curvicarpum* Metchert, first described in 1963 from Burnett and Coleman counties, Texas, was subsequently shown to be but a fruit-form (Greer 1997). And it is likely that my description of *Cynoglossum hintoniorum* Turner (Boraginaceae) amounts to no more than a fruit-form of the widely distributed *C. amabile* Stapf & Drumm. (Turner 1995).

Finally, it should be reemphasized that I have called to the fore in the above-mentioned publication several populations of *G. quadrangularis* in which appendaged and nonappendaged fruits occur intermixed. The two forms can be separated only by the appendages on their nutlets, but I have no trepidation in recognizing this fruit-form as a named taxon, as follows:

Glandularia quadrangulata forma **albida** (Moldenke) B.L. Turner, comb. nov.
BASIONYM: *Verbena pumila* forma *albida* Moldenke, Phytologia 9:188. 1963.

= *Glandularia verecunda* Umber

Umber (1979 treated the forma as a synonym of his concept of *G. verecunda*. It is unfortunate to have to take up the name "albida" for this fruit-form, but the Code of Botanical Nomenclature mandates use of the earliest name in rank as having priority.

cbenitez@telcel.net.ve berles@cantv.net

RESUMEN

Se estudian y describen las características de la epidermis foliar en ambas superficies, de los taxones del Grupo de especies *Solanum sessile*, representados en Venezuela a saber: *Solanum chlamydogynum* Bitter, *S. obovalifolium* Benítez, *S. oppositifolium* Ruiz & Pav., *S. sessile* Ruiz & Pav., *S. triste* Jacq. y *S. turgidum* S. Knapp. Se utilizaron segmentos de aproximadamente 1 cm^2 de la porción media de hojas secas (especimenes de herbario) o frescas y fijadas en FAA al 70%. Fueron aplicadas técnicas anatómicas convencionales para macerado y tinción. Se evalúan las siguientes variables: presencia, tipo, dimensiones y ubicación de estomas; presencia, tipo, longitud, ubicación y densidad de tricomas; forma y grosor de la pared de las células epidérmicas normales e índice estomático. Los resultados muestran diferencias en algunas de las características anatómicas consideradas, especialmente las referidas a los tipos tricomáticos y a la ubicación de estomas. Dichos resultados se comparan y han permitido la separación de las especies mediante una clave.

ABSTRACT

Epidermal characteristics of leaf blades were studied and described from taxa belonging to the species Group containing *Solanum sessile* represented in Venezuela by the following species: *Solanum chlamydogynum* Bitter, *S. obovalifolium* Benítez, *S. oppositifolium* Ruiz & Pav., *S. sessile* Ruiz & Pav., *S. triste* Jacq. and *S. turgidum* S. Knapp. Middle portions of leaf blades were sampled from herbarium specimens and from fresh plant material fixed in FAA 70%. Conventional anatomical procedures for macerations and staining were used. The following criteria were evaluated: presence, type, dimension and location of stomata; presence, type, length, location and density of trichomes; shape and thickness of the wall of normal epidermal cells, and stomatal index. Results show there are differences in some anatomical characteristics between species especially with regards to trichome types and the location of stomata. These characteristics can be used to identify collections of *Solanum* to the species level. A key to the species of *Solanum* section *Geminata* using these characters is presented.

La Sección *Geminata* del género *Solanum* con 122 especies acomodadas en 16 grupos (Knapp 2002), es una de las secciones dentro del género con mayor número de especies, localizadas principalmente en regiones tropicales de América del Sur y con unas pocas especies representadas en el Viejo Mundo; en Venezuela están presentes 34 especies constituyendo el 23% del total mundial

SIDA 20(4): 1651–1661. 2003

y el 32% del total de especies del género *Solanum* en Venezuela (105). Dichas especies estan ampliamente distribuídas, principalmente en selvas húmedas primarias de los pisos meso y microtémicos y en selvas semideciduas y secundarias de los pisos macrotérmicos (Knapp 2002).

Las especies que conforman esta sección exhiben caracteres morfológicos, que en términos generales pueden ser utilizados para el reconocimiento de las mismas como miembros de la sección; tales son su condición de arbustos o árboles, inflorescencias características del tipo cimas helicoidales naciendo opuestas o alternas a una hoja que puede ser geminada o no. La importancia taxonómica de caracteres anatómicos foliares ha sido ampliamente reconocida por muchos investigadores (Solereder 1908; Metcalfe y Chalk 1950; Carlquist y Holt 1961).

Entre dichos caracteres, los estomas que varían en forma, número, orientación y arreglo de las células subsidiarias que los rodean, han desempeñado un papel importante en los procesos evolutivos de las especies vegetales, desde el punto de vista anatómico y taxonómico, lo cual ha justificado su estudio por líneas diferentes y en diversas familias, como lo indicado por Ahmad (1964) quien realizando estudios epidérmicos en 28 especies pertenecientes al género *Solanum*, encontró mayor frecuencia estomática en especies de dicho género comparado con otros géneros, reportando anomalías estomáticas en algunas especies tales como en: *S. macranthum* Dunal, *Solanum nigrum* L., y *Solanum decorticans* Sendtn.

En 1979 Bessis y Guyot estudiaron estomas en miembros de algunas tribus de las Solanaceae, concluyendo que la distribución de tipos de estomas puede ser utilizada para establecer divisiones sistemáticas y sugerir relaciones filogenéticas entre los miembros de dicha familia. Rashib y Beg (1989) elaboraron una clave foliar, como herramienta taxonómica, para algunas especies de la familia Solanaceae, en la que incluyeron características de estomas y tricomas. También los tipos tricomáticos así como su densidad y frecuencia, han sido de alto valor diagnóstico para la definición de las especies, carácter que ha sustentado la clasificación infragenérica dentro de *Solanum* establecida por Seithe (1962, 1979). Dada la utilidad de los caracteres anátomicos foliares como rasgos de valor diagnóstico, en el presente trabajo se estudian y describen las características de la epidermis foliar en ambas superficies, de los taxones del Grupo de especies *Solanum sessile* representados en Venezuela a saber *Solanum chlamydogynum* Bitter, *S. obovalifolium* Benítez, *S. oppositifolium* Ruiz & Pav., *S. sessile* Ruiz & Pav., *S. triste* Jacq. y *S. turgidum* S. Knapp. Los caracteres evaluados y los resultados obtenidos se comparan intentando extraer información anatómica destacable entre las especies.

MATERIALES Y METODO

El material estudiado procede de colecciones de herbario y de aquel fresco fijado

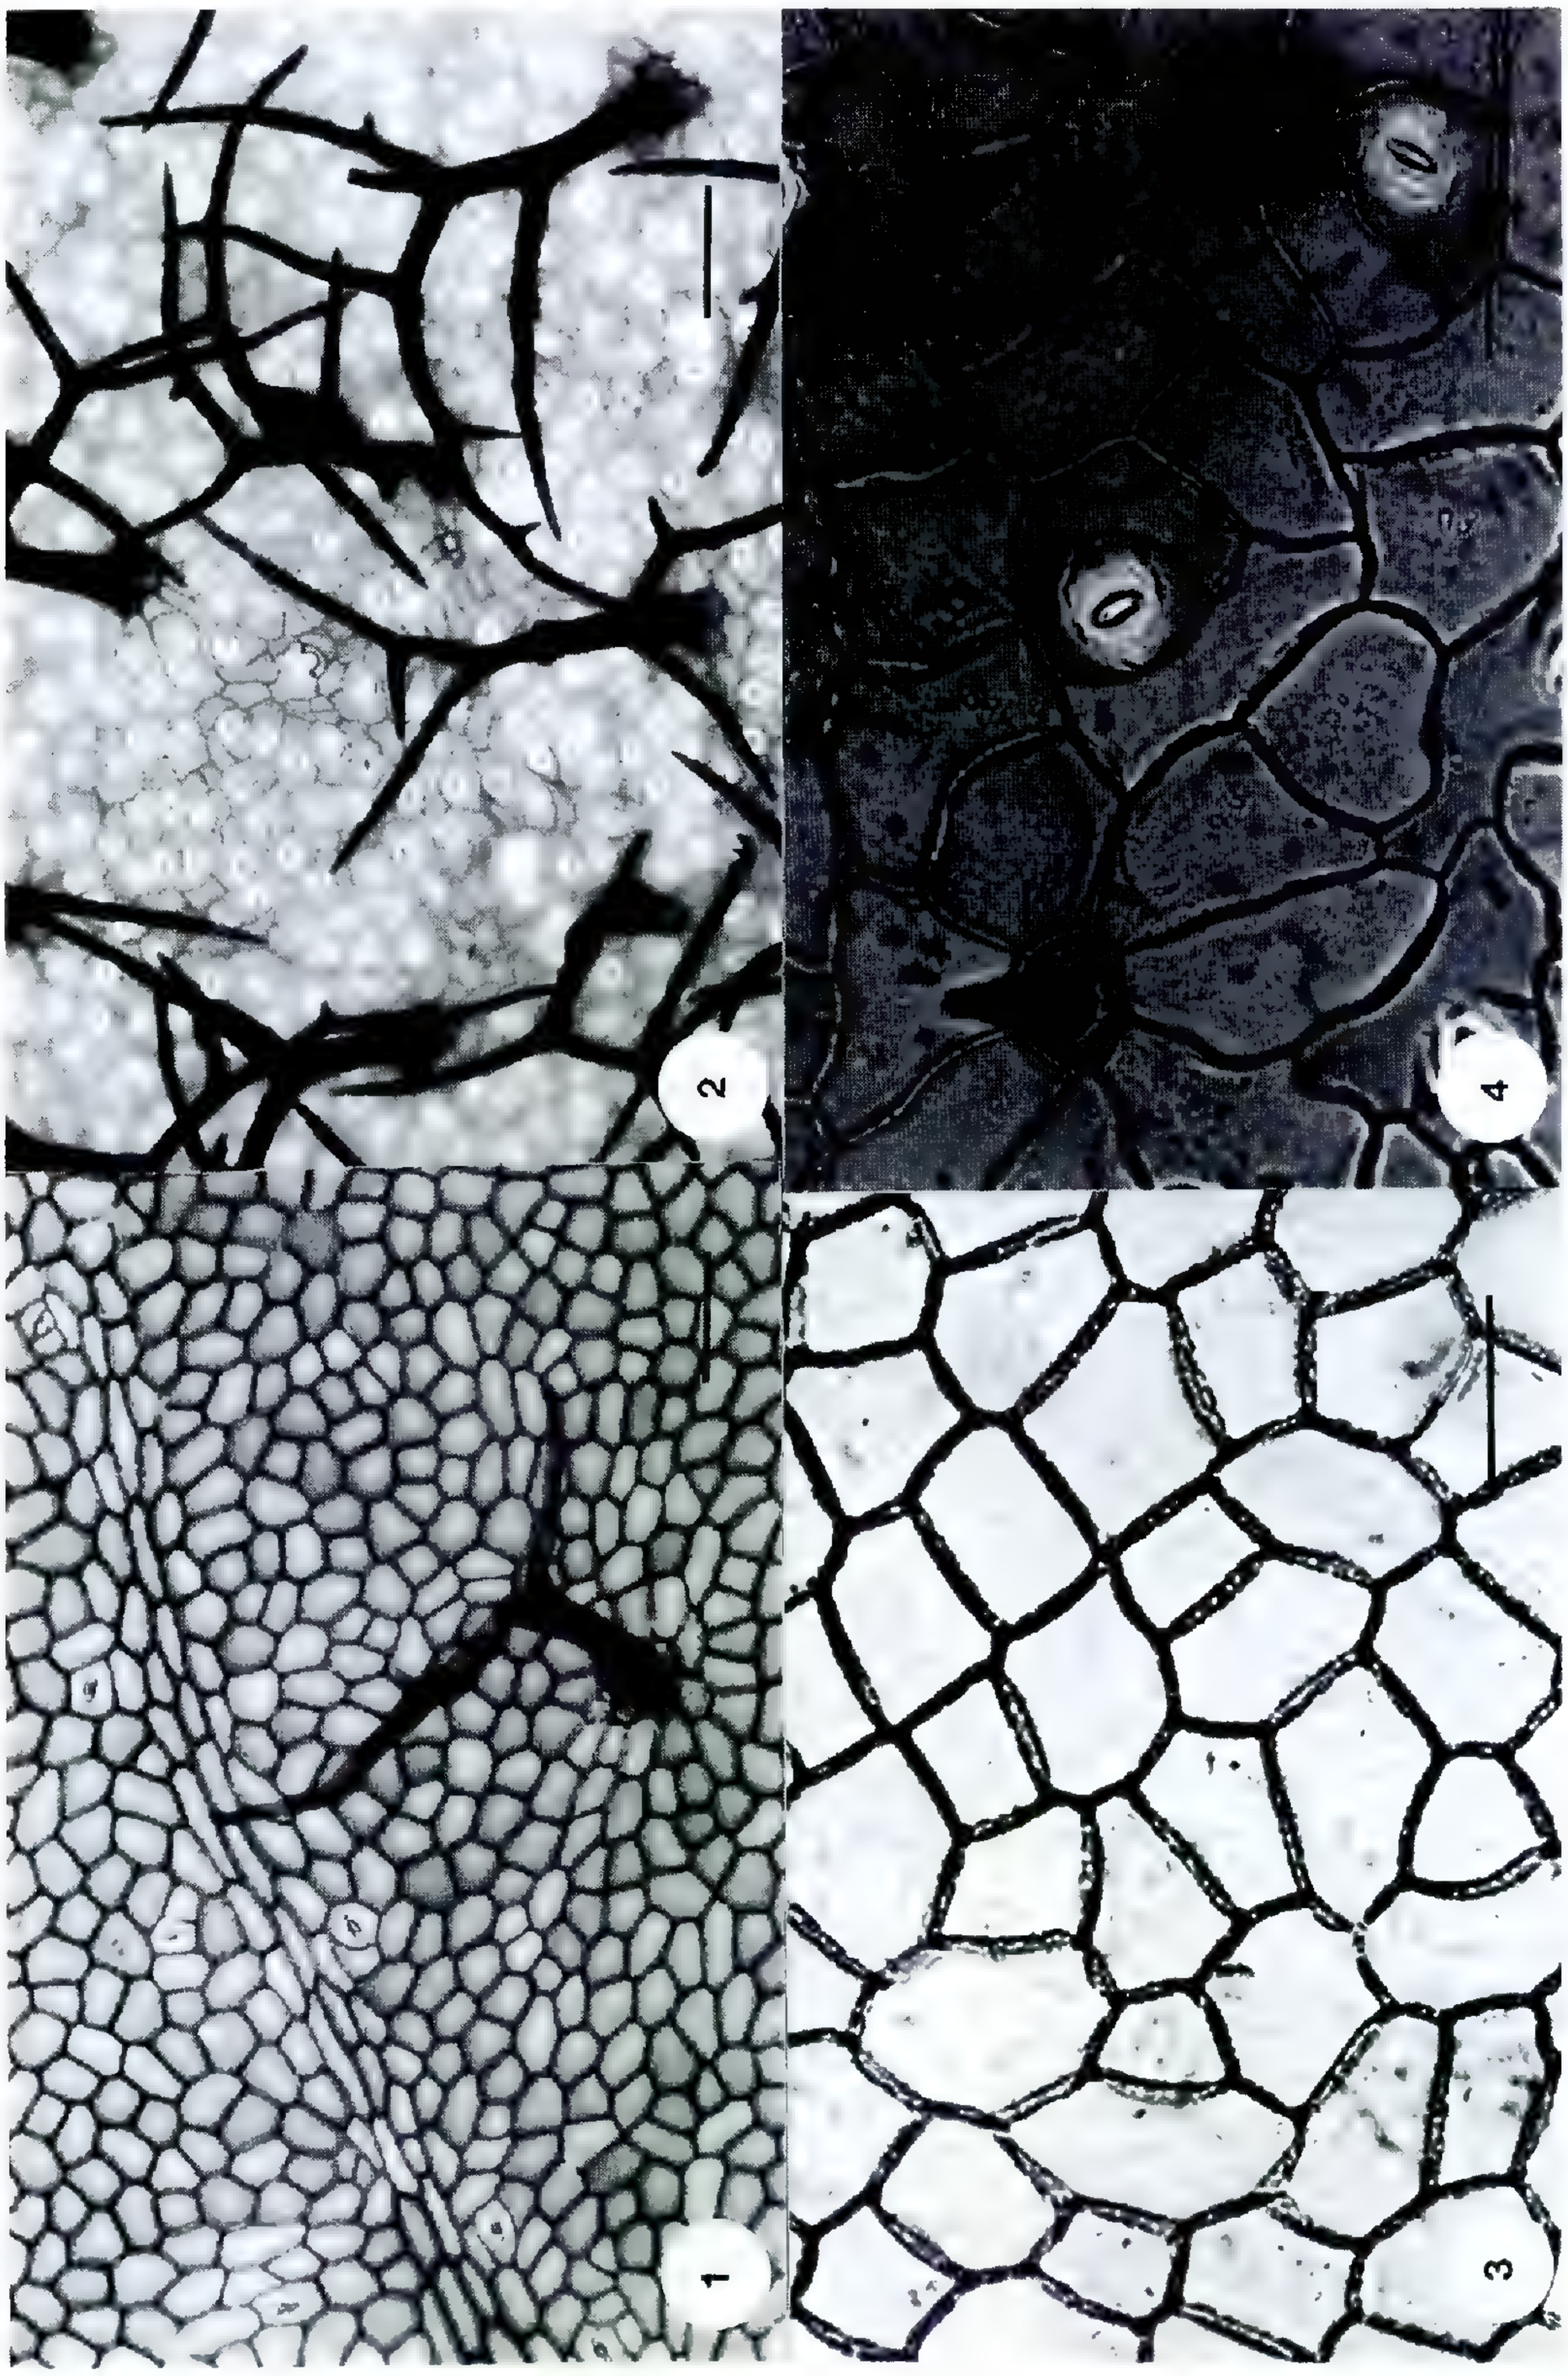
en FAA, según como se enumera en el Anexo 1. Se utilizaron segmentos de aproximadamente 1 cm^2 de la porción media de hojas pertenecientes a exsiccatas del Herbario Victor Manuel Badillo, Universidad Central de Venezuela (MY) o fijadas directamente en FAA al 70% (Formalina, ácido acético glacial, etanol 70%). En el primer caso, previo al estudio anatómico, las secciones de hoja fueron hidratadas sumergiéndolas en agua hirviente por 5-10 min. Para estudiar las características de la epidermis foliar, se realizaron macerados de la porción media de la lámina, colocando segmentos de aproximadamente 1 cm^2 (que incluyeran nervaduras) en una solución de hipoclorito de sodio 5,25% (cloro comercial) o en ácido nítrico 5%–ácido crómico 5% (1:1), en una estufa a 56–58° C. Luego se realizó un lavado profuso de la epidermis con agua destilada y se tiñó con azul de toluidina acuosa 0.5%, para finalmente montarla en agua-glicerina (1:1).Las láminas se observaron y fotografiaron con un microscopio binocular marca Leitz. Además, se realizaron algunas mediciones con la ayuda de un ocular micrometrado. La caracterización cualitativa y cuantitativa se ha obtenido mediante el análisis de las siguientes variables: Presencia, tipo, dimensiones y ubicación de estomas; presencia, tipo, longitud, ubicación y densidad de tricomas; forma y grosor de la pared de las células epidérmicas normales, etc. Además se determinó el índice estomático (I.E) mediante la siguiente formula establecida por Salisbury (1927)

$$I.E = \frac{\text{n° de estomas (S)}}{\text{n° de estomas (S)} + \text{n° de células epidérmicas (E)}} \times 100$$

RESULTADOS

Solanum chlamydogynum Bitter

Las células de la epidermis adaxial tienen contornos poligonales (Fig. 1) y paredes celulares ligeramente engrosadas, mientras que las de la epidermis abaxial poseen contornos poligonales a ligeramente ondulados y paredes delgadas (Fig. 2). Hoja anfiestomática; estomas de la epidermis adaxial principalmente del tipo anisocíticos (largo 25,03 µm y ancho 14,67 µm), ubicados próximos y sobre las nervaduras (Fig. 1), aunque pueden aparecer algunos aislados en la lámina. En la epidermis abaxial los estomas son con mayor frecuencia anisocíticos (I.E.= 19,78–22,51); largo 19,27–23,2 µm y ancho 14,83–17,2 µm). Presencia de tricomas protectores y glandulares en ambas epidermis. En la epidermis adaxial, los tricomas protectores aparecen simples y ramificados sobre la lámina y nervaduras en muy baja densidad (0,22/mm^2); los protectores simples son multicelulares uniseriados con ápice agudo y con longitud y número variable de células. Los protectores ramificados (multicelulares) en su mayoría tienen dos ramas que emergen al mismo nivel (una más desarrollada que la otra), aunque también se observan con mayor cantidad de ramas. En la epidermis



Anexo 1. Relación del material garante utilizado para el estudio anatómico.

Colector	N° colección y herbario de depósito	Especie	Localización geográfica	Condición del Material
Ruiz Zapata, Thirza. et al.	*4568* MY	*S. chlamydogynum*	Edo. Aragua- Municipio Tovar. Selva nublada	De herbario
Benítez de Rojas C. E. et al.	*6193* MY	*S. chlamydogynum*	Edo. Aragua- Municipio Tovar. Selva nublada	FAA 70%

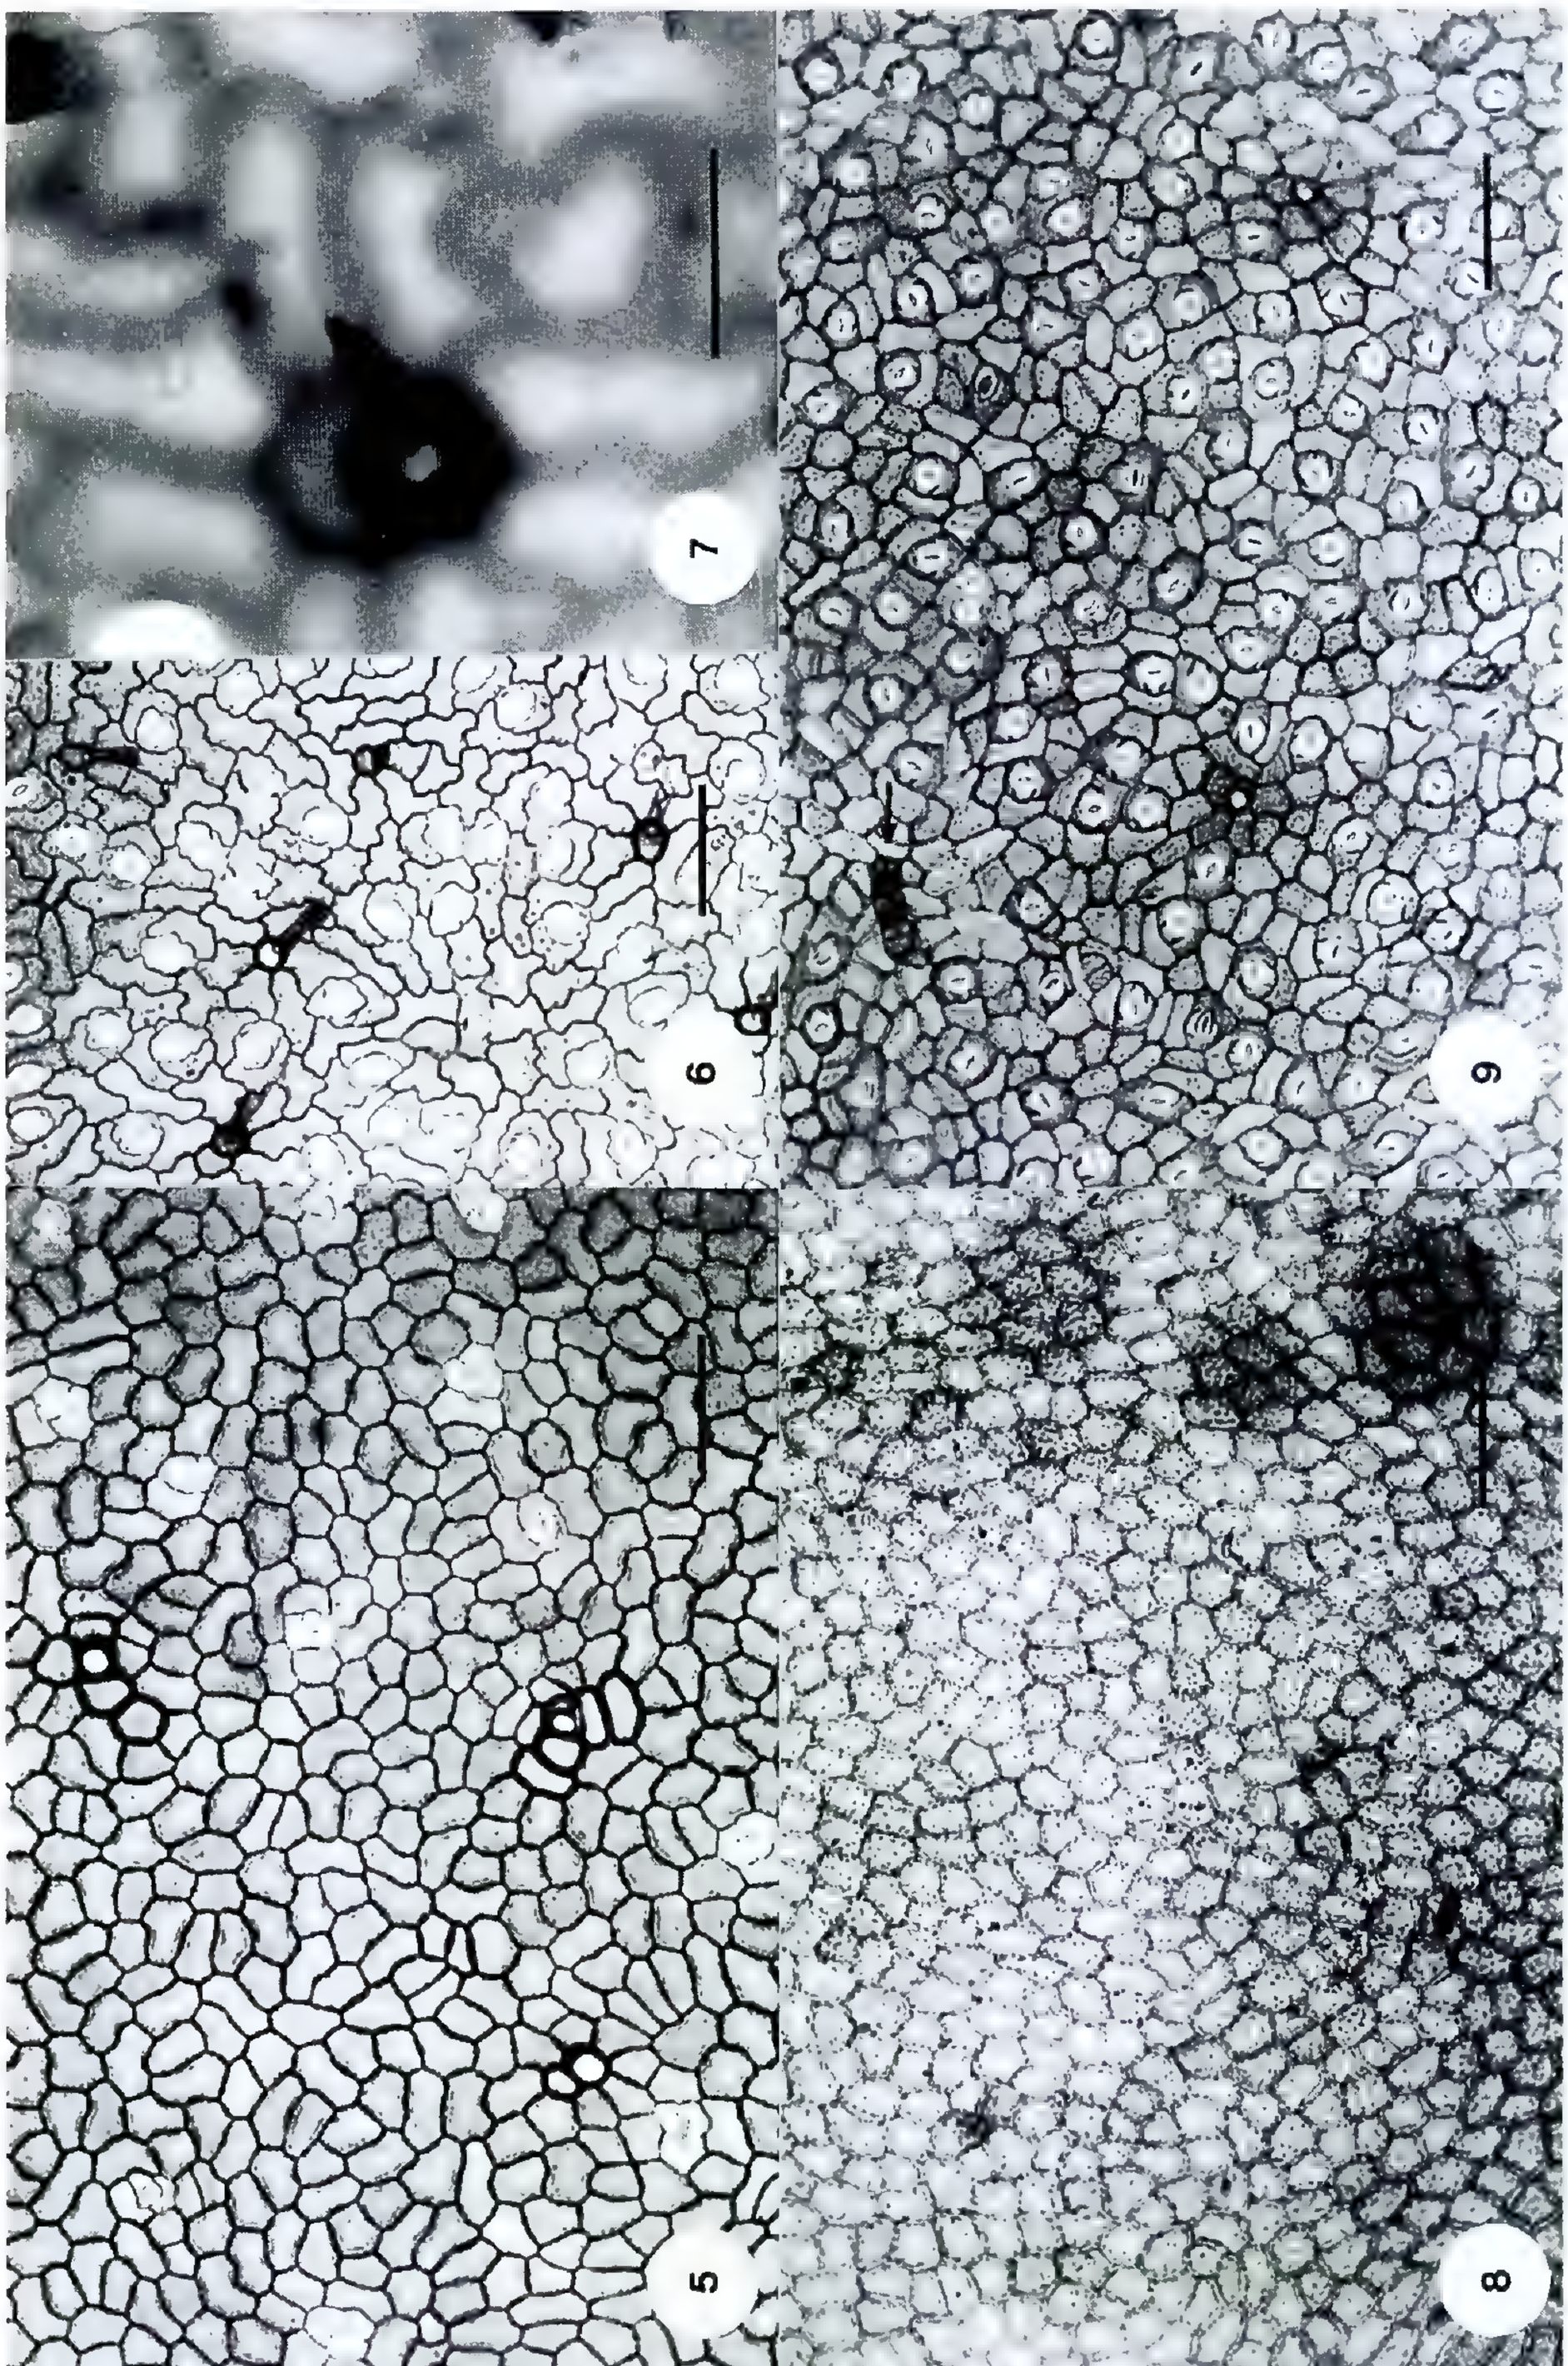
Knapp, S. et al.	*6763* MY	*S. turgidum*	Edo. Sucre-Península de Paria. Selva nublada	De herbario

abaxial, los tricomas protectores son todos multicelulares ramificados (Fig. 2) y se encuentran en una alta densidad sobre lámina y nervaduras (8,84–15,94/ mm^2); los mismos son de mayor tamaño que los de la epidermis superior y generalmente tienen dos ramas principales que emergen a un mismo nivel, las que luego se ramifican en un número variable de ramas de orden mayor (Fig. 2). Los tricomas glandulares en las dos epidermis son multicelulares simples (D adaxial= 2,39/ m^2; D abaxial= 1,47–2,78/ mm^2), no distinguiéndose claramente el número de células que los conforman.

Solanum obovalifolium Benítez

La epidermis adaxial presenta células con contornos poligonales, de paredes ligeramente engrosadas (Fig. 3), mientras que la abaxial está formada por células de paredes ligeramente onduladas y más delgadas. Hoja hipostomática (I.E.= 7,73–12,5); estomas con mayor frecuencia del tipo anisocíticos, aunque también se observan diacíticos (largo 19,5–20,1 µm y ancho 16,4–16,5 µm). En la epidermis adaxial se observan tricomas glandulares. En la epidermis abaxial están presentes tricomas protectores y glandulares, con una densidad de 3,27 y 4,75–7,2/ mm^2 respectivamente. Los primeros son simples, cortos y unicelulares (Fig. 4) y los segundos son simples, cortos, multicelulares uniseriados; sin embargo, no fue posible distinguir el número de células que lo conforman.



FIGS. 1–4. *Solanum chlamydogynum* **Figs. 1–2. 1.** Epidermis adaxial 100×. Obsérvese estomas próximos a las nervaduras, forma de las células epidérmicas normales y tricoma protector ramificado. **2.** Epidermis abaxial 100×. Véase tricomas protectores ramificados y forma de las células epidérmicas normales. *Solanum obovalifolium* **Figs. 3–4. 3.** Epidermis adaxial 400×. **4.** Epdermis abaxial 400×. Nótese tricoma protector simple unicelular. Barra de escala: Figs. 1–2 = 100 μm; Figs. 3–4 = 10 μm

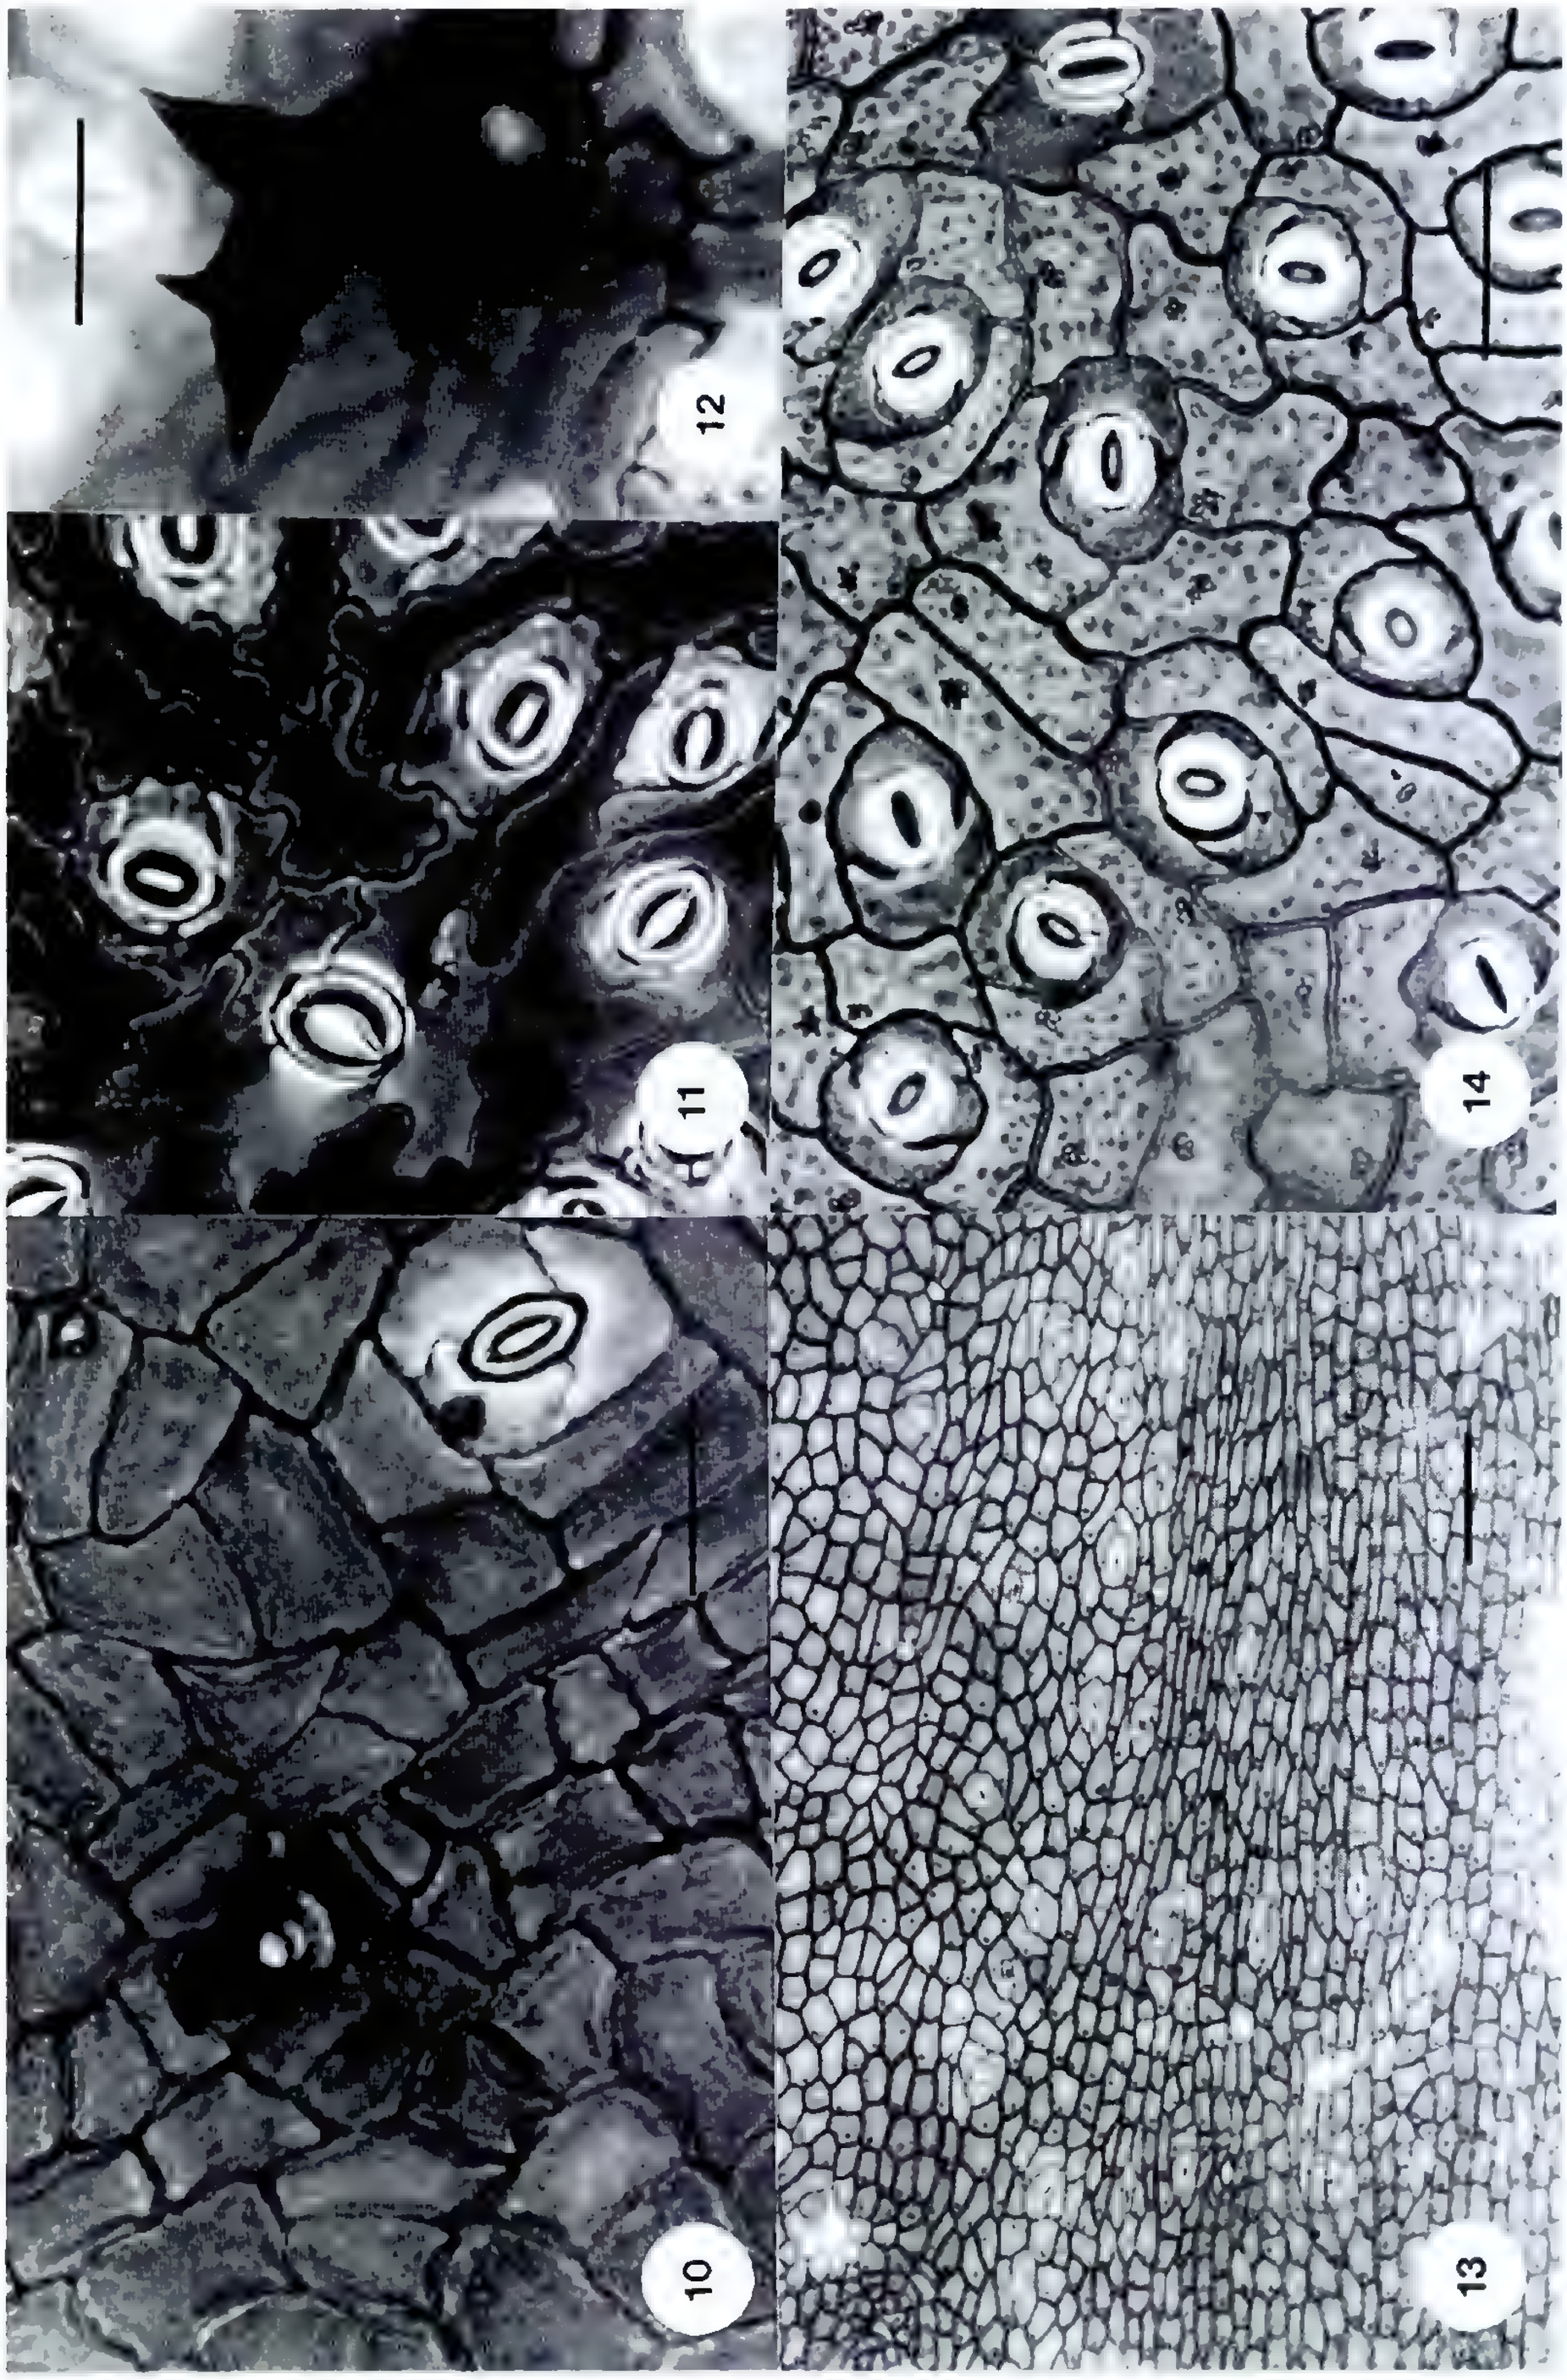
Ha sido indicado (Metcalfe y Chalk 1979), que el tricoma glandular es de naturaleza delicada, por lo que éstos son mejor detallados en material vivo o en especímenes tratados mediante secado por punto crítico.

Solanum oppositifolium Ruiz & Pav.
La epidermis adaxial presenta células epidérmicas normales con contornos poligonales a ligeramente ondulados y paredes celulares ligeramente engrosadas, mientras que la epidermis abaxial está formada por células con contornos ondulados y paredes relativamente delgadas. Hoja anfiestomática (I.E. superior 4,01; I.E. inferior 13,69); estomas del tipo anisocíticos en ambas epidermis (Fig. 5), siendo de largo 25,37 µm y ancho 15 µm en epidermis adaxial y de largo 24,37 µm y ancho 18,5 µm en la epidermis abaxial. Presencia de tricomas en ambas epidermis. En la superior todos se encuentran desprendidos, observándose únicamente las células basales (D= 0,83/ mm^2), por lo que se hace necesario repetir el procedimiento con una maceración más suave. Sobre las nervaduras se observan tricomas protectores simples, cortos y unicelulares. En la epidermis inferior se encuentran en mayor frecuencia tricomas glandulares alargados, de forma columnar, ubicados en toda la lámina (D=2,43/ mm^2) y sobre nervaduras; la parte inferior de este tricoma se tiñe intensamente con el azul de toluidina (Figs. 6,7). Ubicados principalmente sobre las nervaduras o próximos a ellas, se encuentran tricomas protectores cortos unicelulares, aunque en ocasiones pueden observarse sobre la lámina.

Solanum sessile Ruiz & Pav.
La epidermis adaxial está constituida por células de contornos poligonales y paredes celulares relativamente gruesas (Fig. 8), mientras que la abaxial tiene células epidérmicas normales con contornos poligonales y paredes ligeramente engrosadas, pero más delgadas que la epidermis superior (Fig. 9). Ambas epidermis presentan ornamentaciones a manera de papilas en la cutícula, siendo éstas con mejor definición en la epidermis superior (Fig. 8). Hoja anfiestomática; estomas de la epidermis adaxial únicamente presentes en muy baja frecuencia sobre las nervaduras principales o muy cerca de éstas (largo 29,67 µm y ancho 11,78 µm). Estomas de la epidermis abaxial principalmente del tipo anisocítico (Fig. 9) (I.E: 13,37; largo 23,1 µm y ancho 14,6 µm). Presencia de tricomas glandulares simples, multicelulares uniseriados, robustos, ubicados sobre la lámina y nervaduras de ambas epidermis (Fig. 9) (D adaxial =0,82/ mm^2 y D abaxial =4,4/ mm^2).

Solanum triste Jacq.
Células epidérmicas normales, de la epidermis adaxial, con contornos ligeramente ondulados y paredes relativamente delgadas. En la epidermis abaxial, las células tienen contornos ondulados y paredes delgadas (Fig. 11). Hoja anfiestomática; epidermis superior con estomas principalmente anisocíticos

FIGS. 5–9. *Solanum oppositifolium* **Figs. 5–7. 5.** Epidermis adaxial 100×. Nótese la presencia de estomas en la lámina. **6.** Epidermis abaxial 100×. Vista general. **7.** Detalle de tricoma protector simple unicelular 400×. *Solanum sessile* **Figs. 8–9. 8.** Epidermis adaxial 100×. **9.** Epidermis abaxial 100×. Nótese el tricoma glandular simple (indicado con flecha). Barra de escala: Figs. 5–6, 8–9= 100 μm; Fig. 7=10 μm



próximos a las nervaduras (Fig. 10) (largo 22,77 µm y ancho 15,07 µm) y epidermis inferior con estomas en su mayoría anisocíticos (Fig. 11) (largo 24,67 µm y ancho 18,43 µm) ubicados en la lámina (I. E. = 14,73). Tricomas protectores y glandulares presentes en ambas epidermis sobre la lámina y nervaduras. Los primeros son de dos tipos, simples cortos, multicelulares uniseriados (Fig. 10 y 12) y ramificados cortos (multicelulares, con ramas cortas cercanas a la base), siendo este último tipo de tricoma más ramificado en la epidermis inferior (Fig. 12). La densidad de los tricomas protectores fue de 6,08/mm^2 en la superficie adaxial y 13/ mm^2 en la superficie abaxial. Los tricomas glandulares son simples cortos, multicelulares uniseriados (D=1,26/ mm^2 en ambas epidermis).

Solanum turgidum S. Knapp

Células epidérmicas normales de la epidermis adaxial con contornos poligonales a ligeramente ondulados y paredes relativamente delgadas (Fig. 13), mientras que las de la epidermis inferior tienen contornos medianamente ondulados y paredes delgadas (Fig. 14). Hoja anfiestomática; estomas principalmente del tipo anisocítico, los de la epidermis adaxial ubicados próximos o sobre las nervaduras (Fig. 13) (largo 20,53 µm y ancho 13,3 µm), muy aisladamente se encuentran estomas dispersos sobre la lámina (Fig. 13). Los estomas de la epidermis abaxial se encuentran en mediana densidad sobre toda la lámina (Fig. 14) (I.E. 11,37; largo 19,57 µm y ancho 14,8 µm). Presencia de tricomas glandulares en ambas epidermis. En la superior, los mismos se encuentran colapsados, dispersos en toda la lámina (D=0,33/ mm^2). En la cara abaxial se observan constituidos por pie unicelular y cabeza formada por varias células (D=1,1/mm^2).En esta misma epidermis, sobre las nervaduras principales se observan tricomas protectores simples, cortos unicelulares. El pie unicelular del tricoma glandular se tiñe más intensamente con el colorante, lo que dificulta su observación.

CLAVE DE LAS ESPECIES

1. Tricomas únicamente glandulares _____ **Solanum sessile**
1. Tricomas protectores y glandulares
   2. Tricomas protectores siempre simples y cortos en la epidermis abaxial.
      3. Hoja hipoestomática _____ **Solanum obovalifolium**
      3. Hoja anfiestomática.
         4. Estomas en la epidermis adaxial ubicados en toda la lámina _____ **Solanum oppositifolium**
         4. Estomas de la epidermis adaxial sólo próximos a/o sobre las nervaduras _____ **Solanum turgidum**
   2. Tricomas protectores ramificados, excepcionalmente simples en la epidermis abaxial.
      5. Tricomas con ramas cortas. Paredes ce ulares onduladas en la epidermis abaxial _____ **Solanum triste**
      5. Tricomas con ramas largas. Paredes celulares poligonales a ligeramente onduladas en la epidermis abaxial _____ **Solanum chlamydogynum**

CONCLUSIONES

Rasgos del sistema dérmico representan caracteres útiles para la caracterización de las hojas en especies de *Solanum* sección *Geminata*, pudiendo ser de ayuda en la identificación de especies, lo cual ha sido indicado para otros géneros de Solanaceae (De Pasquale et al. 1991). El tipo de hoja según la ubicación de los estomas en ambas epidermis además de su distribución bien sea en la lámina o cerca de las nervaduras, representan caracteres de valor diagnóstico para las especies estudiadas. Respecto a la ubicación de los estomas, este rasgo permitió diferenciar las especies, no así el tipo de estoma ya que se evidenció similitud en todas las especies estudiadas. Los tricomas hasta ahora observados, básicamente protectores, son de valor para la diagnosis de las especies, carácter que ha sustentado la clasificación infragenérica dentro de *Solanum* (Seithe 1962, 1979). Aunque la mayoría de los tricomas glandulares se colapsan con la metodología utilizada en este estudio, no se consideró realizar un examen más detallado de ellos, ya que vistos al microscopio óptico son muy similares en todas las especies. Caracteres cuantitativos como densidad y longitud de tricomas reflejan variación condicionada por el ambiente y edad de la planta y raramente pueden ser usados para diferenciaciones taxonómicas (Metcalfe y Chalk 1950); por lo que dichos caracteres se han considerado como rasgos complementarios a la caracterización de las especies. El reconocimiento anatómico de la epidermis foliar como una fuente de evidencias taxonómicas ha permitido separar las especies mediante una clave.

JOHN and MARGARET CANNON. 2003. **Dye Plants and Dying.** (ISBN 0-88192-572-1, pbk.). Timber Press, Inc. 133 S.W. Second Ave, Suite 450, Portland, OR 97204-3527, U.S.A. (Orders: www.timberpress.com, mail@timberpress.com, 503-227-2878, 1-800-327-5680, 503-227-3070 fax). $19.95, 129 pp., 48 color paintings, 7 3/16 × 9 3/4".

This is a lovely book deserving of a readership beyond those mainly concerned with the fiber arts. For the historian and ethno-botanist the use of plants for color arose in the far distant past. For the botanical novice, the simple descriptions of the plants and the glossary and checklist of scientific names offer a good introduction to the science. There is material for the conservationist and the biochemist. For the art lover, the plates themselves make the book a delight

This combination of art and science makes this book important. It offers exact instructions for craft dyers and accurate botanical information about the plant sources of the coloring material. The illustrations are accurate and beautiful The color samples and mordant symbols are incorporated into the design of the plate so as to make a pleasing whole. This is an excellent book.

It covers a wide range of natural plant dyes and provides accurate botanical information about each plant. *Ruth Ginsburg, Botanical Research Institute of Texas, Fort Worth, TX, 76102-4060, U.S.A*

DOCUMENTED CHROMOSOME NUMBERS. 2003: 2. CHROMOSOME NUMBERS OF THE RARE TEXAS SPECIES, *ARIDA BLEPHAROPHYLLA* AND *A. MATTTURNERI* (ASTERACEAE: ASTEREAE)

A. Michael Powell

Biology Department
Sul Ross State University
Alpine, TX 79832, U.S.A.

Meiotic chromosome counts for the exceedingly rare Texas species, *Arida blepharophylla* (A. Gray) Morgan & Hartman and *A. mattturneri* B.L. Turner & Nesom (cf. description in this issue, p. 1418) are reported, both being diploid with $2n = 5$ pairs. The two taxa were found growing together or near each other in 'Blumberg Canyon', ca. 2 mi NNW of Ruidosa, Presidio Co., Texas.

Vouchers for the collections: ***Arida mattturneri***, *Matt Turner 100* (NY, SRSC, TEX); ***Arida blepharophylla***, *B.L. Turner 23-91* (SRSC, TEX).

Arida blepharophylla (= *Machaeranthera gypsitherma* Nesom, Vorobik & Hartman) was also previously counted as diploid ($2n = 5$ pairs) from a population in the state of Chihuahua, Mexico (Nesom et al. 1990). Free hand drawings of the chromosomes, from buds collected on 28 Aug 2003 by B.L Turner, are illustrated in Fig. 1.

Fig 1. Meiotic chromosomes of *Arida mattturneri* (left side, 5 bivalents at metaphase 1); and *A. blepharophylla* (5 bivalents and 3 centric fragments, at diakinesis)

RESUMEN

Se analizan algunos aspectos de la ecología, distribución y estado de conservación de *Mammillaria theresae* Cutak (Cactaceae), una especie endémica a una pequeña área de la Sierra de Coneto, localizada en el centro del estado de Durango (México) al oriente de la Sierra Madre Occidental y en el límite occidental del Desierto Chihuahuense. Por su condición de serranía aislada, la Sierra de Coneto es de interés ecológico y fitogeográfico; es la única localidad conocida para *M. theresae* y para un género recientemente descrito (*Megacorax*, Onagraceae). *Mammillaria theresae* es altamente apreciada por coleccionistas de especies exóticas; se conoce localmente con los nombres de peyote y peyotillo, y su población está siendo mermada debido a la ampliación de un camino. Se evaluó el estado actual de la población de *M. theresae* mediante muestreos de vegetación y monitoreo de 126 individuos en siete sitios. La especie crece en una superficie de 1.7 ha en manchones distribuidos en un área de 2.5 km^2, principalmente sobre sustrato rocoso. Debido a su distribución restringida, tamaño de población y disturbio y fragmentación de su hábitat, *M. theresae* califica en la categoría de en peligro de extinción. La información generada puede ser aplicada en el diseño de un plan para la protección de la especie

PALABRAS CLAVE: *Mammillaria*, Cactaceae, conservación, endemismo, extinción, Durango

ABSTRACT

We analyzed some aspects of the ecology, distribution, and conservation status of *Mammillaria theresae* Cutak (Cactaceae), a narrow endemic to the Sierra de Coneto in central Durango, Mexico. Because its isolation, this sierra has ecological and phytogeographical importance. It is located at the east of the Sierra Madre Occidental and on the western boundaries of the Chihuahuan Desert, and it is the only known locality for *M. theresae* and for a genus recently described (*Megacorax*, Onagraceae). *Mammillaria theresae* is a highly appreciated species which is locally known as peyote and peyotillo. Its population is being severely affected mainly due to the construction of a road. We evaluated the present situation of the species as well as the environmental factors with which it is related. We studied the population size from seven plots sampled across its distribution area. Density, cover and frequency of *M. theresae* and its associated species were measured, and 126 individual plants were monitored to record its fenology and dispersal mechanisms. The species grows over 1.7 ha distributed over approximately 2.5 square km along an elevational range between 2180 and 2320 m a.s.l. Because its restricted distribution, size of the population, and increasing destruction and fragmentation of its habitat, it is considered as an endangered species. This information can be used to design a plan to protect the species from further decline.

KEY WORDS: *Mammillaria*, Cactaceae, conservation, endemism, extinction, Durango, Mexico.

Las cactáceas representan un recurso único por su importancia ecológica y económica. Son apreciadas como plantas decorativas, por sus formas raras y caprichosas y por sus flores vistosas y exóticas, lo que las hace codiciadas por aficionados y coleccionistas (Sánchez-Mejorada 1979, 1982, 1982a; Becerra 2000; Benítez y Dávila 2002). Además de su importancia como ornamentales, también se utilizan como alimento, como medicinales y como materia prima en la industria rural (Rzedowski y Rzedowski 1985). De México se conocen alrededor de 822 especies, de las cuales más de 350 pertenecen al género *Mammillaria*, la mayoría endémicas del país. Algunas cactáceas están entre las plantas más amenazadas del reino vegetal, principalmente porque durante varias décadas han sido objeto de un intenso saqueo de plantas y semillas con el fin de satisfacer el mercado internacional (Benítez y Dávila 2002), y muchas están sujetas a presiones de colecta y a la destrucción de su hábitat. Regularmente tienen tasas de crecimiento muy bajas y ciclos de vida muy largos, y su reproducción es muy lenta sobre todo después de un evento de perturbación (Hernández y Godínez 1994; Arias 1998). En la Norma Oficial Mexicana (NOM-059-ECOL-2001) se reportan 285 especies de cactáceas en alguna categoría de riesgo.

Mammillaria theresae Cutak (Cactaceae) es una especie de distribución restringida a una pequeña área en la Sierra de Coneto, en el estado de Durango (Glass y Foster 1985; Bravo 1991; González et al. 1997). Forma parte de la serie *Longiflorae* (Hunt 1981, 1987), particularmente buscada por la belleza de sus flores, y es altamente apreciada por coleccionistas, particularmente europeos, por su originalidad y rareza (Fig. 1 y 2). La especie aparece por lo menos en 135 sitios de Internet, es cultivada en jardines botánicos de todo el mundo y aparece en catálogos de muchas compañías que la propagan artificialmente para venta. Hasta hace 15 años, era tanta su demanda que la población rural del área la conoce con los nombres de "peyotillo" y "peyote" al considerar erróneamente que su demanda se debía a que la planta posee propiedades alucinógenas.

Está incluida en la Norma Oficial Mexicana como especie amenazada; Vovides (1981) la cita entre las especies en peligro, y en el libro rojo de datos de la IUCN (www.redlist.org) está considerada en la categoría de especies vulnerables. Actualmente su población está siendo afectada por la ampliación del camino entre Coneto y Nuevo Ideal, que será un tramo de la carretera entre Torreón, Coahuila y Culiacán, Sinaloa. El disturbio ocasionado por la ampliación del camino y las actividades de extracción está afectando en forma severa tanto a las poblaciones de *M. theresae* como de otras especies.

El objetivo de este trabajo es contribuir al conocimiento de *M. theresae*, especialmente en lo que se refiere al tamaño y densidad de su población, su distribución, la especificidad de su hábitat y el estado actual en que se encuentra la población.

METODOLOGÍA

Tomando como base la localidad tipo de *M. theresae*, se efectuaron recorridos y observaciones a lo largo de la sierra de Coneto, apoyados en mapas de Instituto Nacional de Estadística, Geografía e Informática (INEGI). Se llevó a cabo una búsqueda intensiva en diferentes épocas del año, particularmente en áreas ecológicamente afines a la zona de donde se tenía reportada la especie.

En la única localidad donde se encontró la especie se detectaron siete poblaciones, cada una de las cuales se recorrió para determinar su superficie. En cada población se trazaron tres líneas Canfield de 20 m (Canfield 1941; citado en Mueller-Dombois y Ellenberg 1974) para cuantificar la cobertura y la frecuencia de *M. theresae* y su flora acompañante, y a lo largo de la línea media en cada lugar se colocó un bastidor de 1 m^2 a través de 10 m para determinar su densidad. Adicionalmente, en cada población se establecieron puntos fijos de muestreo de un metro cuadrado para monitorear la fenología, variación en tamaño y establecimiento de plántulas de esta especie, estudiándose un total de 126 individuos. Se llevaron a cabo colectas botánicas de la flora acompañante; el material se procesó, identificó y depositó en el Herbario CIIDIR y sus duplicados serán posteriormente distribuidos a otros herbarios. Para determinar el estado de conservación de *M. theresae* se consideraron los criterios especificados en la Norma Oficial.

Descripción del área de estudio

La Sierra de Coneto se localiza en los municipios de Nuevo Ideal y Coneto de Comonfort, en el centro del estado de Durango. Es una serranía aislada, ubicada al oriente de la Sierra Madre Occidental y en el límite occidental del Desierto Chihuahuense, entre los 24° 54' y 24° 59' N y los 104° 45' y 104° 49' W; su altitud varía entre los 2100 y los 2700 m s.n.m. (Fig. 3 y 4). El clima del área es templado semiseco (BS_1kw) de acuerdo al sistema de Koeppen, modificado por E. García (1973). La vegetación dominante es un matorral esclerófilo de *Quercus depressipes* y *Arctostaphylos pungens* con *Pinus cembroides*, *Quercus* y *Yucca*. En el estrato herbáceo destacan *Selaginella schaffneri*, *S. rupincola*, *S. pilifera*, *Sedum pringlei* y diversas gramíneas y compuestas. Este tipo de ecosistemas contribuyen a la génesis y al mantenimiento de endemismos y por lo tanto a la riqueza de la flora (Rzedowski 1978). De la zona se conoce también *Megacorax gracielanus*, género y especie descubiertos durante el desarrollo de este proyecto y recientemente descritos (González et al. 2002).

RESULTADOS Y DISCUSIÓN

Distribución y abundancia

Mammillaria theresae tiene una distribución muy restringida. Se localizó únicamente en la zona conocida como Puerto de Coneto y sus alrededores, entre los 2180 y los 2320 m, en una superficie de 1.7 ha distribuidas sobre un área de 2.5

km^2. Se distribuye en siete manchones (poblaciones) de tamaño y densidad muy diversos, en pendientes de 0° a 45° desde la parte media de las laderas hasta el pie de monte, donde es más abundante. Manifiesta preferencia por sitios con fuerte afloramiento rocoso y suelo muy somero o ausente, así como sobre grava; también se localiza debajo de piedras. Crece solitaria o en colonias; la densidad promedio de los individuos en la zona en donde mejor se desarrolla es de 1.2/m^2, aunque llega a alcanzar (incluyendo plántulas y juveniles) hasta 78 plantas/m^2 en el sitio de mayor densidad. En las poblaciones examinadas, *M. theresae* cubre el 0.059% de la superficie y presenta una frecuencia relativa de 1.11% (Cuadro 1).

Al desarrollarse en fisuras de la roca madre, esta especie afronta condiciones de escasa o nula humedad la mayor parte del año, quedando completamente expuesta al sol y al viento. Como resultado de la erosión que está sufriendo el suelo las plantas en ocasiones son arrastradas por las lluvias y la raíz queda al descubierto.

Flora acompañante

Las especies herbáceas que sobresalen tanto en cobertura como en frecuencia relativa son *Selaginella schaffneri* y *S. rupincola*, así como varias gramíneas (Cuadro 1). Las herbáceas con mayor frecuencia en el área pertenecen a las familias Selaginellaceae, Crassulaceae, Portulacaceae, Gramineae, Compositae y Euphorbiaceae. *Mammillaria theresae* se encuentra asociada principalmente a *Sedum pringlei*, *Selaginella schaffneri*, *S. rupincola* y *S. pilifera*, así como a gramíneas, otras herbáceas y musgos.

Los elementos leñosos dominantes en la zona son: *Pinus cembroides*, *Quercus depressipes* y *Arctostaphylos pungens*, mientras que *Pinus chihuahuana*, *Quercus eduardii*, *Q. emoryi*, *Garrya wrightii*, *Perymenium* sp., *Yucca* sp., *Nolina durangensis*, *N. juncea* y *Agave parryi* son escasos. En cañadas y sitios con mayor humedad ambiental se encuentran *Q. oblongifolia*, *Ceanothus greggii*, *Purshia mexicana* y, de manera muy aislada, *Arbutus arizonica*, *Quercus rugosa*, *Q. sideroxyla* y *Comarostaphylis polifolia*; en sitios más secos prevalecen *Quercus chihuahuensis*, *Mimosa aculeaticarpa* var. *biuncifera*, *M. dysocarpa*, *Dalea bicolor* y *Verbesina chihuahuensis*. La cobertura aérea y frecuencia de las principales especies leñosas se presenta en el Cuadro 2.

Por lo menos dos elementos se conocen como endémicos a la Sierra de Coneto: *M. theresae* y *Megacorax gracielanus*, género y especie descubiertos durante el desarrollo de este trabajo. Este descubrimiento confirma la necesidad de mayor exploración botánica, y no se descarta la posibilidad de encontrar más elementos de interés en el área.

Fenología

Durante la época de lluvias (mayo-julio) la planta aumenta de volumen, alcanzando su mayor tamaño (hasta 2.6 cm de diámetro y 4.2 cm de altura) entre junio y agosto, período en el que se registran incrementos desde 0.3 hasta

CUADRO 1. Cobertura y frecuencia de *Mammillaria theresae* y su flora acompañante, roca, suelo y grava. Datos en orden de importancia de acuerdo a la cobertura.

Componente	Longitud de intercepción (m)	Cobertura Relativa (%)	Frecuencia	Frecuencia Relativa (%)
Roca	158.86	37.824	346	20.13

Mammillaria sp.	0.02	0.005	3	0.17
Total	420.00	100.00	1719	100.00

1.5 cm del diámetro original. Durante 2002, en julio se presentó una tendencia a la reducción del volumen. En la Figura 5 se muestra el cambio en diámetros de la mayoría de los individuos muestreados (promedio), y en la Figura 6 se presenta el cambio ocurrido en el individuo de mayor diámetro y en los de menor diámetro registrados; la línea truncada de la Figura 6 indica la desaparición, debido a la ampliación del camino, del individuo más grande. El diámetro de los individuos adultos varía entre 0.5 y 2.6 cm. Cuando la planta alcanza su mayor tamaño, los tubérculos del tallo se alargan, llegando a medir 0.2 a 0.5 cm, y se separan entre sí hasta 0.4 cm, y la planta toma un color morado-verdoso. En la estación seca (enero-abril), las plantas pierden volumen, contrayéndose hasta más de un 50% de su tamaño y permaneciendo enterradas en el suelo y fisuras de las rocas hasta el nuevo ciclo de lluvias, lo que dificulta su localización. En el área se encuentran pequeñas rocas en forma redondeada de aspecto muy similar al de *M. theresae*.

CUADRO 2. Cobertura aérea y frecuencia de los principales elementos leñosos de la vegetación donde ocurre *Mammillaria theresae*.

Especies	Longitud de intercepción (m)	Cobertura Relativa (%)	Frecuencia	Frecuencia relativa (%)
Pinus cembroides	14.69	47.76	5	15.63

Total	30.76	100.00	32	100.00

Durante 2002, *M. theresae* presentó dos períodos de floración, uno a mediados de mayo y otro a principios de julio. Con base en estudios en vivero, Kleine & Kluger (2002) reportan que la planta florece de manera intermitente desde las primeras semanas de mayo hasta mediados de julio, presentando dos o tres períodos de floración. La flor es de color violeta pálido a intenso, de 2.5 a 4.7 cm de largo (incluyendo el tubo de 0.8 a 2.5 cm) y hasta de 4.5 cm de diámetro, con 18 a 32 pétalos; las anteras son de color amarillo intenso. En un período de floración se desarrollan una a tres, raramente cuatro, flores por individuo. La flor dura de dos a tres días, abriendo por la mañana y cerrando por la tarde. Se observaron flores ramoneadas y separadas de la planta. El fruto es rojo, diminuto, de aproximadamente 2 mm de ancho. Las semillas permanecen retenidas en la planta por varios meses, protegidas entre los lóbulos del tallo y particularmente en la base de éste, en un engrosamiento formado por el tallo que se compacta en la época seca con la parte superior de la raíz.

Dispersión

La dispersión se lleva a cabo principalmente por arrastre, ya que el fruto y las semillas son movidos por el agua o el viento. Las semillas se establecen en las fisuras de las rocas o sobre el suelo somero. Adicionalmente, las plantas muertas o desenterradas por efecto de la erosión, son arrastradas por el agua o el viento y dispersan las semillas que aún permanecían adheridas entre los lóbulos del tallo y en el engrosamiento en la base de éste, dando origen a nuevas colonias. Las plántulas aparecen en el mes de agosto, tanto aisladas como alrededor de la planta madre. No se observaron indicios de dispersión por animales, aunque cabe la posibilidad de que ocurra.

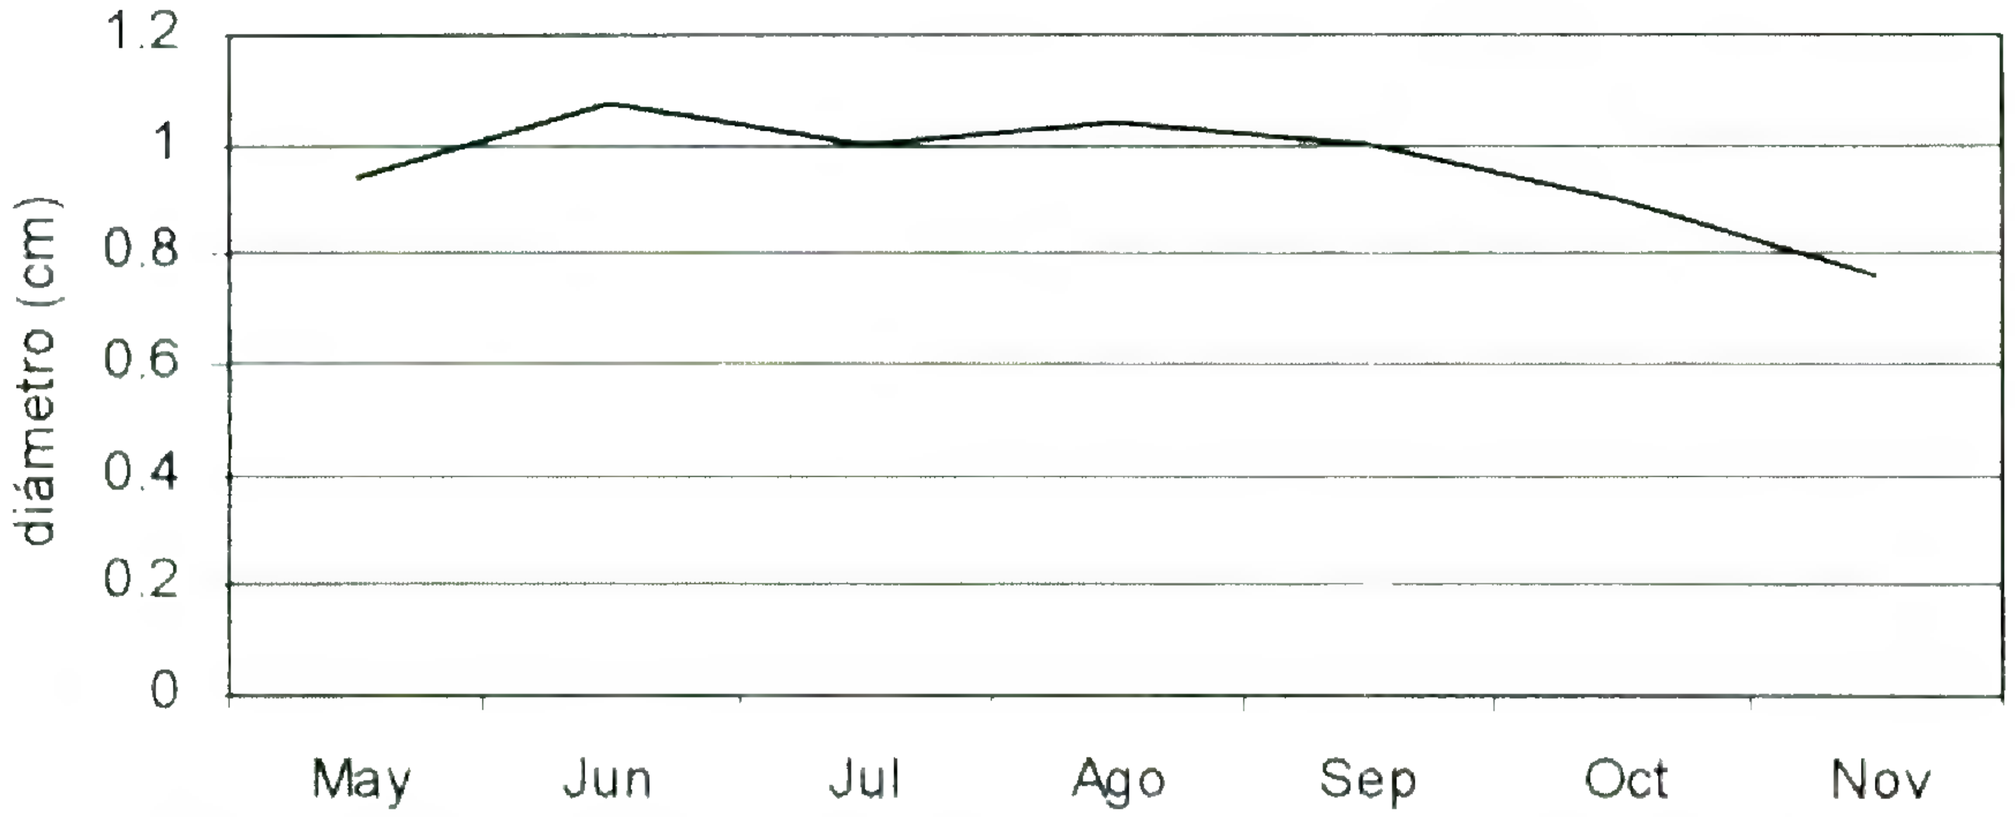

FIG. 5. Variación promedio en el diámetro de *Mammillaria theresae* durante la estación de crecimiento.

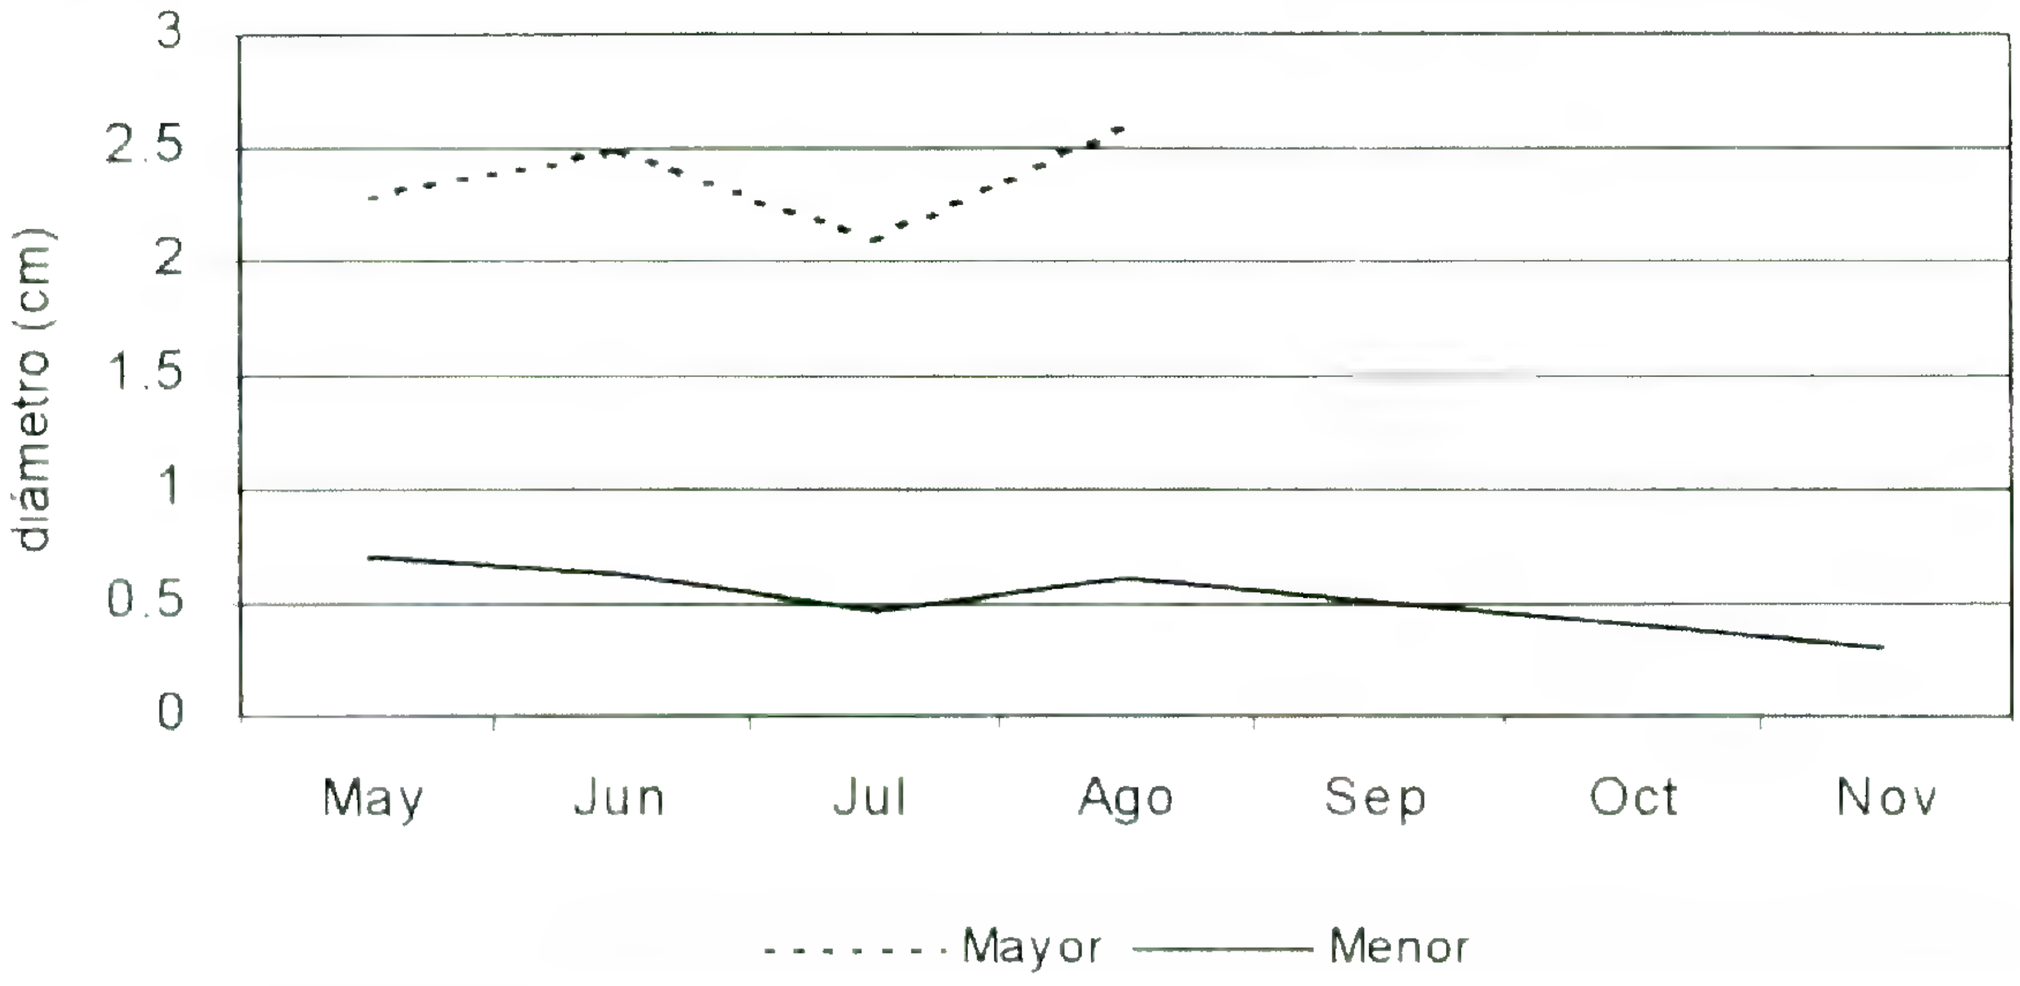

FIG. 6. Variación en el diámetro del mayor individuo de *Mammillaria theresae* registrado, y de los individuos más pequeños, durante la estación de crecimiento.

Estado de conservación

Mammillaria theresae está incluida en la Norma Oficial Mexicana (NOM-059-ECOL-2001) como especie amenazada. Hernández y Godínez (1994) y Hunt (1987), la reportan como especie amenazada, conocida únicamente de la localidad tipo, mientras que Vovides (1981), la cita como especie en peligro de extinción. Los criterios para definir "rareza" en grupos taxonómicos particulares son variables (Ceballos 2001). Se consideran especies raras aquellas que tienen distribuciones restringidas, poblaciones poco abundantes o combinaciones de ambos factores. Las especies de distribución restringida son más vulnerables a

la extinción como resultado de actividades antropogénicas que destruyen o modifican el ambiente, caso en el que se encuentra *M. theresae*. La Unión Mundial para la Naturaleza (IUCN) considera especies raras a las que tienen áreas de distribución menores de 50 000 km^2 y clasifican a *M. theresae* en la categoría de especies vulnerables. La especie no se incluye en el Apéndice I de la CITES.

Se han realizado estudios para conservar especies de cactáceas que se encuentran en alguna categoría de riesgo. Hernández y Sánchez (2000), reportan 384 especies que se encuentran en 19 colecciones de jardines botánicos en la República Mexicana, en los que se llevan a cabo acciones para conservar y reproducir especies en riesgo. No se tienen reportes de que *M. theresae* se encuentre jardines botánicos de México, a excepción probablemente del jardín botánico del Grupo Cante, en Guanajuato. La especie se ha reproducido con éxito en Europa en diversos jardines botánicos y en viveros para venta. Aunque en el Instituto Tecnológico Agropecuario No 1 de Durango se están reproduciendo las semillas con éxito, no existe un programa de dispersión de la especie en México.

Aplicando los criterios del Libro Rojo de Datos (IUCN 1980), *M. theresae* califica en la categoría de en peligro de extinción. El mismo resultado se obtiene al aplicar el método de evaluación del riesgo de extinción de especies que marca el Anexo Normativo I de la NOM-059-ECOL-2001. Por su distribución muy restringida (menos de 2 km^2), su población pequeña y el disturbio y la fragmentación de su hábitat debido a la ampliación del camino, *M. theresae* es evidentemente una especie en peligro. Por tanto, se requieren acciones inmediatas de protección que eviten su desaparición.

CONCLUSIONES

Mammillaria theresae presenta una distribución muy restringida, y hasta ahora se conoce únicamente del área conocida como Puerto de Coneto y sus alrededores. La búsqueda de *M. theresae* ha permitido el descubrimiento de un género y especie nuevos, lo que parece indicar que el área representa una zona de interés florístico que debe ser estudiada con más detenimiento.

De los diversos reportes en que se menciona a esta especie, la mayoría coinciden en que se encuentra en la categoría de amenazada. Sin embargo, el análisis de sus condiciones actuales (área de distribución muy pequeña, crecimiento lento y alteración y fragmentación en su hábitat) señala que se encuentra en peligro de extinción. Para que el desarrollo social y económico vayan a la par con la conservación de los ecosistemas, es necesario que las nuevas obras estén avaladas por un estudio de impacto ambiental previo. En el caso de la ampliación del camino que afecta a la población de *M. theresae*, de existir un estudio de impacto ambiental, no se consideró que el área representaba la única

localidad conocida de una especie, y no se aplicaron acciones que permitan mitigar el impacto en esa población. Es urgente el establecimiento de un programa para la protección de esta especie y de su hábitat.

AGRADECIMIENTOS

Los autores agradecen a la COFAA e Instituto Politécnico Nacional por el apoyo brindado para el desarrollo de este trabajo (CGPI-20010347); a M. Pinedo y S. Acevedo el apoyo brindado en campo; a Abel García Arévalo por su participación durante muestreos previos, y Barney Lipscomb y un revisor anónimo por sugerencias que permitieron mejorar el manuscrito.

BOOK NOTICES

TAYLOR & FRANCIS

Medicinal and Aromatic Plants–Industrial Profiles

Each volume in the series discusses the history and botany of each genus, and provides an in-depth look at areas such as commercial cultivation, chemical and/or pharmacological aspects, toxicology, current and/or future products, etc.

Georgios A. Petropoulos (ed.). 2002. **Fenugreek: The Genus *Trigonella*.** (ISBN 0-415-29657-9, hbk.). **Medicinal and Aromatic Plants–Industrial Profiles. Volume 11.** Series Editor: Roland Hardman. Taylor & Francis, 11 New Fetter Lane, London EC4P 4EE, UK and 29 West 35th Street, New York, NY 10001, U.S.A. (Orders: info@tandf.co.uk, www.tandf.co.uk, 44 (0) 207 583 9855, fax 44 (0) 207-842-2298, standing orders call 44 (0)1264 343071. **US and Canada Customers:** By mail: Taylor & Francis Customer Service, 10650 Toebben Drive, Independence, KY 41051, U.S.A., Toll Free Tel: 1-800-634-7064, Toll Free Fax: 1-800-248-4724, email: cserve@routledge-ny.com). $95.00, 200 pp., numerous b/w photos drawings and tables, 4 color plates 7" × 10".

From Taylor & Francis website.—"Fenugreek is the eleventh volume in the book series Medicinal and Aromatic Plants-Industrial Profiles. It presents an in-depth review on the Genus *Trigonella* and particularly the species *T. foenum-graecum* L. (fenugreek). It is written by experts and includes chapters describing the botany, physiology, cultivation, breeding, nutrition, pest-disease and weed control. Materials, dealing with the chemical constituents of the species of *Trigonella*, their pharmacological properties and the marketing of fenugreek seed are also discussed."

Contents. **1)** Introduction. **2)** Botany; **3)** Physiology; **4)** Cultivation; **5)** Breeding; **6)** Nutrition and use of fertilizers; **7)** Pests and diseases; **8)** Weeds; **9)** Chemical constituents; **10)** Pharmacological properties; **11)** Marketing; and Index.

Type localities are those places where biological specimens were obtained that subsequently were used as the basis for the scientific name and description of any organism when it was first described as new to science. Throughout the history of classical and descriptive biology, countless numbers of organisms, or taxa, have been named and described. Along with each new taxon, usually but not always, is recorded its original source location, or type locality. These type localities are deserving of permanent record, because they are the special places to which a biologist must return if he is to obtain living material from descendents of the original populations. A biologist may need to verify the identity and description of the taxon in the area where the original population occurred, obtain material for genetic and developmental studies, and/or acquire populational and life-history information. With the expansion of taxonomic studies into the broader realms of biosystematics and population analysis that has come into prominence within the past half century, much more importance is now accorded the type localities than in earlier times. These classic sites are significant biogeographical reference points at the international, national, and state levels. They should be spared from permanent destruction, such as the flooding of a river valley by construction of a dam on a stream or river, the building of a housing or industrial complex, the construction of a highway, or the tilling of the land for agricultural purposes. Type localities therefore may serve as criteria for evaluating areas or sites as potential nature sanctuaries, as discussed by Stuckey (1994).

Information on the type localities of plants first described from the United States is inadequately documented as a subject by itself. Although the information is recorded and scattered throughout the descriptive historical and botanical literature, it has not been brought together into accessible and usable data banks. Taxonomic monographs regularly include information on the type localities for names applied to the taxa discussed in those papers, but they deal only with small groups of species, and the organization is taxonomic rather than according to the geographic origin of the specimens. A project to record

SIDA 20(4): 1677–1692. 2003

type localities for species within a genus was presented in a catalogue of type specimens for names in the large genus *Carex* (Cyperaceae) (Shetler et al. 1973). It included an index to the states, provinces, and countries from which the specimens were obtained. Lists of the type specimens deposited therein have been compiled for many herbaria, but these references list specimens according to the repositories rather than according to their geographic origin. "Botanical gazetteers" have been compiled for a few states, but do not deal specifically with type localities. At the state level, we are aware of published lists of type localities for only four states, viz. Illinois (Jones 1952), Iowa (Lammers 1985), New Mexico (Standley 1910), and West Virginia (Core 1936). A few smaller lists cover either a region or a specific county in the United States. Below are listed over 60 type localities for Ohio, from which a total of 197 vascular plants were first described from the state. Stuckey and Wentz (1974) have previously catalogued the type specimens from these localities that were deposited in the herbarium of The Ohio State University.

That the precise location of the original sources of many of these new taxa described from Ohio is not given is not surprising. Many of the taxa were named in the nineteenth century, when precision as to location was of little concern, since no *International Code of Botanical Nomenclature* existed and little emphasis was placed on the source location of new biological entities. In those days it was considered sufficient to record the location of a newly described plant from such broadly defined areas as the State of Ohio, the shore of Lake Erie, the Miami River valley, or the Ohio River. The last locality, of course, means from along the banks of the Ohio River or from its vicinity. The most notable example of this situation is the 112 or more taxa described between 1808 and 1840 from Ohio by Constantine Samuel Rafinesque, who listed the source localities as "Ohio," "Lake Erie," or "Ohio River." Rafinesque's 17 vascular plants named from the shore of Lake Erie[1] and nine noted as being from the Ohio River are included in the list below, although some of Rafinesque's plants may have been obtained on the Kentucky side of the river. With the exception of one name in current usage and two upon which currently used names are based, the many taxa described by Rafinesque merely as from "Ohio" are not listed here, but they can be determined from *Index Rafinesquianum* (Merrill 1949). André Michaux's taxa described from the Ohio River are also listed, but the exact locations along the river where these plants were obtained are not known. Michaux is known to have conducted some botanical exploration near the Ohio River in the vicinity

[1]Some or perhaps all of the plants Rafinesque described from the shore of Lake Erie may have been observed at Sandusky, Erie County, where he waited three days in late May 1826 for a steamboat from Detroit that took him to Buffalo. However, during the route to Buffalo he did stop briefly at such places as Cleveland and Fairport (Rafinesque 1826, pp. 6–7; 1836a, pp. 80–81). He also noted later that the shore of Lake Erie near Sandusky represented a locality of "great botanical interest" that afforded him new species of plants (Rafinesque 1836b, pp. 28–29).

of Louisville, Kentucky, and in what is now southern Illinois, as well as near the present site of Portsmouth, Ohio. Some specimens recorded by Michaux as having been obtained from the "Ohio River" or its banks are, therefore, likely from localities outside present-day Ohio.

In other situations only the nearest town was mentioned, with no specific sites or habitats given for the plant. Some sites are sufficiently well described so that their locations can be determined today. Among the best-known type localities in Ohio from which vascular plants have been described are Beaver Pond in Adams County, Cedar Bog (Cedar Swamp) in Champaign County, Cedar Point and other locations near Sandusky in Erie County, the limestone cliffs along the Scioto River north of Columbus and other sites in Franklin County, Hoffman's Prairie (Wright Brothers Prairie) east of Dayton in Greene County, Rocky Fork Creek in Highland County, Ofer Hollow in Jackson County, and Cranberry Island in Buckeye Lake in Licking County. Significant type localities that have disappeared through agricultural or industrial development include the Oxford Prairie in Erie County, the Darby Plains in Madison County, and Van Cleve's Prairie near Dayton in Montgomery County.

The general locations of the type localities listed below are shown on a map of Ohio (Fig. 1), and two additional maps show portions of the state where many type localities are concentrated in small areas (Figs. 2, 3). The localities are concentrated mostly in the Miami valley in southwestern Ohio, in Franklin and adjacent counties in central Ohio, and near Lake Erie in northern Ohio. These locations reflect the pioneer botanical exploration in Ohio, first in the Miami River valley in the early 1800s, in central Ohio mostly in the mid 1800s, and in northern Ohio primarily about 1900 and later. The more unusual habitat types represented are fens, wet prairies, and limestone cliffs. These habitats are not well represented in the states to the east of Ohio where most of the descriptive botany had been written before the early 1800s. It is understandable, therefore, that plants characteristic of these habitats that had not previously been named and described were first described from places in Ohio.

Unlike the other state lists mentioned above, which were arranged alphabetically by taxon, this list for Ohio is organized by locality, beginning with the largest unit, Ohio, followed by sections of the state including the shore of Lake Erie, the Miami River valley, and the Ohio River valley, and then alphabetically by county. Those taxa with more specific locality data are listed under each county. If two or more localities in Ohio were cited when a taxon was first described, as for example with *Valeriana ciliata* Torr. & A.Gray, all such localities are listed. All of the names based on specimens from the same type locality are listed under that locality, in alphabetical order. An index to names of taxa, by genus only, begins on page 1691.

Double asterisks denote plant names that are currently accepted as the correct names for the respective taxa. Single asterisks denote names that are no

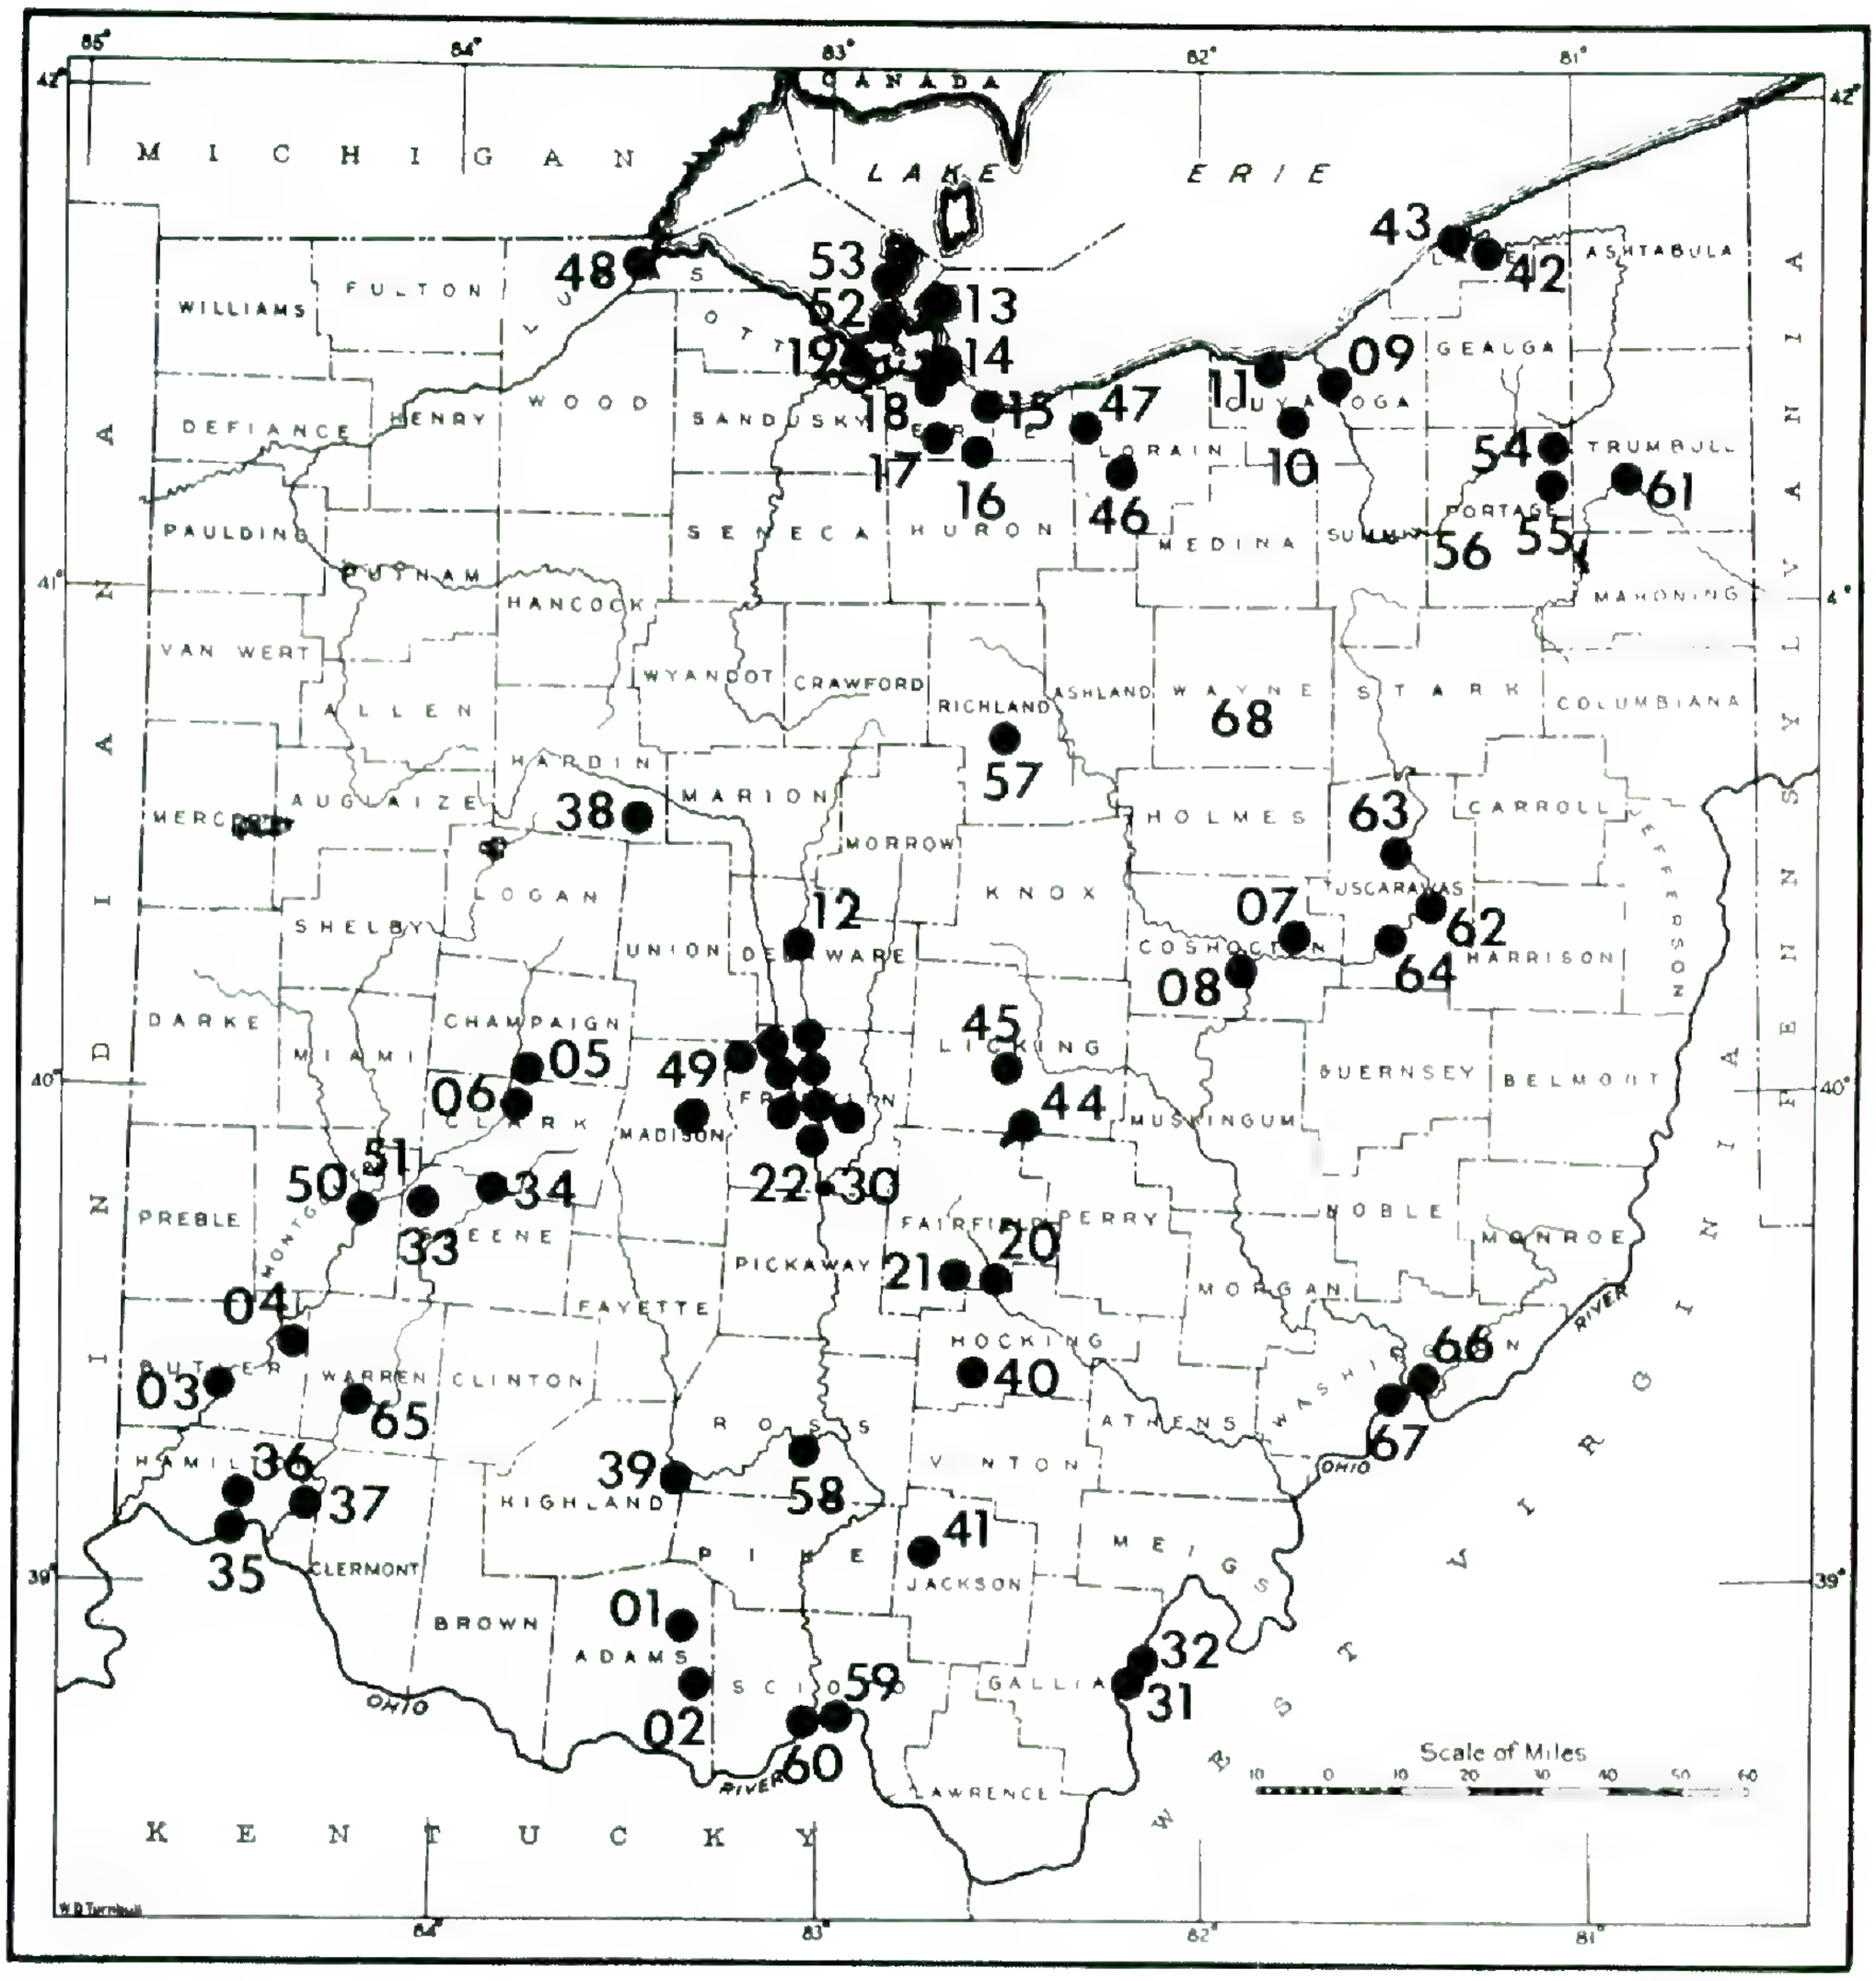

FIG. 1. Map of Ohio showing by numbered dot the type localities of vascular plants first described from that state in the United States of America. Those numbers without dots indicate that the type location in that county is not known.

longer in use, or at least are not accepted in the standard references consulted in the present study, but which have been superseded by currently accepted names based directly upon them. Single asterisks are also used for the names of taxa originally described as species that are now considered to be interspecific hybrids. In these cases, the present-day name generally includes the original epithet, meaning the adjectival component of the name in a nomenclatural combination that was published later. The type localities remain the same. When the name based on a specimen or specimens obtained in Ohio is no longer in use for a taxon, the currently accepted name is given in brackets when possible. Currently accepted names and taxonomic synonymy have been deter-

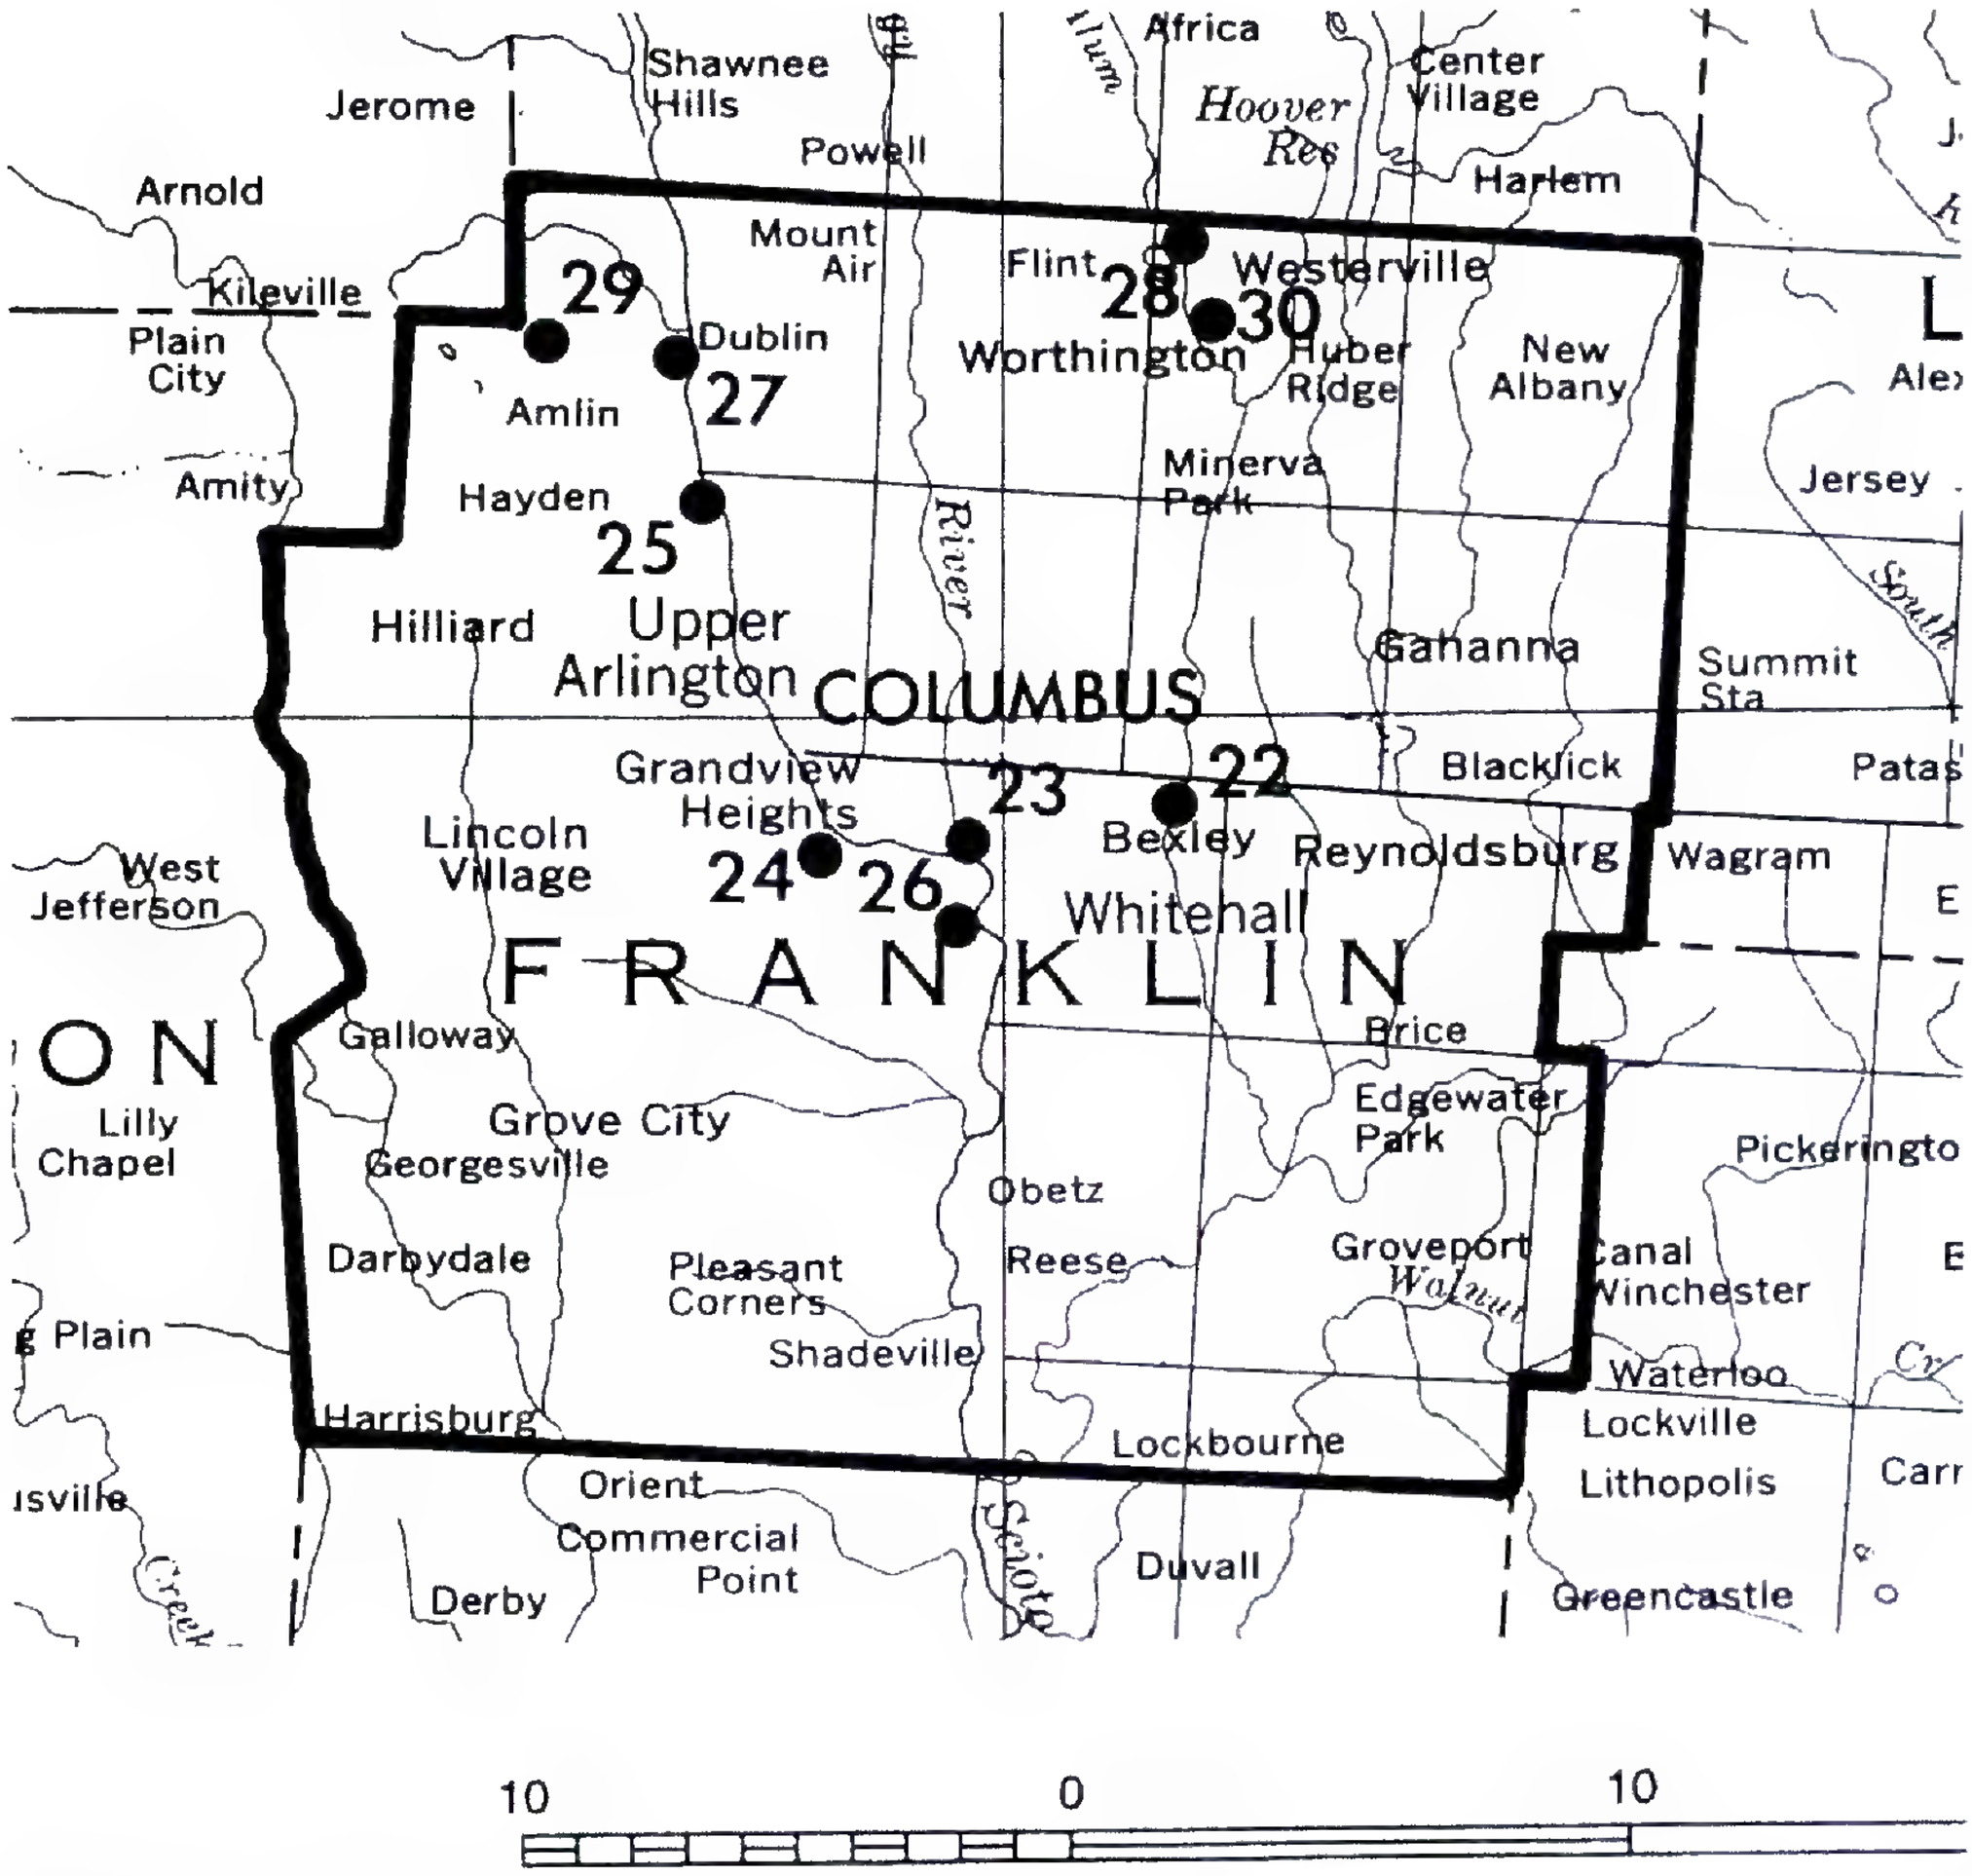

FIG. 2. Map of Franklin County, Ohio, showing by numbered dot the type localities of vascular plants first described from that county in Ohio.

mined primarily from Kartesz (1994), Kartesz and Meacham (1999), and those volumes of the *Flora of North America North of Mexico* that had been published at the time of this writing. For some old names not listed even in synonymy in these works, the modern equivalents have been determined from older floras, such as those by Britton and Brown (1913), Fernald (1950), and Gleason (1952), and from monographs, notably those by Boivin (1944) on *Thalictrum*, Davis et al. (1967–1970) on *Rubus*, Fernald (1905) on *Eriophorum*, Heiser et al. (1969) on *Helianthus*, Mackenzie (1931–1935) on *Carex*, and Palmer (1956, 1961) on *Crataegus*. When no current status or taxonomic equivalent is given for a name published at the rank of variety, it may be inferred that varieties are now gener-

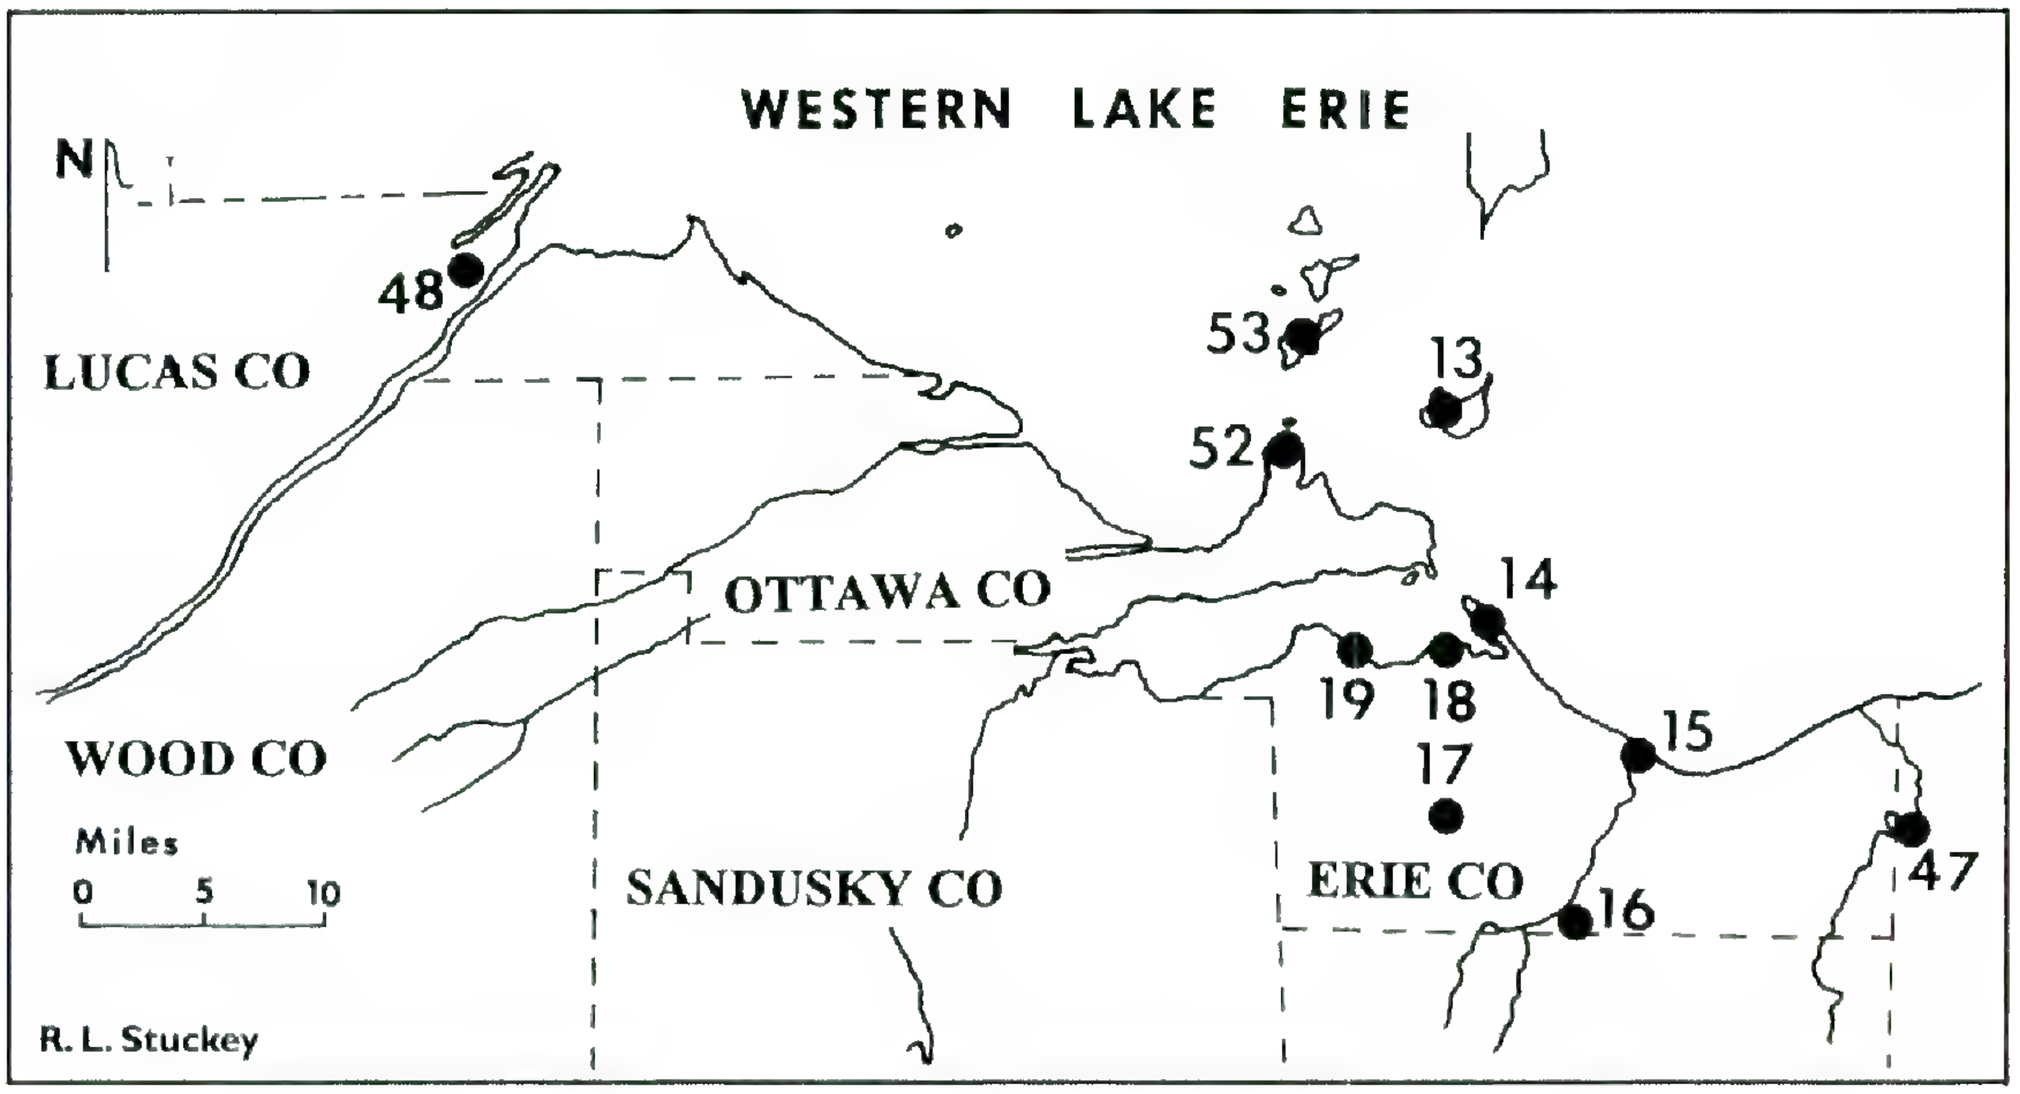

FIG. 3. Map of the Ohio counties along the shoreline of Western Lake Erie showing by numbered dot the type localities of vascular plants first described from this region of Ohio.

ally not recognized within that species. In these cases, when a synonym is given for the species, it should not be assumed that the minor variant described as a variety is equivalent to the entire species. Current status is not indicated for names published at the rank of form (Latin *forma*, abbreviation "f."), because names at this rank are not usually included in modern floras. In most cases, the original epithet applied to the form, transferred if necessary to the currently accepted name for the species, which is indicated here, would be correct for anyone wishing to use names for these individual variations.

In some cases it has not been possible to equate an older name with any currently accepted taxonomic equivalent. When the original description is deficient in detail and the original specimens no longer exist, it may not be certain to which currently recognized taxon an old name, based on plants occurring in Ohio, was applied, although taxonomic research continues to resolve some of these long-persistent questions. This situation is an especially frequent problem with plants named by Rafinesque. The best single source for their interpretation is Merrill's (1949) *Index Rafinesquianum*. Other publications that are especially significant with regard to plants originally described from Ohio specimens include the first author's studies of the plants named and described by Daniel Drake (Stuckey 1969) and Thomas Nuttall (Stuckey 1966, 1967), and his studies of the plants described by C.S. Kunth and E.G. von Steudel from specimens obtained in the Miami River valley by Joseph Frank (Stuckey 1974).

THE PLANTS AND THEIR TYPE LOCALITIES

OHIO

****Acalypha rhomboidea** Raf., New Fl. 1:45. 1836 [sometimes included in *Acalypha virginica* L., as var. *rhomboidea* (Raf.) Cooperr.].

Aesculus ohioensis Riddell, W.J. Med. Phys. Sci. 8:360. 1835. Reprint p. 34. 1835 [*Aesculus glabra* Willd.].

Cakile americana Nutt., Gen. N. Amer. Pl. 2:62. 1818 [*Cakile edentula* (Bigelow) Hook. subsp. *edentula*].

Carex laxiflora Lam. var. *latifolia* Boott, Ill. Carex p. 38, pl. 93. 1858 [*Carex albursina* E.Sheld.].

Carex alata Torr. var. *ferruginea* Fernald, Proc. Amer. Acad. Arts 37:477, pl. 2. 1902 [*Carex suberecta* (Olney) Britton].

****Carex comosa** Boott, Trans. Linn. Soc. London 20:117. 1846.

Carex davisii Schwein. & Torr. f. *glabrescens* Kük. in Engl., Pflanzenr. 4(20):588. 1909.

Carex foenea Willd. var. β Boott, Ill. Carex p. 118, pl. 376. 1862 [*Carex suberecta* (Olney) Britton].

Carex foenea Willd. var. *ferruginea* A.Gray, Manual, ed. 5, p. 580. 1867 [*Carex suberecta* (Olney) Britton].

Carex laxiflora Lam. var. *blanda* (Dewey) Boott subvar. *gracillima* Boott, Ill. Carex p. 38, pl. 91, fig. 2. 1858 [*Carex gracilescens* Steud.].

***Carex monile** Tuck., Enum. Meth. Caric. p. 20. 1843 [*Carex vesicaria* L. var. *monile* (Tuck.) Fernald].

***Carex tenera** Dewey var. *suberecta* Olney, Carices Bor.-Amer. 3:1871 [*Carex suberecta* (Olney) Britton].

Crataegus ridgwayi Sarg., J. Arnold Arbor. 6:2. 1925 [*Crataegus mollis* (Torr. & A.Gray) Scheele].

***Cyanotris scilloides** Raf., Amer. Monthly Mag. & Crit. Rev. 3:356. 1818 [*Camassia sciloides* (Raf.) Cory].

****Eleocharis erythropoda** Steud., Syn. Pl. Glumac. 2:76. 1854 [long known as *Eleocharis calva* Torr., an invalid name].

Eriophorum gracile W.D.J.Koch ex Roth [var.] β *paucinervium* Engelm., Amer. J. Sci. Arts 46:103. 1844 [*Eriophorum tenellum* Nutt.].

***Eriophorum latifolium** Hoppe [var.] β *viridicarinatum* Engelm., Amer. J. Sci. Arts 46:103. 1844, "*viridi-carinatum*" [*Eriophorum viridicarinatum* (Engelm.) Fernald].

****Euphorbia commutata** Engelm. ex A.Gray, Manual, ed. 2., p. 389. 1856.

Fimbristylis frankii Steud., Syn. Pl. Glumac. 2:111. 1855 [*Fimbristylis autumnalis* (L.) Roem. & Schult.].

***Hedysarum pauciflorum** Nutt., Gen. N. Amer. Pl. 2:109. 1818 [*Desmodium pauciflorum* (Nutt.) DC.].

****Helianthus microcephalus** Torr. & A.Gray, Fl. N. Amer. 2:329. 1842.

Hydrophyllum hispidum Riddell, W.J. Med. Phys. Sci. 8:516. 1835. Reprint p. 84. 1835 [*Hydrophyllum macrophyllum* Nutt.].

****Juncus brachycarpus** Engelm., Trans. Acad. Sci. St. Louis 2:467. 1868.

***Juncus canadensis** J.Gay var. *brachycephalus* Engelm., Trans. Acad. Sci. St. Louis 2:474. 1868 [*Juncus brachycephalus* (Engelm.) Buchenau].

Lysimachia revoluta Nutt., Gen. N. Amer. Pl. 1:122. 1818 [*Lysimachia quadriflora* Sims].

****Poa sylvestris** A.Gray, Manual, ed. 1, p. 596. 1848.

Scutellaria ambigua Nutt., Gen. N. Amer. Pl. 2:37. 1818 [*Scutellaria nervosa* Pursh].

Scutellaria versicolor Nutt., Gen. N. Amer. Pl. 2:38. 1818 [*Scutellaria ovata* Hill subsp. *ovata*].

****Stachys cordata** Riddell, W.J. Med. Phys. Sci. 9:579. 1836. Reprint p. 15. 1836 [often called *Stachys nuttallii* Shuttlew. ex Benth. in recent literature, but no valid reason exists to reject the name *S. cordata* Riddell].

***Tetraneuris herbacea** Greene, Pittonia 3:368. 1898 [now usually treated as *Hymenoxys herbacea* (Greene) Cusick, but sometimes retained in *Tetraneuris*].

****Tradescantia ohioensis** Raf., Précis Découv. Somiol. p. 45. 1814; see also New Fl. N. Amer. 2:84. 1836 [1837].

Vernonia altissima Nutt., Gen. N. Amer. Pl. 2:134. 1818 [*Vernonia gigantea* (Walter) Trel. subsp. *gigantea*].

LAKE ERIE, SHORE OF (Probably at Sandusky, Erie County)

Aesculus muricata Raf., Alsogr. Amer. p. 68. 1838 [*Aesculus glabra* Willd.].

Asclepias dasypus Raf., Atlantic J. 1:152. 1832 [*Asclepias purpurascens* L.].

Asclepias rotundifolia Raf., Atlantic J. 1:152. 1832, not Mill. 1768 [*Asclepias amplexicaulis* J.E.Sm.].

Caprifolium dentatum Raf., Atlantic J. 1:151. 1832 [*Lonicera dioica* L.].

Cornus punctata Raf., Alsogr. Amer. p. 62. 1838 [*Cornus alternifolia* L.].

Cornus suffruticosa Raf., Atlantic J. 1:151. 1832; Alsogr. Amer. p. 61. 1838.

Fragaria elatior Raf., Atlantic J. 1:152. 1832, not Ehrh. 1792 nor Wight & Arn. 1834.

Fragaria serotina Raf., Atlantic J. 1:152. 1832.

Lathyrus incurvus Raf., Atlantic J. 1:151. 1832, not Roth 1787 nor Willd. 1802 nor Rchb. 1832.

Lobelia falcata Raf., New Fl. 2:18. 1836 [1837] [*Lobelia kalmii* L.].

Lonicera eriensis Raf., New Fl. 3:18-19. 1836 [1838] [?*Lonicera hirsuta* Eaton].

Lysimachia sessilifolia Raf., Atlantic J. 1:151. 1832 [*Lysimachia quadriflora* Sims].

Mentha traxigona Raf., Autik. Bot. p. 114. 1840.

Samolus petiolatus Raf., Herb. Raf. p. 41. 1833 [*Samolus valerandi* L. subsp. *paviflorus* (Raf.) Hultén].

Trillium brevipetalum Raf., Med. Fl. 2:100. 1830; Autik. Bot. p. 134. 1840 [*Trillium flexipes* Raf.].

Trillium rotundifolium Raf., Med. Fl. 2:97. 1830 [*Trillium erectum* L.].

Viola eriocarpa Raf., Atlantic J. 1:152. 1832 [nomenclaturally distinct from *Viola eriocarpa* Schwein. (1822), although probably taxonomically equivalent].

MIAMI VALLEY; MIAMI COUNTRY

**Ampelopsis quinquefolia* Michx. var. *vitacea* Knerr, Bot. Gaz. 18:70. 1893 [*Parthenocissus vitacea* (Knerr) Hitchc.].

Convolvulus micranthus Riddell, W.J. Med. Phys. Sci. 8:502. 1835. Reprint p. 70. 1835, not Roem. & Schult. 1819 nor Willd. ex Spreng. 1824 [*Ipomoea lacunosa* L.].

Carex flaccidula Steud., Syn. Pl. Glumac. 2:199. 1855 [*Carex rosea* Schkuhr ex Willd.].

***Carex gracilescens* Steud., Syn. Pl. Glumac. 2:226. 1855. 1849.

Carex steudelii Kunth, Enum. Pl. 2:480. 1837 [*Carex jamesii* Schwein.].

Eragrostis cognata Steud., Syn. Pl. Glumac. 1:273. 1854 [*Eragrostis pectinacea* (Michx.) Nees ex Steud.].

***Eragrostis frankii* C.A.Mey. ex Steud., Syn. Pl. Glumac. 1:273. 1854.

Eragrostis unionis Steud., Syn. Pl. Glumac. 1:273. 1854 [*Eragrostis pectinacea* (Michx.) Nees ex Steud.].

Valerianella triquetra Hochst. & Steud. ex Shuttlew., Flora 20:211. 1837 [*Valerianella chenopodiifolia* (Pursh) DC.].

OHIO RIVER

Asplenium angustifolium Michx., Fl. Bor.-Amer. 2:265. 1803 [*Diplazium pycnocarpon* (Spreng.) M.Broun].

Discovium gracile Raf., J. Phys. Chim. Hist. Nat. Arts 89:96. 1819 [?*Lesquerella globosa* (Desv.) S.Watson].

Eupatorium longipes Raf., Atlantic J. 1:17. 1832.

Eupatorium pectinatum Raf., Atlantic J. 1:17. 1832, not Wall. 1831 nor Small 1903.

Euphorbia thymifolia Michx., Fl. Bor.-Amer. 2:212. 1803, not L. 1753 [*Chamaesyce maculata* (L.) Small; sometimes retained in *Euphorbia*, as *E. maculata* L.].

Hibiscus hastatus Michx., Fl. Bor.-Amer. 2:45. 1803, not L.f. 1781 nor Cav. 1787 [*Hibiscus laevis* All.].

Ilysanthes riparia Raf., Ann. Nat. 1:13 1820 [*Lindernia dubia* (L.) Pennell var. *dubia*].

Lithospermum angustifolium Michx., Fl. Bor.-Amer. 1:130. 1803, not Forssk. 1775 nor Sessé & Moç. 1893 [*Lithospermum incisum* Lehm.].

Planera gmelinii Michx., Fl. Bor.-Amer. 2:248. 1803, "*gmelini*" [*Planera aquatica* (Walter) J.F.Gmel.].

Podalyria coerulea Michx., Fl. Bor.-Amer. 1:264. 1803 [*Baptisia australis* (L.) R.Br. ex W.T.Aiton var. *australis*].

***Polygonum amphibium* L. [var.] β *emersum* Michx., Fl. Bor.-Amer. 1:240. 1803.

Potamogeton natans L. [var.] β Michx., Fl. Bor.-Amer. 1:101. 1803 [*Potamogeton epihydrus* Raf.].

***Potentilla paradoxa* Nutt. in Torr. & A.Gray, Fl. N. Amer. 1:437. 1840, not Schur ex Nyman 1878.

Scutellaria radicata Raf., Atlantic J. 1:16. 1832.

***Spermacoce glabra* Michx., Fl. Bor. Amer. 1:82. 1803, not Roxb. 1820 nor Sessé & Moç. 1888.

Tilia fulva Raf., Alsogr. Amer. 45. 1838 [*Tilia americana* L.].

Vitis odoratissima Donn var. *atropurpurea* Raf., Med. Fl. 2:132. 1830.

****Vitis riparia** Michx., Fl. Bor.-Amer. 2:231. 1803.

ADAMS COUNTY

01. Beaver Pond: ****Asplenium ×inexpectatus** E.L.Braun ex C.V.Morton, Amer. Fern J. 46:152. "1956" [1957]. [= *Asplenium cryptolepis* Fernald × *A. rhizophyllum* (L.) Link; earlier binomial ×*Asplenosorus inexpectatus* E.L.Braun ex Friesner, Butler Univ. Bot. Stud. 4:154. 1940 was not validly published].

02. Prairie, north part of Jefferson Township, southeast of Scrub Ridge, 2 1/2 miles north of Ohio Route 348: ****Silphium terebinthinaceum** Jacq. var. *lucy-brauniae* Steyerm., Rhodora 53:133–135. 1951.

BUTLER COUNTY

03. Old prairie near Hamilton: *Amaranthus altissimus* Riddell, W.J. Med. Phys. Sci. 8:367. 1835. Reprint p. 41. 1835 [*Amaranthus tuberculatus* (Moq.) J.D.Sauer].

04. Small prairie half a mile south of Middletown: *Euphorbia herronii* Riddell, W.J. Med. Phys. Sci. 8:58. 1835. Reprint p. 32. 1835 [*Euphorbia dentata* Michx.].

CHAMPAIGN COUNTY

05. Cedar Swamp [now Cedar Bog], Urbana: ***Valeriana ciliata** Torr. & A.Gray, Fl. N. Amer. 2:49. 1841 [*Valeriana edulis* Nutt. ex Torr. & A.Gray var. *ciliata* (Torr. & A.Gray) Cronquist].

CLARK COUNTY

06. Near Springfield: ***Valeriana ciliata** Torr. & A.Gray, Fl. N. Amer. 2:49. 1841 [*Valeriana edulis* Nutt. ex Torr. & A.Gray var. *ciliata* Cronquist].

COSHOCTON COUNTY

07. North Appalachian Experimental Watershed, near Fresno, Chili, and Canal Lewisville:

Aralia spinosa L. f. *subinermis* Moldenke, Castanea 9:54. 1944.

Daucus carota L. f. *fischeri* Moldenke, Castanea 9:55. 1944.

Daucus carota L. f. *goodmanii* Moldenke, Castanea 9:55. 1944, "*goodmani*."

Lobelia inflata L. f. *albiflora* Moldenke, Castanea 9:65. 1944.

Lycopodium flabelliforme (Fernald) Blanch. f. *clutei* Moldenke, Castanea 9:32. 1944. [*Diphasiastrum digitatum* (A.Braun) Holub].

Morus alba L. f. *nigrobacca* Moldenke, Castanea 9:51. 1944.

Plantago rugelii Decne. f. *fasciculata* Moldenke, Castanea 9:65. 1944.

Tovara virginiana (L.) Raf. f. *rubra* Moldenke, Boissiera 7:4. 1943; see also Castanea 9:40. 1944 [*Polygonum virginiana* L.]. Although one might infer otherwise from Moldenke's paper in Castanea, this and the following two names were validly published in Boissiera.

Tracaulon sagittatum (L.) Small f. *subalbidum* Moldenke, Castanea 9:41. 1944 [*Polygonum sagittatum* L.].

Trifolium pratense L. f. *lilacinum* Moldenke, Boissiera 7:4–5. 1943; see also Castanea 9:49. 1944.

Vernonia altissima Nutt. f. *alba* Moldenke, Boissiera 7:5. 1943; see also Castanea 9:64. 1944 [*Vernonia gigantea* (Walter) Trel. subsp. *gigantea*].

08. Roscoe: *Stachys glabra* Riddell, W.J. Med. Phys. Sci. 9:580. 1836. Reprint p. 16. 1836 [*Stachys tenuifolia* Willd.].

CUYAHOGA COUNTY

09. Cuyahoga: *Hieracium watsonianum* Gand., Bull. Soc. Bot. France 65:49. 1918.

10. Parma: *Hieracium ohioense* Gand., Bull. Soc. Bot. France 65:48. 1918.

11. Rocky River, deep gorge about one-fourth mile from Lake Erie: *Cerastium arvense* L. var. *webbii* Jennings, Ohio Naturalist 9:441. 1909; see also Ohio Naturalist 10:136. 1910 [*Cerastium arvense* L. subsp. *velutinum* (Raf.) Ugbor. var. *velutinum*.]

DELAWARE COUNTY

12. Delaware: *Crataegus ellipticifolia* Sarg., J. Arnold Arbor. 3:194. 1922 [*Crataegus compacta* Sarg.].

ERIE COUNTY

13. Kelleys Island, bottom of deep northwest quarry by glacial grooves, N portion of Kelleys Island, Lake Erie: ****Juncus ×stuckeyi** M.Reinking, Brittonia 33:175. 1976 [= *Juncus alpinoarticulatus* Chaix × *J. torreyi* Coville].

14. Cedar Point: ***Helianthus luxurians** E.Watson, Pap. Michigan Acad. Sci. 9:464. 1929 [*Helianthus ×luxurians* E.Watson; pro sp.; = *H. giganteus* L. × *H. grosseserratus* M.Martens].

15. Huron River at mouth: *Phalangium esculentum* Nutt., Gen. N. Amer. Pl. 1:219. 1818 [*Camassia scilloides* (Raf.) Cory].

16. Milan: *Crataegus propinqua* Ashe, J. Elisha Mitchell Sci. Soc. 20:53–54. 1904 [*Crataegus iracunda* Beadle].

17. Oxford Prairie: *Solidago moseleyi* Fernald, Rhodora 10:93. 1908 [*Euthamia gymnospermoides* Greene; often included in *Solidago*, as *S. gymnospermoides* (Greene) Fernald].

Thalictrum moseleyi Greene, Amer. Midl. Naturalist 2:294. 1912 [*Thalictrum dasycarpum* Fischer & Avé-Lall.].

18. Sandusky: *Crataegus marcida* Ashe, J. Elisha Mitchell Sci. Soc. 20:53. 1904 [*Crataegus iracunda* Beadle].

Crataegus tenera Ashe, J. Elisha Mitchell Sci. Soc. 20:52–53. 1904 [*Crataegus macrosperma* Ashe].

19. Sandusky Bay: *Vicia douglassii* Torr., Amer. J. Sci. 4:66. 1822 [?*Vicia cracca* L.].

FAIRFIELD COUNTY

20. Sugar Grove: *Crataegus polybracteata* Ashe, J. Elisha Mitchell Sci. Soc. 16:79. 1899; see also E.J. Palmer, J. Arnold Arbor. 6:57. 1925 [*Crataegus intricata* Lange].

21. Clearport; T.12N, R.19W, sec. 10, 1.5 miles east of Clearport on the south side of County Highway 69, east of the covered bridge over Clear Creek: ***Cystopteris ×wagneri* R.C. Moran, Castanea 48:224. 1983 [– *Cystopteris tennesseensis* Shaver × *C. tenuis* (Michx.) Desv.].

FRANKLIN COUNTY

22. Bexley: *Triphora trianthophora* (Sw.) Rydb. var. *schaffneri* Camp, Rhodora 42:55. 1940.

23. Columbus: ***Asclepias sullivantii* Engelm. ex A.Gray, Manual, ed. 1, 366. 1848.

Aster laxifolius Nees [var.] β *laetiflorus* Torr. & A.Gray, Fl. N. Amer. 2:138. 1841 [*Aster borealis* (Torr. & A.Gray) Prov.; sometimes segregated from *Aster* as *Symphyotrichum boreale* Torr. & A.Gray) A.Löve & D.Löve].

***Carex conjuncta* Boott, Ill. Carex 3:122, pl. 392. 1862.

**Carex sullivantii* Boott in A.Gray, Amer. J. Sci. 42:29. 1842 [*Carex ×sullivantii* Boott, pro sp.; = *Carex hirtifolia* Mack. × *C. gracillima* Schwein.].

Crataegus ohioensis Sarg., J. Arnold Arbor. 3:183. 1922 [*Crataegus arborea* Beadle].

Fedia patellaria Sull. ex A.Gray, Manual, ed. 1, 183. 1848 [*Valerianella umbilicata* (Sull.) Alph. Wood].

**Fedia umbilicata* Sull., Amer. J. Sci. 42:50. 1842 [*Valerianella umbilicata* (Sull.) Alph.Wood].

**Helianthus kellermanii* Britton, Man. Fl. N. States p. 994. 1901, "*kellermani*"; see also W.A. Kellerman, Ohio Naturalist 2:179–181. 1902 [*Helianthus ×kellermanii* Britton, pro sp.; = *Helianthus salicifolius* A.Dietr. × *H. grosseserratus* M.Martens].

**Rudbeckia sullivantii* C.L.Boynton & Beadle, Biltmore Bot. Stud. 1:15. 1901 [*Rudbeckia fulgida* Aiton var. *sullivantii* (C.L.Boynton & Beadle) Cronquist].

24. Columbus, cat-tail swamp, three miles west: **Coreopsis discoidea* Torr. & A.Gray, Fl. N. Amer. 2:339. 1842 [*Bidens discoidea* (Torr. & A.Gray) Britton].

25. Columbus, rocky limestone banks of the Scioto River: ***Arabis patens* Sull., Amer. J. Sci. 42:49. 1842, not Royle ex Hook.f. & Thomson 1861.

**Lonicera glaucescens* Rydb. var. *dasygyna* Rehder, Annual Rep. Missouri Bot. Gard. 14:181. 1903 [*Lonicera dioica* L. var. *dasygyna* (Rehder) Gleason].

Lonicera flava Sims var. β Torr. & A.Gray, Fl. N. Amer. 2:6. 1841 [*Lonicera reticulata* Raf.].

Lonicera parviflora Lam. [var.] β? [sic] *sullivantii* Alph.Wood, Class-book Bot., ed. 2, p. 298. 1847. Based on the Ohio component of *Lonicera parviflora* var. β Hook. sensu Torr. & A.Gray, Fl. N. Amer. 2:7. 1841, but nomenclaturally distinct; type locality determined from Torrey and Gray [*Lonicera reticulata* Raf.].

26. Columbus, two miles south: ***Solidago ohioensis* Riddell, W.J. Med. Phys. Sci. 8:497. 1835. Reprint p. 57. 1835 [sometimes segregated from *Solidago* as *Oligoneuron ohioense* (Riddell) G.N.Jones].

27. Dublin, calcareous ravine and steep declivity on the Scioto River: *Prenanthes proteophylla* Riddell, W.J. Med. Phys. Sci. 8:490. 1835. Reprint p. 50. 1835 [*Prenanthes alba* L.].

***Trillium nivale* Riddell, W.J. Med. Phys. Sci. 8:525. 1835. Reprint p. 93. 1835.

28. Between Flint and Glenmary: *Crataegus franklinensis* Sarg., J. Arnold Arbor. 4:100. 1923 [*Crataegus dissona* Sarg.].

29. Scott's Plains, 12 miles east from Worthington: ****Solidago riddellii* Frank in Riddell, W.J. Med. Phys. Sci. 8:497. 1835. Reprint p. 57. 1835 [sometimes segregated from *Solidago* as *Oligoneuron riddellii* (Frank) Rydb.]. Riddell probably should have written west instead of east, because of the prairie habitat in that area west of Worthington, rather than in the forest east of Worthington (R.L.S.).

30. Worthington: *Aster carneus* Nees var. *ambiguus* Torr. & A.Gray, Fl. N. Amer. 2:133. 1841 [*Aster lanceolatus* Willd. var. *interior* (Wiegand) Semple & Chmiel.; sometimes segregated from *Aster* as *Symphyotrichum lanceolatum* subsp. *lanceolatum* var. *interior* (Wiegand) G.L.Nesom].

****Aster oolentangiensis* Riddell, W.J. Med. Phys. Sci. 8: 495. 1835. Reprint p. 55. 1835 sometimes segregated from *Aster* as *Symphyotrichum oolentangiense* (Riddell) G.L.Nesom].

Prenanthes parviflora Riddell, W.J. Med. Phys. Sci. 8:490. 1835. Reprint p. 50 [*Prenanthes altissima* L.].

Stachys glabra Riddell, W.J. Med. Phys. Sci. 9: 580. 1836. Reprint p. 16. 1836 [*Stachys tenuifolia* Willd.].

GALLIA COUNTY

31. Gallipolis: *Crataegus horseyi* E.J.Palmer, Ohio J. Sci. 56:211–212. 1956 [*Crataegus intricata* Lange].

32. Gallipolis, banks of the Ohio River: ****Collinsia verna* Nutt., J. Acad. Nat. Sci. Philadelphia 1:190. 1817.

Discovium ohioense Raf., Autik. Bot. 17. 1840 [?*Lesquerella globosa* (Desv.) S.Watson].

GREENE COUNTY

33. Hoffman's Prairie, eight miles east from Dayton: *Amaranthus miamiensis* Riddell, W.J. Med. Phys. Sci. 8:367. 1835. Reprint p. 41. 1835 [*Amaranthus tuberculatus* (Moq.) J.D.Sauer].

****Solidago riddellii* Frank in Riddell, W.J. Med. Phys. Sci. 8: 497. 1835. Reprint p. 57. 1835. This locality is now referred to as the Wright Brothers Prairie or Wright Patterson Natural Area, which is located within the Wright Patterson Air Force Base east of Dayton, Ohio (Knoop, 2002).

34. Yellow Springs: *Asplenium cryptolepis* Fernald var. *ohionis* Fernald, Rhodora 30:43. 1928 [*Asplenium ruta-muraria* L., usually not recognized at the varietal level; when accepted, the correct epithet is in doubt as of this writing, but evidently would not be *ohionis*].

HAMILTON COUNTY

35. Cincinnati: *Aesculus maxima* D.Drake, Natural and Statistical View, or Picture of Cincinnati and the Miami Country ... p. 78. 1815 [1816] [*Aesculus flava* Aiton].

Enslenia albida Nutt., Gen. N. Amer. Pl. 1:164. 1818 [*Cynanchum laeve* (Michx.) Pers.].

****Erythronium albidum* Nutt., Gen. N. Amer. Pl. 1:223. 1818.

Synandra grandiflora Nutt., Gen. N. Amer. Pl. 2:29. 1818 [*Synandra hispidula* (Michx.) Baill.].

36. Three miles north of Cincinnati: **Quercus leana* Nutt., Sylva 1:13. 1849 [*Quercus ×leana* Nutt., pro sp.; = *Quercus imbricaria* Michx. × *Q. velutina* Lam.].

37. Near Terrace Park: ****Viola ×brauniae* Grover ex Cooperr., Michigan Bot. 25:108. 1986 [= *Viola rostrata* Pursh × *V. striata* Aiton].

HARDIN COUNTY

THE EAST-WEST TRANSITION OF THE FLORA IN TEXAS: A BIOGEOGRAPHICAL ANALYSIS

Michael H. MacRoberts and Barbara R. MacRoberts

ABSTRACT

Quantitative methods were used to determine the transition zone between the eastern and western flora in Texas. The transition between the southeastern deciduous/coniferous forest region and the western plains/brushy-savanna is a 300 km wide area extending from around 95 degrees to 99 degrees west longitude. Across this area, eastern and western species drop out precipitously; this area is the range edge for the two floras. This finding agrees closely with earlier vertebrate biogeographic analyses.

KEY WORDS: West Gulf Coastal Plain, flora, biogeography, east-west floristic transition, Texas

RESUMEN

Se usaron métodos cuantitativos para determinar la zona de transición entre la flora oriental y occidental en Texas. La transición entre la región sur oriental de bosques deciduos/coníferas y la occidental de llanuras/sabana arbustiva es un área de 300 km de ancha que se extiende desde unos 95 grados a 99 grados de longitud oeste. A través de esta área, las especies orientales y occidentales se separan precipitadamente; esta área es el extremo del rango de las dos floras. Este hallazgo concuerda en gran medida con análisis biogeográficos realizados previamente.

INTRODUCTION

Despite the fact that the North American coastal plain is one of the continent's major floristic provinces (Dice 1943; Takhtajan 1986), quantitative papers on its phytogeography are poorly represented in the botanical literature (Sorrie & Weakley 2001). Even more poorly represented are such papers on the West Gulf Coastal Plain (MacRoberts et al. 2002; MacRoberts & MacRoberts 2003). While several quantitative studies are now available on endemism within the coastal plain (Sorrie & Weakley 2001; MacRoberts et al. 2002), studies on diversity, species richness, dispersion barriers, and floristic boundaries are lacking (Currie 1991; MacRoberts & MacRoberts 2003).

It has been long known that the eastern part of the West Gulf Coastal Plain (east Texas, south Arkansas, west Louisiana, southeast Oklahoma) is part of the eastern and notably the southeastern United States (Thorne 1993; Christensen 2000; Delcourt & Delcourt 2000), but it is unclear where the floristic east-west

transition occurs. An examination of the ecoregional literature indicates a rather confused picture of this transitional area (MacRoberts & MacRoberts 2003).

The purpose of this paper is to determine where floristic east meets west in the West Gulf Coastal Plain.

METHODS

1) In order to obtain a characteristic sample of the southeastern flora at the same latitude as Texas, we used Kartesz and Meacham (1999) to determine the distribution of all North American vascular plants whose distribution includes Georgia, Florida, Alabama, and Mississippi (although not necessarily restricted to that area) and that cross the Mississippi River into Louisiana and/or Texas (although not necessarily restricted to that area). Thus, species restricted to only the above listed states are included (e.g., *Xyris drummondii* Malme) as well as those found in all of the contiguous 48 states and Canada (e.g., *Potamogeton pusillus* L.). Exotic species and hybrids are excluded. Subspecies and varieties are lumped with species. Species whose taxonomic status or distribution was questionable are excluded. Our initial data set contained 1320 species.

Since there is no thorough county-by-county floristic inventory of the West Gulf Coastal Plain, we used a single source of data, which consists of samples from those counties. We plotted the distribution of species that met our criterion by Texas counties using the Texas Consortium database (TAMU-BWG Herbarium Specimen Browser, a consortium of seven Texas herbaria with 130,000 records online). Of the 1320 species in the initial data set, 1138 were in the TAMU database by county. In the preliminary analysis all data were converted to percentages because the counties have been unevenly collected and reported. Thus, Bowie County had 489 species in the TAMU database, of which 302 were from our data set (302/489 = 0.62) and Madison Co. had 1016 species, of which 452 were from our data set (452/1016 = 0.44).

2. In order to do the same thing but from a west-to-east perspective, we sampled the western flora by roughly the same methods as described above. Because both New Mexico and Mexico border Texas on the west, we selected three counties in west Texas (Taylor, Tom Green, Edwards), listed the species found in them from TAMU data base, and randomly selected 313 from the list on the basis of their western affinity (found in west Texas, New Mexico and/or Mexico [TAMU; Kartesz & Meacham 1999]). We used a much smaller sample from the west because we realized that the eastern sample was larger than necessary. Because the sample is smaller, to make numbers comparable with the east we multiplied the percentages by 2.

We then converted all of the county data in 1 and 2 above to the Owen and Schmidly (1986) quadrat system for Texas to standardize area and to even out irregular county boundaries and percentages. This also allowed us to use Owen and Schmidly's data on environmental variables of biological importance. The

quadrats are 63.9 km on a side, overlaid on a Lambert's conical projection map of Texas. We converted the county data to quadrat data by overlaying the quadrat map onto our county map and then averaging the percent of species of the counties that occurred in each quadrat.

3) Having found a clear east-west transition zone from the results of numbers 1 and 2 (see below), we wished to document the floristic affinities of Texas along an east-west gradient more thoroughly. To do this, we selected four Texas counties (Tyler, Madison, Bell, Irion) running across Texas at approximately 31 degrees North latitude and sampled them to determine their floristic relationship to the surrounding states. Using the TAMU database, we selected a random list of between 200 and 250 native species from each county. We then plotted the United States/Canada distribution of all species in the four lists using Kartesz and Meacham (1999). As before, the results are expressed as percentage of the sample (e.g., Louisiana had 97 percent of the species in Tyler County).

RESULTS

Figure 1 shows the percentage of eastern and western species in samples according to longitude across Texas. Figure 2 shows these data summarized for Owen and Schmidly (1986) quadrats by ten percent intervals. Figure 3 shows the distribution across North America of the flora of four Texas counties.

DISCUSSION

An examination of the shape of the curves in Figure 1 and the gradient expressed in Figure 2 shows that along Texas' 1250 km east-west axis, the area of most significant change in eastern and western species is the approximately 300 km wide zone from Houston and Tyler on the east (approximately 95 degree W. longitude) to Wichita Falls and San Antonio on the west (approximately 99 degrees W. longitude). On either side of this area, the change is gradual. According to our analysis, Fort Worth, Austin, and Corpus Christi appear to be the point at which east and west are balanced (97 degrees West longitude).

The relationship between county affiliation in the broader context of the entire North American continent north of Mexico shows the same pattern. Tyler County in east Texas is floristically eastern. Madison County farther west is mainly eastern, Bell County in the center of the transition zone is intermediate, and Irion County in the west is western (Fig. 3).

While ours is not a study of species richness, ecoregion boundaries, or diversity, nor is it concerned with cause of the species transition, it has implications for such studies. For example, Currie (1991) in a study of species richness has shown that the east-to-west loss of tree species across the gulf coastal plain correlates most strongly with actual evapotranspiration, which is correlated with primary production and is, therefore, a measure of available environmental energy.

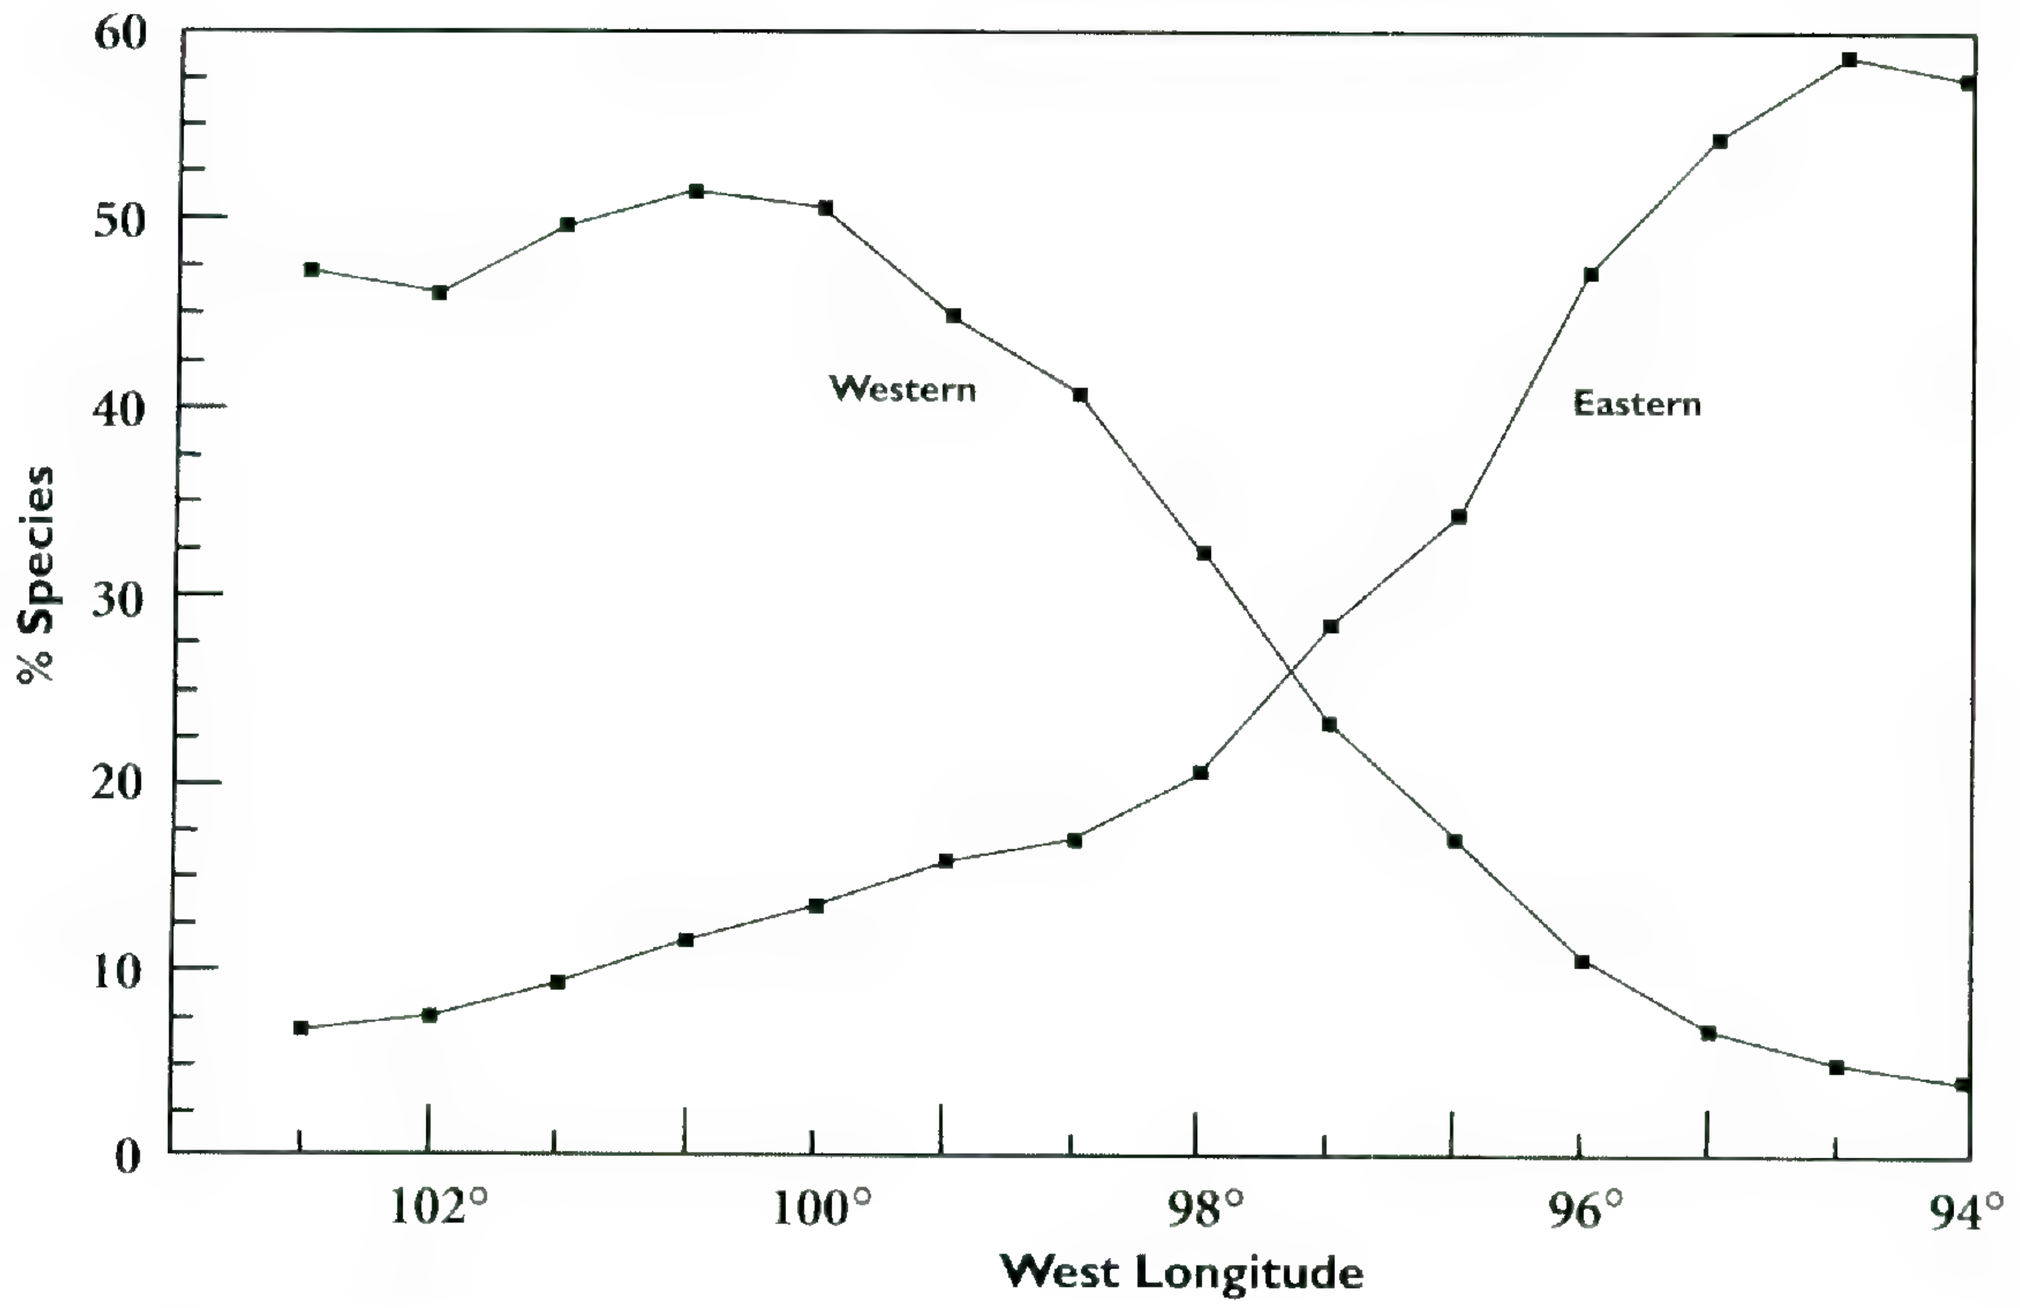

FIG. 1. Percentage of eastern and western species in samples according to longitude across Texas.

Our study also indicates that similar variables are important in determining species distribution in the West Gulf Coastal Plain. Using Owen and Schmidly's (1986) data, we calculated the correlation coefficient of "productivity" for eastern and western species and found a strong correlation between productivity across Texas and the number of eastern and western species. Eastern species correlated positively (Pearson = 0.91, Spearman = 0.92) while western species correlated negatively (Pearson = - 0.82, Spearman = - 0.77). The transition zone between east and west is after all the precipitation transition zone as well.

Central Texas has long been known to be an east-west transition zone, at least for vertebrates (Blair 1950; Webb 1950; Gehlbach 1991; Ward et al. 1994; Schmidly 2002). Dice (1943) referred to this area as the "Texan Biotic Province" between the eastern forest region ("Austroriparian") and the semi-arid brushy/savanna-grasslands ("Comanchian") of the western part of Texas. Blair (1950) recognized that the "Texan" was a "transitional region"—even using the word "ecotone"—but could find no alternative but to keep it a distinct province. Gehlbach (1991) solved the problem simply by pointing out that central Texas is a transition zone, not a biotic province, between the eastern deciduous forest region (Austroriparian Biotic Province) and western semi-arid brushy-savanna region (Comanchian Biotic Province). Characteristic plants and animals of both the Comanchian and Austroriparian occur locally in the Texan. More recently, Diggs et al. (1999:4) have characterized north central Texas floristically as "a

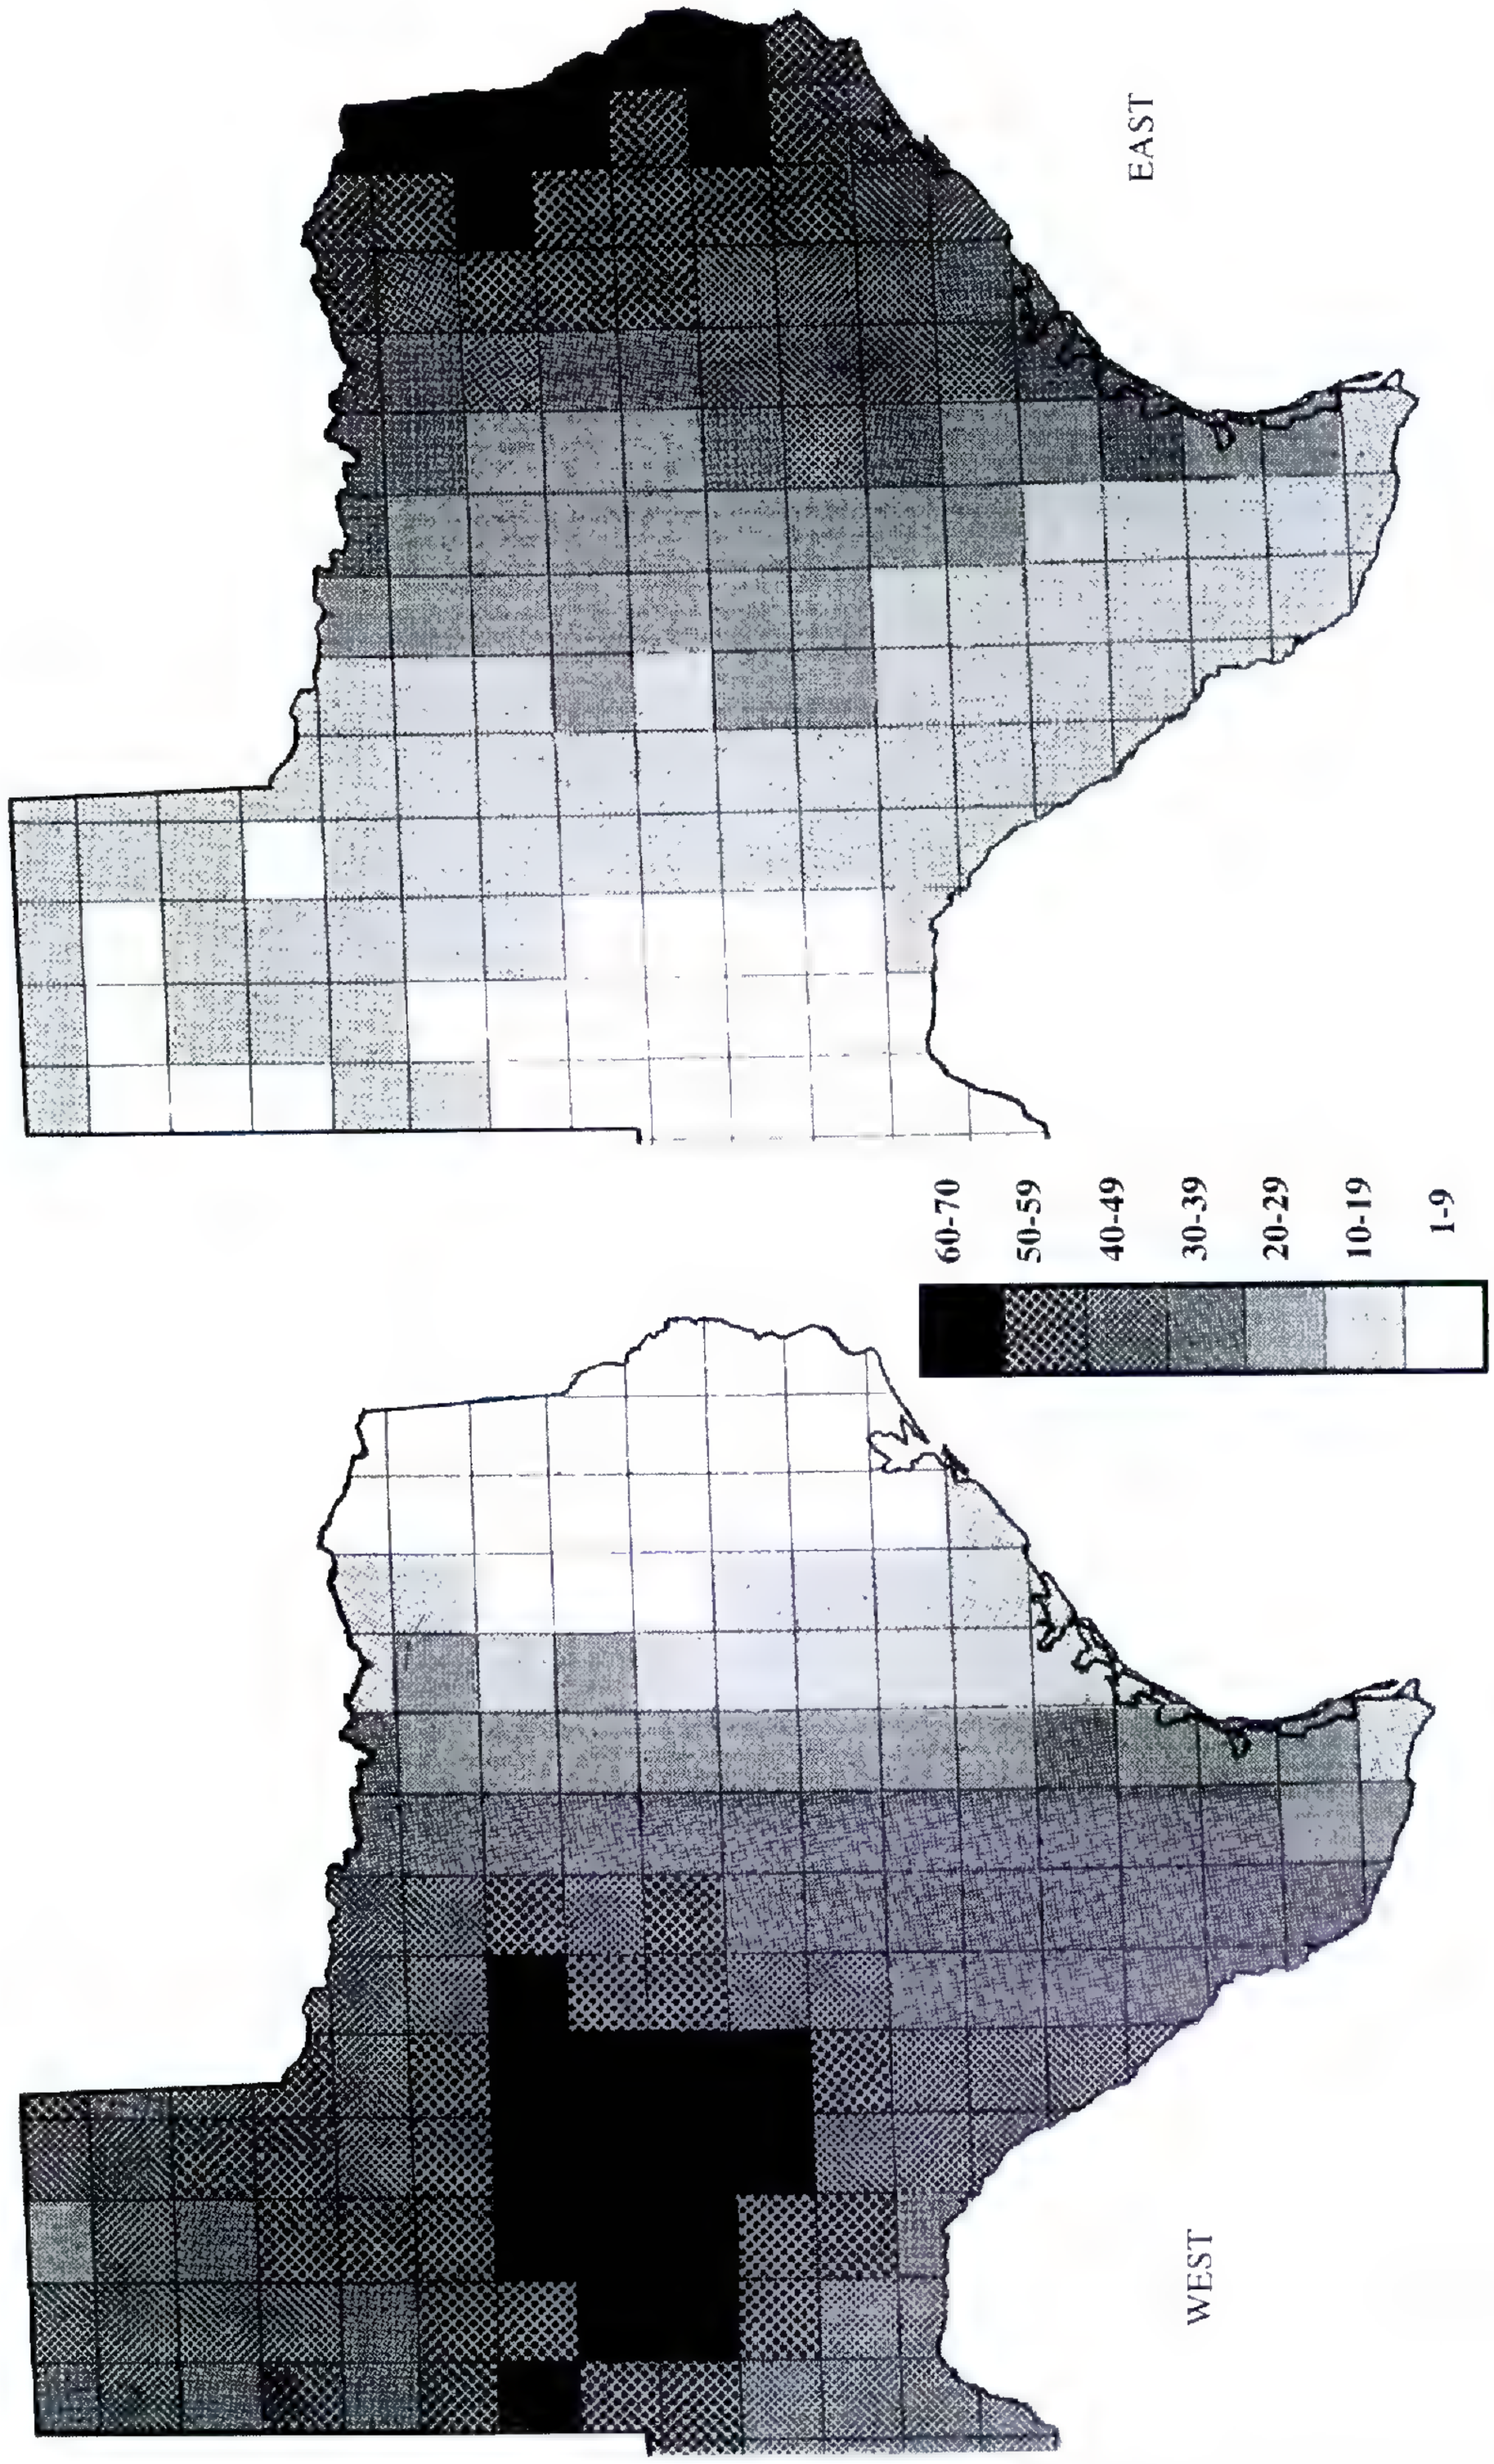

FIG. 2. Percentage of eastern and western species in samples according to Owen and Schmidly (1986) quadrat system at ten percent intervals.

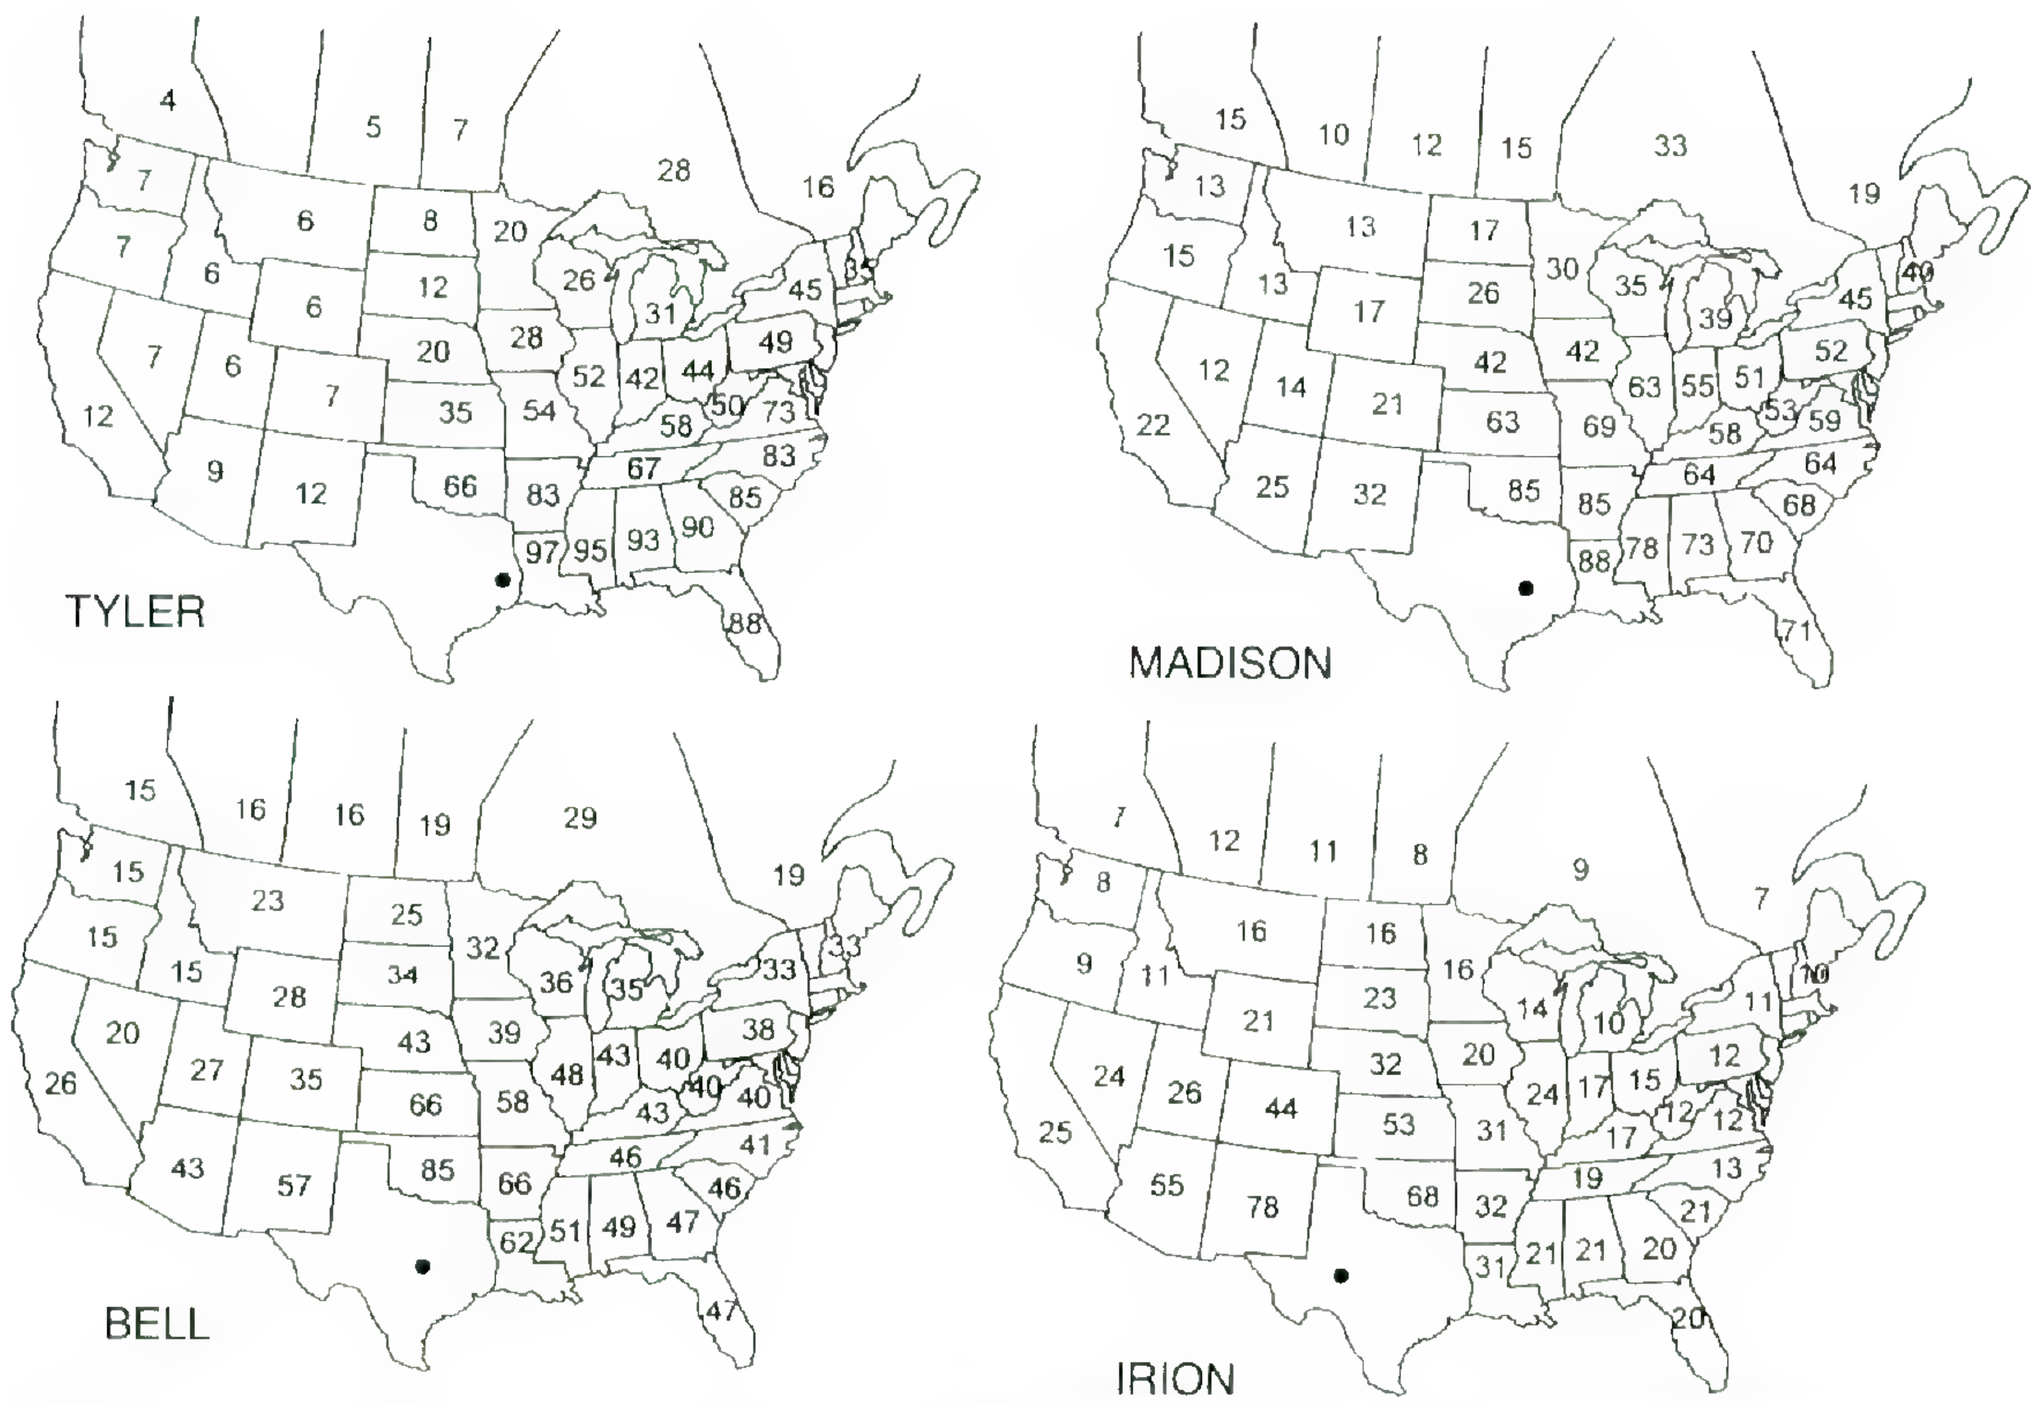

FIG. 3. Percentage of states, provinces, and geographical areas having species in samples from Tyler, Madison, Bell, and Irion counties, Texas.

broad ecotone between eastern deciduous forest and western grassland." We concur with these characterizations. From a floristic perspective, there is an east-west transition in the area roughly designated as Texan Biotic Province.

Paleoenvironmental studies indicate that the current floristic character of Texas may be fairly recent. Pleistocene and Holocene climatic changes appear to have been significant with the invasion of the West Gulf Coastal Plain by southeastern and Mexican species since the last glacial retreat (Bousman 1998; Delcourt & Delcourt 2000).

We do not consider our overall findings particularly novel. Years ago, zoologists came to basically the same conclusions based on vertebrate distribution. West Gulf Coastal Plain botanists, however, have been slow to address biogeographic questions quantitatively. As a result, botanists and botanically inclined ecologists have created a plethora of qualitatively defined "ecoregions" across Texas (Webb 1950; MacRoberts & MacRoberts 2003). We believe that zoologists currently have a better understanding of the biogeographic regions of Texas than do botanists, but improved plant distributional data (e.g., Turner et al. 2003) and the replacement of qualitative by quantitative methods of investigation should soon provide botanists with the opportunity to rectify this situation. With better data, and thus the ability to make finer comparisons, it will

be interesting to see just where the transition is most pronounced and how west and south Texas separate from the remainder of Texas and the southeast.

ACKNOWLEDGMENTS

Laurence M. Hardy aided with the figures. Bruce Sorrie commented on an earlier version of the paper. Thanks also to Guy Nesom and Fred Gehlbach for their reviews of the manuscript.

ABSTRACT

During recent botanical explorations of Saurashtra, Gujarat, India, the narrowly endemic plant species *Tephrosia jamnagarensis* was rediscovered after a lapse of 3 decades. A full description of the species is provided along with photographs; a key to closely related species is included.

RESUMEN

Durante exploraciones botánicas recientes en Saurashtra, Gujarat, India, la especie endémica *Tephrosia jamnagarensis* fue redescubierta después de un intervalo de tres décadas. Se ofrece una descripción completa de la especie junto con fotografías y se incluye una clave para las especies relacionadas más próximas.

INTRODUCTION

During a floristic survey of Jamnagar District (Nagar 2002), *Tephrosia jamnagarensis* Santapau—an endangered and endemic species of Saurashtra (Kothari & Hajra 1983; Nayar & Sastry 1988; Santapau 1958; Shah 1983)—was collected from the lower slopes of the Khad Khambhaliya Vidi (Grassland), Lalpur Taluka, Jamnagar District, Gujarat, India. Fieldwork in 2001 verified the occurrence from Jamnagar District, though not from the same locality.

Tephrosia jamnagarensis was not recognized as a distinct species in earlier floras of the state (Cooke 1901–1903; Thaker 1910). The specific epithet *jamnagarensis* refers to the type locality.

The species was collected for the first time by Santapau (*Santapau 7522*) near Rozi, Jamnagar District, Gujarat, India in 1945 (Santapau 1958) and for the second time some 11 years later (24 Aug 1954) from Victoria Bridge, Jamnagar District (Santapau 1962). A few plants were collected in 1972 from wastelands near the cultivated fields of Bhadbhut, close to Bharuch (South Gujarat), a different sub-humid geographical region (Shah 1978; Vyas 1973). A recent survey

for T. *jamnagarensis* in these same locations did not locate it. The areas have been mostly converted to agricultural land (Nagar 2000; Rao 2002). The recent collections of *T. jamnagarensis* represent not only the rediscovery of this very interesting taxon—after a gap of almost 3 decades—but are also the first available collections that allow for a full description of the flower.

With this recent collection in flower and fruit, a detailed description of the species with floral characteristics, phenology, and habit and habitat distribution is given; photographs are provided.

DESCRIPTION OF *TEPHROSIA JAMNAGARENSIS* AND ITS COMPARISON WITH *TEPHROSIA STRIGOSA*

Tephrosia jamnagarensis Santapau in Proc. Natl. Inst. Sci. India 24B:133, t. 1. 1958. (**Fig. 1**). TYPE: INDIA. GUJARAT. Jamnagar District: near Rozi, 16 Oct 1945, *Santapau 7522* (HOLOTYPE: BLAT).

Erect or suberect, annual herb; stems simple or sparsely branched, covered with whitish appressed hairs. Leaves simple, 3–5.2 × 5–9 mm, linear, glabrous adaxially, densely hairy with silvery appressed hairs abaxially, subobtuse and clearly apiculate at apex, acute at base; lateral nerves 25–30 pairs, parallel; margin entire, with a nerve running from near the base to the apex very near the margin; the nerves covered with hairs, distinct on the adaxial surface, equally distinct on the abaxial surface. Petioles 2–3 mm, hairy; stipules subulate, 3–4 mm, hairy. Flowers single or in pairs, axillary; pedicels 2–3 mm, about as long as the petioles, densely hairy. Calyx, 1–3 mm, hairy, the teeth subulate, filiform, subequal. Corolla mauve, 2.5–3 mm (standard 3 mm, wings 2–2.5 mm, keel 2.5 mm). Legumes compressed, ca. 20 × 5 mm, densely and patently hairy with grayish tinge, oblique at both ends, apiculate; seeds 5–6, reniform, dull or matt, brownish.

Tephrosia jamnagarensis is similar to *T. strigosa* (Dalz.) Sant. & Mahesh, differing mainly by its broader (twice as broad as in *T. strigosa*), densely pubescent pods and by its larger leaves with densely appressed hairs on the abaxial surface, which is clearly silvery or densely argenteo-canescent, making it very distinct from *T. strigosa*. The pedicels are shorter and stouter than in *T. strigosa*. The seeds are not separated by any internal partition (partitioned in T. *strigosa*).

Voucher specimens: **INDIA. Gujarat. Jamnagar District:** Lalpur Taluka: Khad khmbaliya Vidi (Grassland), 17 Oct 2001, *P.S. Nagar 1221, 1222, 1234, 1235* (SAUUNI= Saurashtra University).

Additional specimens examined: **INDIA. Gujarat. Jamnagar District:** near Rozi, 16 Oct 1945, *Santapau 7522* (HOLOTYPE: BLAT); Bhadbhut, 12 Oct 1972, *K.J. Vyas 3095* (spu); Bharuch, 18 Sep 1972, *K.J. Vyas 2664* (spu); 21 Sep 1972, *K.J. Vyas 2946* (spu). Specimens other than the holotype are deposited in the herbarium of Department of Biosciences, Sardar Patel University (spu), Vallabhvidyanagar, Gujarat, India.

Phenology and Associated Species.—The plants were in flower from September to October, in fruit, from October to November. They grew in grassland with

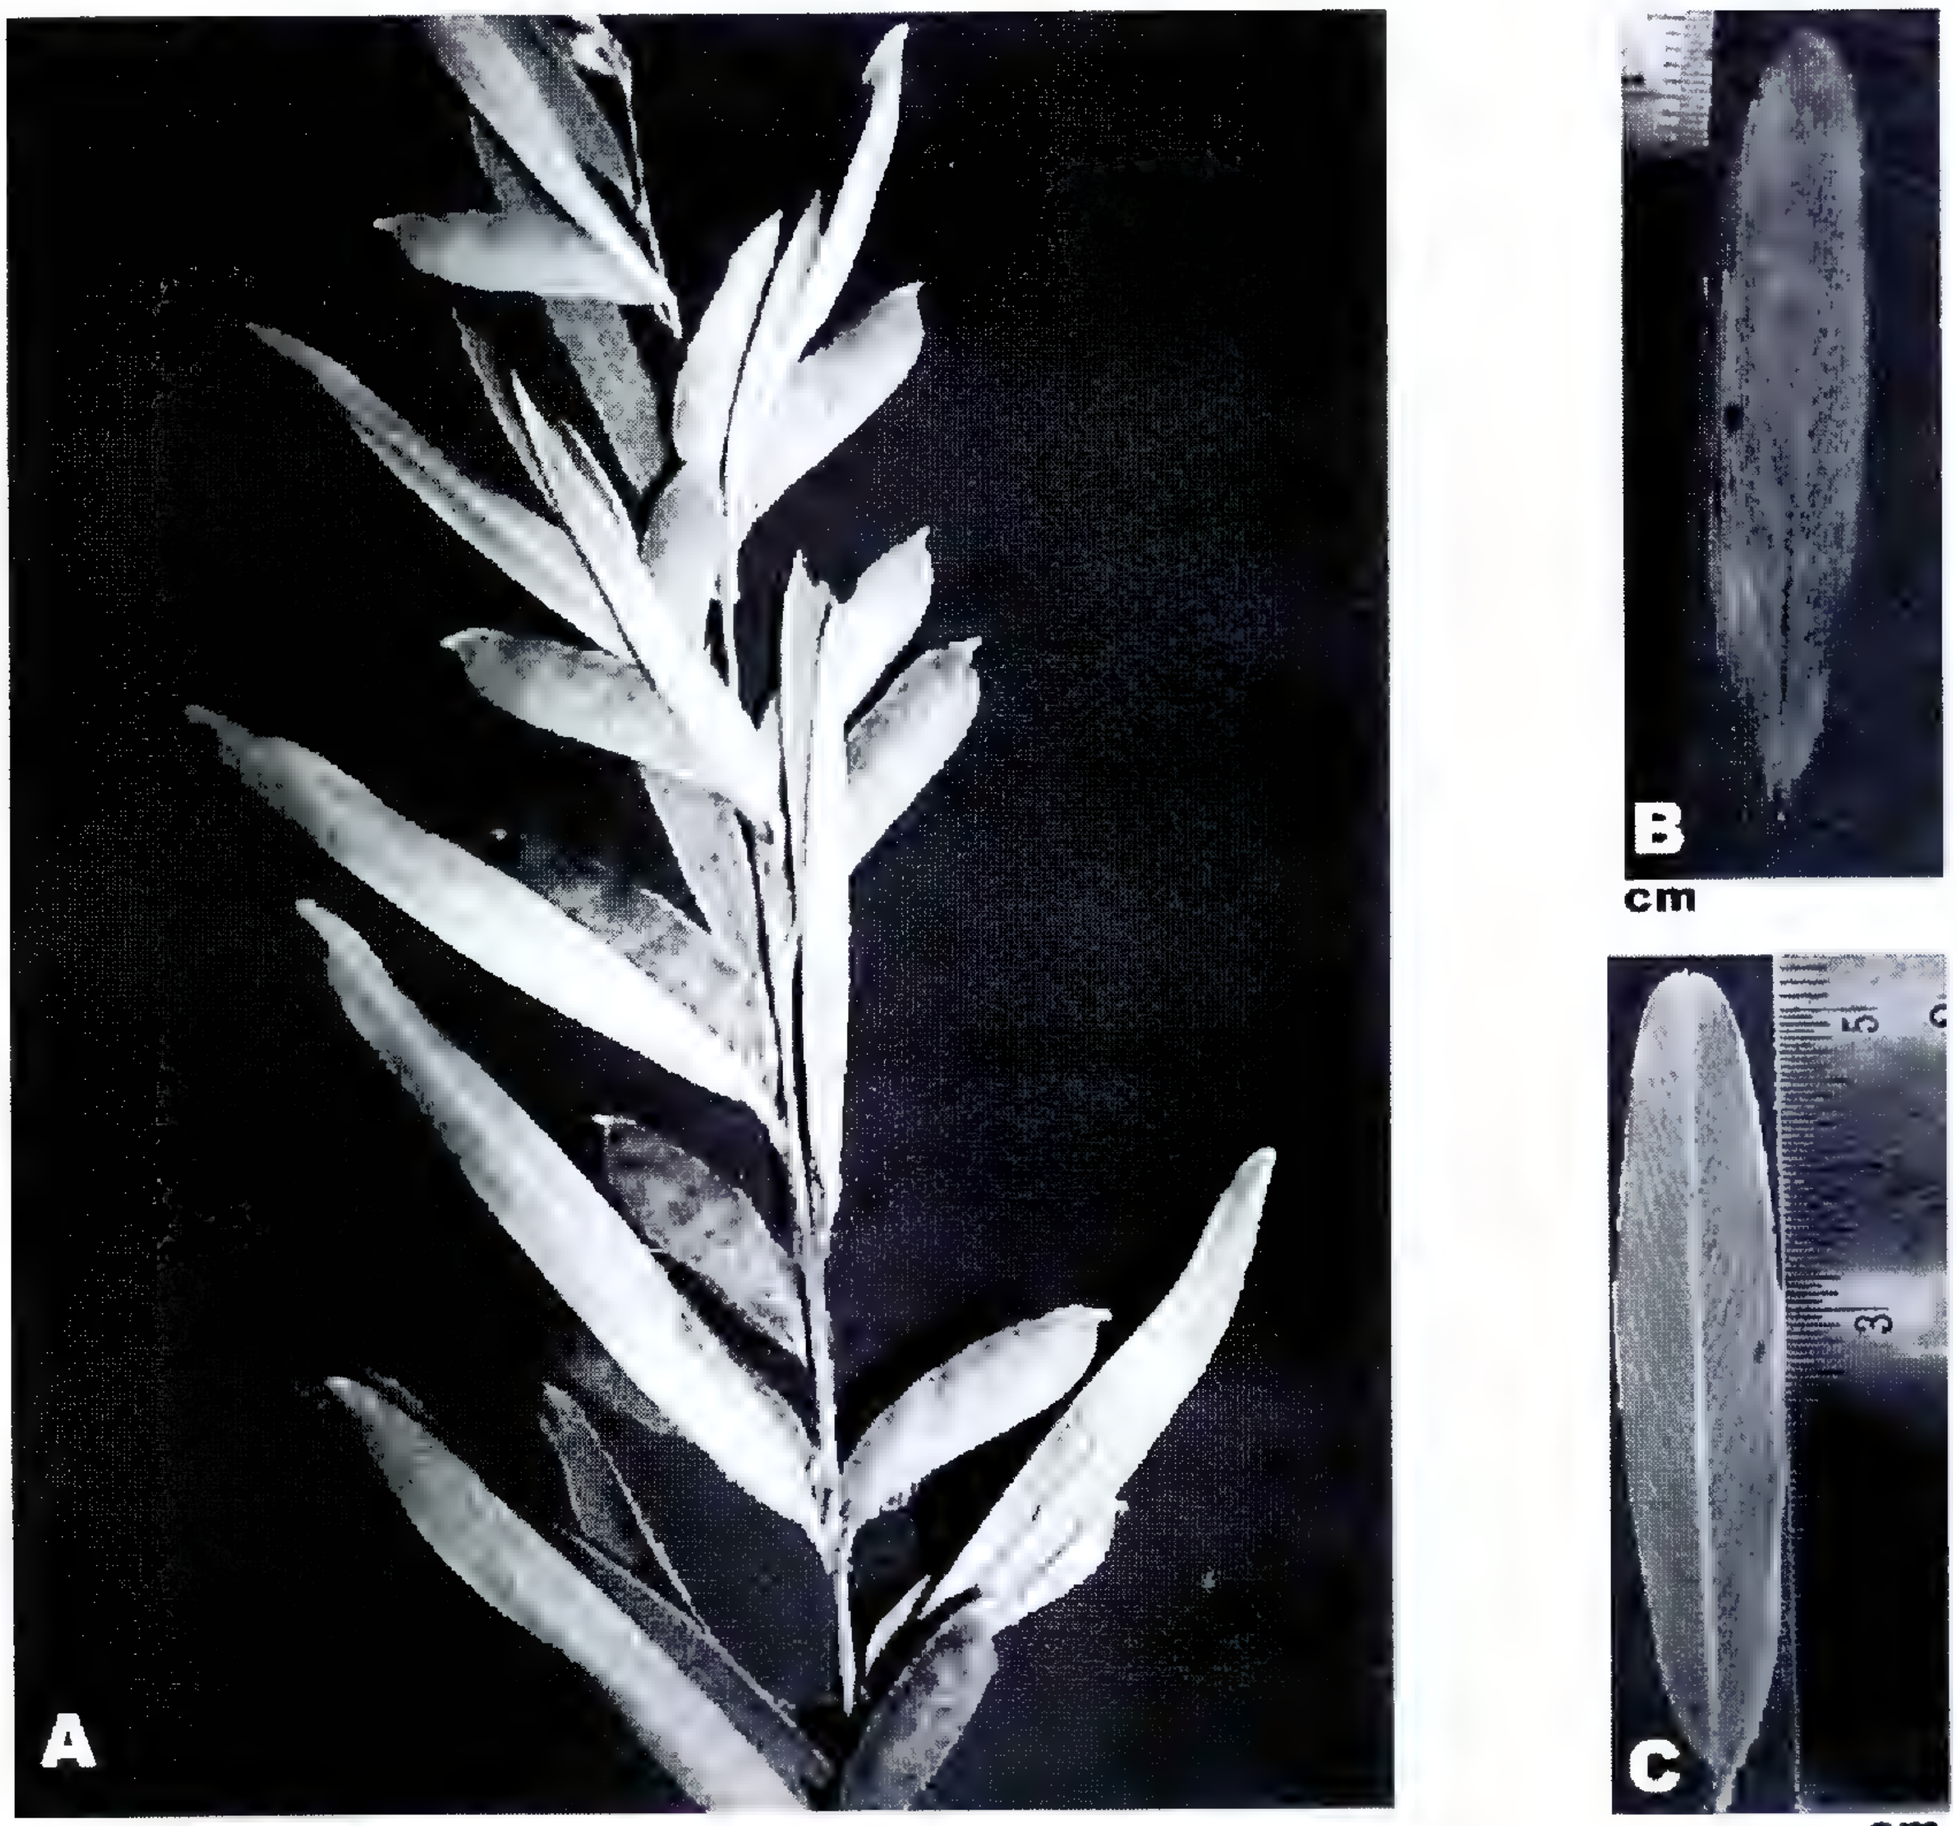

FIG. 1. *Tephrosia jamnagarensis* Santapau **A.** Habit, Leaf; **B.** Adaxial surface; **C.** Abaxial surface; **D.** Flowering twig; **E.** Calyx; **F.** Ovary; **G.** Pod; **H.** Seed ornamentation; **I.** Seeds.

Chrysopogon fulvus (Spr.) Choiv., *Sehima nervosum* (Rottl.) Stapf, *Hetropogon contortous* (L.) P. Beauv. ex R. & S., *Aristida sp.*, *Borreria stricta* (L.f.) K. Schum, *Zornia diphylla* auct., *Indigofera cordifolia* Heyne ex Roth, *Indigofera tinctoria* L., and *Alysicarpus vaginalis* (L.) DC.

Habitat and Population Status.—The plants were growing on calcareous gravelly soil. The species is very rare. A quantitative analysis of the population indicated an estimated density of 0.24 plants/m^2 and frequency of occurrence of 6% (India: Gujarat. Jamnagar District. Khadkhambaliya Region, Lalpur Taluka (Nagar 2002). The rarity of the plant is probably due to overgrazing, habitat destruction, lack of protection, and probably other biotic factors. The plant has been listed as rare under threat category (Botanical Survey of India 1993; WCMC 1994).

Distribution.—The geographical range of *T. jamnagarensis* Sant. is restricted to two separate regions: the western group of populations in northwestern Jamnagar (Rozi and Khadkhambaliya) and the southern population in southwest Bharuch.

Potential Value.—Several species of *Tephrosia* [e.g., *T. purpurea* (L.) Pers.] are sometimes grown as green manure and as cover crops (Santapau 1962); *T. purpurea* is useful medicinally [the whole plant is used internally as purgative, laxative, and tonic; externally it is applied on skin boils (Thaker 1910)]. It is likely that *T. jamnagarensis* may also have similar properties.

ACKNOWLEDGMENTS

ABSTRACT

Plants previously considered *Polygonum patulum* Bieb in California are within the range of variation of *Polygonum ramosissimum* Michx. complex. The real *Polygonum patulum* is recorded now for the first time from Alabama, Illinois, Utah and Washington, where it has occurred as a rare ruderal.

RESUMEN

Las plantas consideradas previamente *Polygonum patulum* en California se encuentran dentro del rango de variación del complejo de *Polygonum ramosissimum*. El verdadero *Polygonum patulum* es citado ahora por primera vez en Alabama, Illinois, Utah y Washington, donde ha aparecido como un ruderal raro.

The Eurasian and North African *Polygonum patulum* M. Bieb. has been listed in all standard Californian floras (e.g., Munz & Keck 1968; Hickman 1993). However, Hickman (1993) noted that the "applicability of this name to Californian plants remains uncertain." After comparing these plants with the European specimens of *P. patulum*, we can confirm that they do not belong to this species. The Californian plants resemble *P. patulum* in having a terminal spiciform inflorescence (with the leaves in the upper part of inflorescence reduced to bracts which are shorter than the flowers they subtend) and small flowers and fruits of 2.5–3 mm, and 2.2–3 mm, respectively. However, the achenes of *P. patulum* are striate-tubercled, and the inner and outer tepals have about the same length. Plants from California have smooth to roughened achenes, and the inner tepals are evidently shorter than the outer tepals. Many of these plants are identical to some of the specimens quoted by Small when he described *P. exsertum* (Small 1894): **United States of America**. **Missouri:** St. Louis, Sep 1845, *G. Engelmann s.n.* (NY). **NEBRASKA**: Valentine, 1891, *J.M. Bates s.n.* (NY). Unfortunately, the protologue and the subsequent descriptions of *P. exsertum* have placed emphasis only on the much elongated late-season achenes, which are taxonomically irrelevant (e.g. Fernald 1950). The morphology of the perianth and achenes during early summer has been not explored. Consequently, *P. exsertum* has been considered by all the authors to be a synonym of *Polygonum ramosissimum* (e.g. Gleason 1952; Mertens & Raven 1965; Wolf & McNeill 1986).

[1]Corresponding author.

Polygonum ramosissimum is a complex species similar in that regards to *P. aviculare* (Costea & Tardif 2003). *Polygonum exsertum* and possibly other species previously synonymized with *P. ramosissimum*, may deserve taxonomic recognition as infraspecific taxa of *P. ramosissimum*. Nevertheless, further research is needed to understand the patterns of variation within *P. ramosissimum*. For the time being, it is safe to conclude that what has been considered *P. patulum* in California is within the range of *P. ramosissimum* variation.

The real *P. patulum* is a rare adventive in North America. During the preparation of the genus *Polygonum* for Flora of North America we have found only a few collections in the United States of America that can be ascribed to this taxon, and these are new floristical records. Except for *P. ramosissimum*, *P. patulum* may be mistaken only with *P. argyrocoleon* Steud. ex Kunze. The latter has smooth achenes and the terminal spiciform inflorescence is congested, dense, with cymes having 4–5 flowers. *Polygonum patulum* has striate-tubercled achenes, and the terminal inflorescence is open, with cymes having 1–4 flowers.

Typical specimens examined: **U.S.A. ALABAMA. Mobile Co.:** Mobile, adventive with ballast, Oct 1893, *C. Mohr s.n.* (NY). **ILLINOIS. Union Co.:** 4.3 mi S of Jonesboro, disturbed clay, rather common roadside weed, 23 Sep 1999, *S.R. Hill 32090* (NY). **UTAH. Uintah Co.:** NW corner of Pelican Lake, 1250 m, in moist soil of edge of lake, 8 Aug 1983, *E. Neese 14645* (NY). **WASHINGTON. Grays Harbor Co.:** Montesano, in fields, Sept 1917, *J.M. Grant* (NY).

ABSTRACT

The occurrence of *Polygonum aviculare* subsp. *rurivagum* in North America is confirmed. The taxon is a rare adventive from Europe growing in sunny, dry and trampled ruderal habitats.

RESUMEN

La presencia de *Polygonum aviculare* subsp. *rurivagum* en Norteamérica es confirmada. Es un taxon raro originario de Europa que crece en lugares ruderales, soleados, secos y pisoteados.

The occurrence of the European *Polygonum aviculare* L. subsp. *rurivagum* (Jord. ex Boreau) Berher in North America has been uncertain. Löve and Löve (1956) reported it from eastern North America but they did not indicate any location. Furthermore, their results have been generally disregarded because of some doubtful chromosome counts, and because no specimens or vouchers have been quoted or found (e.g., Mertens & Raven 1965; Wolf & McNeill 1986). During the preparation of the genus *Polygonum* for Flora of North America we have encountered this taxon in scattered locations in North America and we compared it with European material. Some relatively recent European floras and treatments of *Polygonum* have preferred to treat this taxon as a species (*P. rurivagum* Jord. ex Boreau, e.g., Akeroyd 1993; Do Amaral Franco & Da Luz Rocha Afonso 1995; Stace 1997) following the study of Styles (1962). Nevertheless, its classification under *P. aviculare* is apparently the best solution (Karlsson 2000; Costea & Tardif 2003). It is a rare but homogenous taxon. Its extreme morphology, with paucif lorous cymes (1–3 f lowers), small f lowers, 2.3–3.2 mm, and narrow-elliptic to linear-lanceolate leaves, 1.5–5 mm wide, brings it close to *P. aviculare* subsp. *neglectum* (Besser) Arcang., with which it has been frequently misidentified. The subsp. *rurivagum* differs by the long ochreas, 8–12.5 mm, with strong veins and the free part disintegrating into persistent fibers, and by the leaves with lateral veins strongly raised on the abaxial part of the leaves. The subspecies *neglectum* has ochreas of 4–8 mm, with inconspicuous veins and free part leaving almost no fibrous remains and leaves without strongly raised lateral veins. For differences between subsp. *rurivagum* and the other subspecies of *P.*

ABSTRACT

This report documents the occurrence and distribution of the *Uvularia perfoliata* and *U. sessilifolia* in the state of Texas. A key to species, notes, distribution (including a map), and a list of exsiccatae are presented.

RESUMEN

Se cita y se documenta la presencia y distribución de *Uvularia perfoliata* y *U. sessilifolia* en el estado de Texas. Se presenta una clave de especies, notas, distribución (incluyendo un mapa), y una lista de exsicatas.

Uvularia is a small genus of five species native to eastern North America from Nova Scotia and southern Quebec south to Florida and westward to Texas and North Dakota (Wilbur 1963; Utech & Kawano 2002). The plants are rhizomatous perennial herbs with leafy, forked aerial stems. Leaves may be sessile or perfoliate. Plants normally have one or occasionally two greenish or yellow flowers that are campanulate in shape.

Our objectives are to document knowledge of the expanded distribution of *Uvularia sessilifolia* and *Uvularia perfoliata* in eastern Texas, summarize the known history of both species within Texas, and provide a means of identifying the species in the state. The paper is based upon recent field studies conducted in the eastern portion of the state and examination of herbarium specimens from selected herbaria (ASTC, BAYLU, & TEX).

KEY TO THE SPECIES OF *UVULARIA* IN TEXAS

1. Leaves rounded at the base, perfoliate _____ **1. U. perfoliata**
1. Leaves narrowed at base, sessile, not perfoliate _____ **2. U. sessilifolia**

1. Uvularia perfoliata L.

Uvularia perfoliata is distributed from New England and Ontario south and westward to Florida, Texas and Arkansas (Wilbur 1963, Utech & Kawano 2002). Within Texas, the species is known from Sabine, Nacogdoches, Shelby, and San

SIDA 20(4): 1713–1716. 2003

Augustine Counties (Fig. 1), a distribution that is basically contiguous with the distribution in Louisiana presented by Thomas & Allen (1993). The species occurs in mixed beech-maple series hardwood forests.

Brown (1972) first mentioned the occurrence of *Uvularia pefoliata* in Texas but provided neither specific location nor other documentation. Brown made trips to rich woodlands in eastern Texas and was generally consistent about making vouchers for his photos, but he either failed to do so in the case of *U. perfoliata* or the collection was lost or destroyed (Mark Mayfield, pers. comm.). The first documented record of this species in the state was Nixon and Damuth's (1987) report for Sabine County. In 1989, Bridges and Orzell presented an account of the species in Texas, citing seven collections, all from Sabine County. Turner et al. (2003), in the *Atlas of Vascular Plants of Texas*, illustrate the distribution of the species as being Sabine, Shelby, and St. Augustine counties. The species is reported as occurring in Nacogdoches County for the first time.

In addition to distinctive perfoliate leaves, the species is characterized by short 1 cm long rhizomes, scarious smooth-margined leaves, and terete hollow aerial stems. In the following list of exsiccatae, only one specimen per county is cited

Specimens examined: **Nacogdoches Co.:** 6 mi ENE of Cushing, upper spring creek drainage that drains into Barnes Lake, Apr 1994, *Singhurst 4912a* (BAYLU). **Sabine Co.:** 4.1 mi E of Geneva, 22 Mar 1985, *Nixon 14347* (ASTC). **San Augustine Co.:** 0.7 air mi NW of Black Ankle, Sabine National Forest, Tenaha Ranger District, Compartment 65, 12 Apr 1989, *Orzell 9209* (TEX). **Shelby Co.:** 0.3 air mi ESE of FM 2261 and FS Rd 106 jct in E Hamilton, Sabine National Forest, Tenaha Ranger District, Compartment 50, 12 Apr 1989, *Orzell 9261* (TEX).

2. Uvularia sessilifolia L.

The distribution of *Uvularia sessilifolia* extends from southern Canada (Ontario and Nova Scotia), south to Florida and west to Texas, Oklahoma, and North Dakota (Wilbur 1963; Utech & Kawano 2002). *Uvularia sessilifolia* has been documented in three locations in Newton County and one location in Jasper County (Fig. 1), approximately 280 km from the Cass County location cited in this paper, and 210 km from its nearest Louisiana record in Lincoln Parish (Thomas & Allen, 1993). The species occurs in moist hardwood and bottomland forests, but in more xeric sites than *U. perfoliata*. The distribution map of this species in Flora of North America (Utech & Kawano 2002) shows it occurring in extreme northeast Texas, perhaps Bowie or possibly Lamar and Red River counties (the small scale of the map prevents accurate determination of county), which all border Oklahoma and the Red River. Examination of specimens from these counties determined to be *U. sessilifolia* showed them to be immature and sterile specimens of *Polygonatum biflorum* (Walt.) Elliott. (Liliaceae), a species that is uncommon and sporadic where it occurs in east Texas. The Cass County specimen cited is the only report of the species outside of the longleaf pine region of southeast Texas (Newton and Jasper counties).

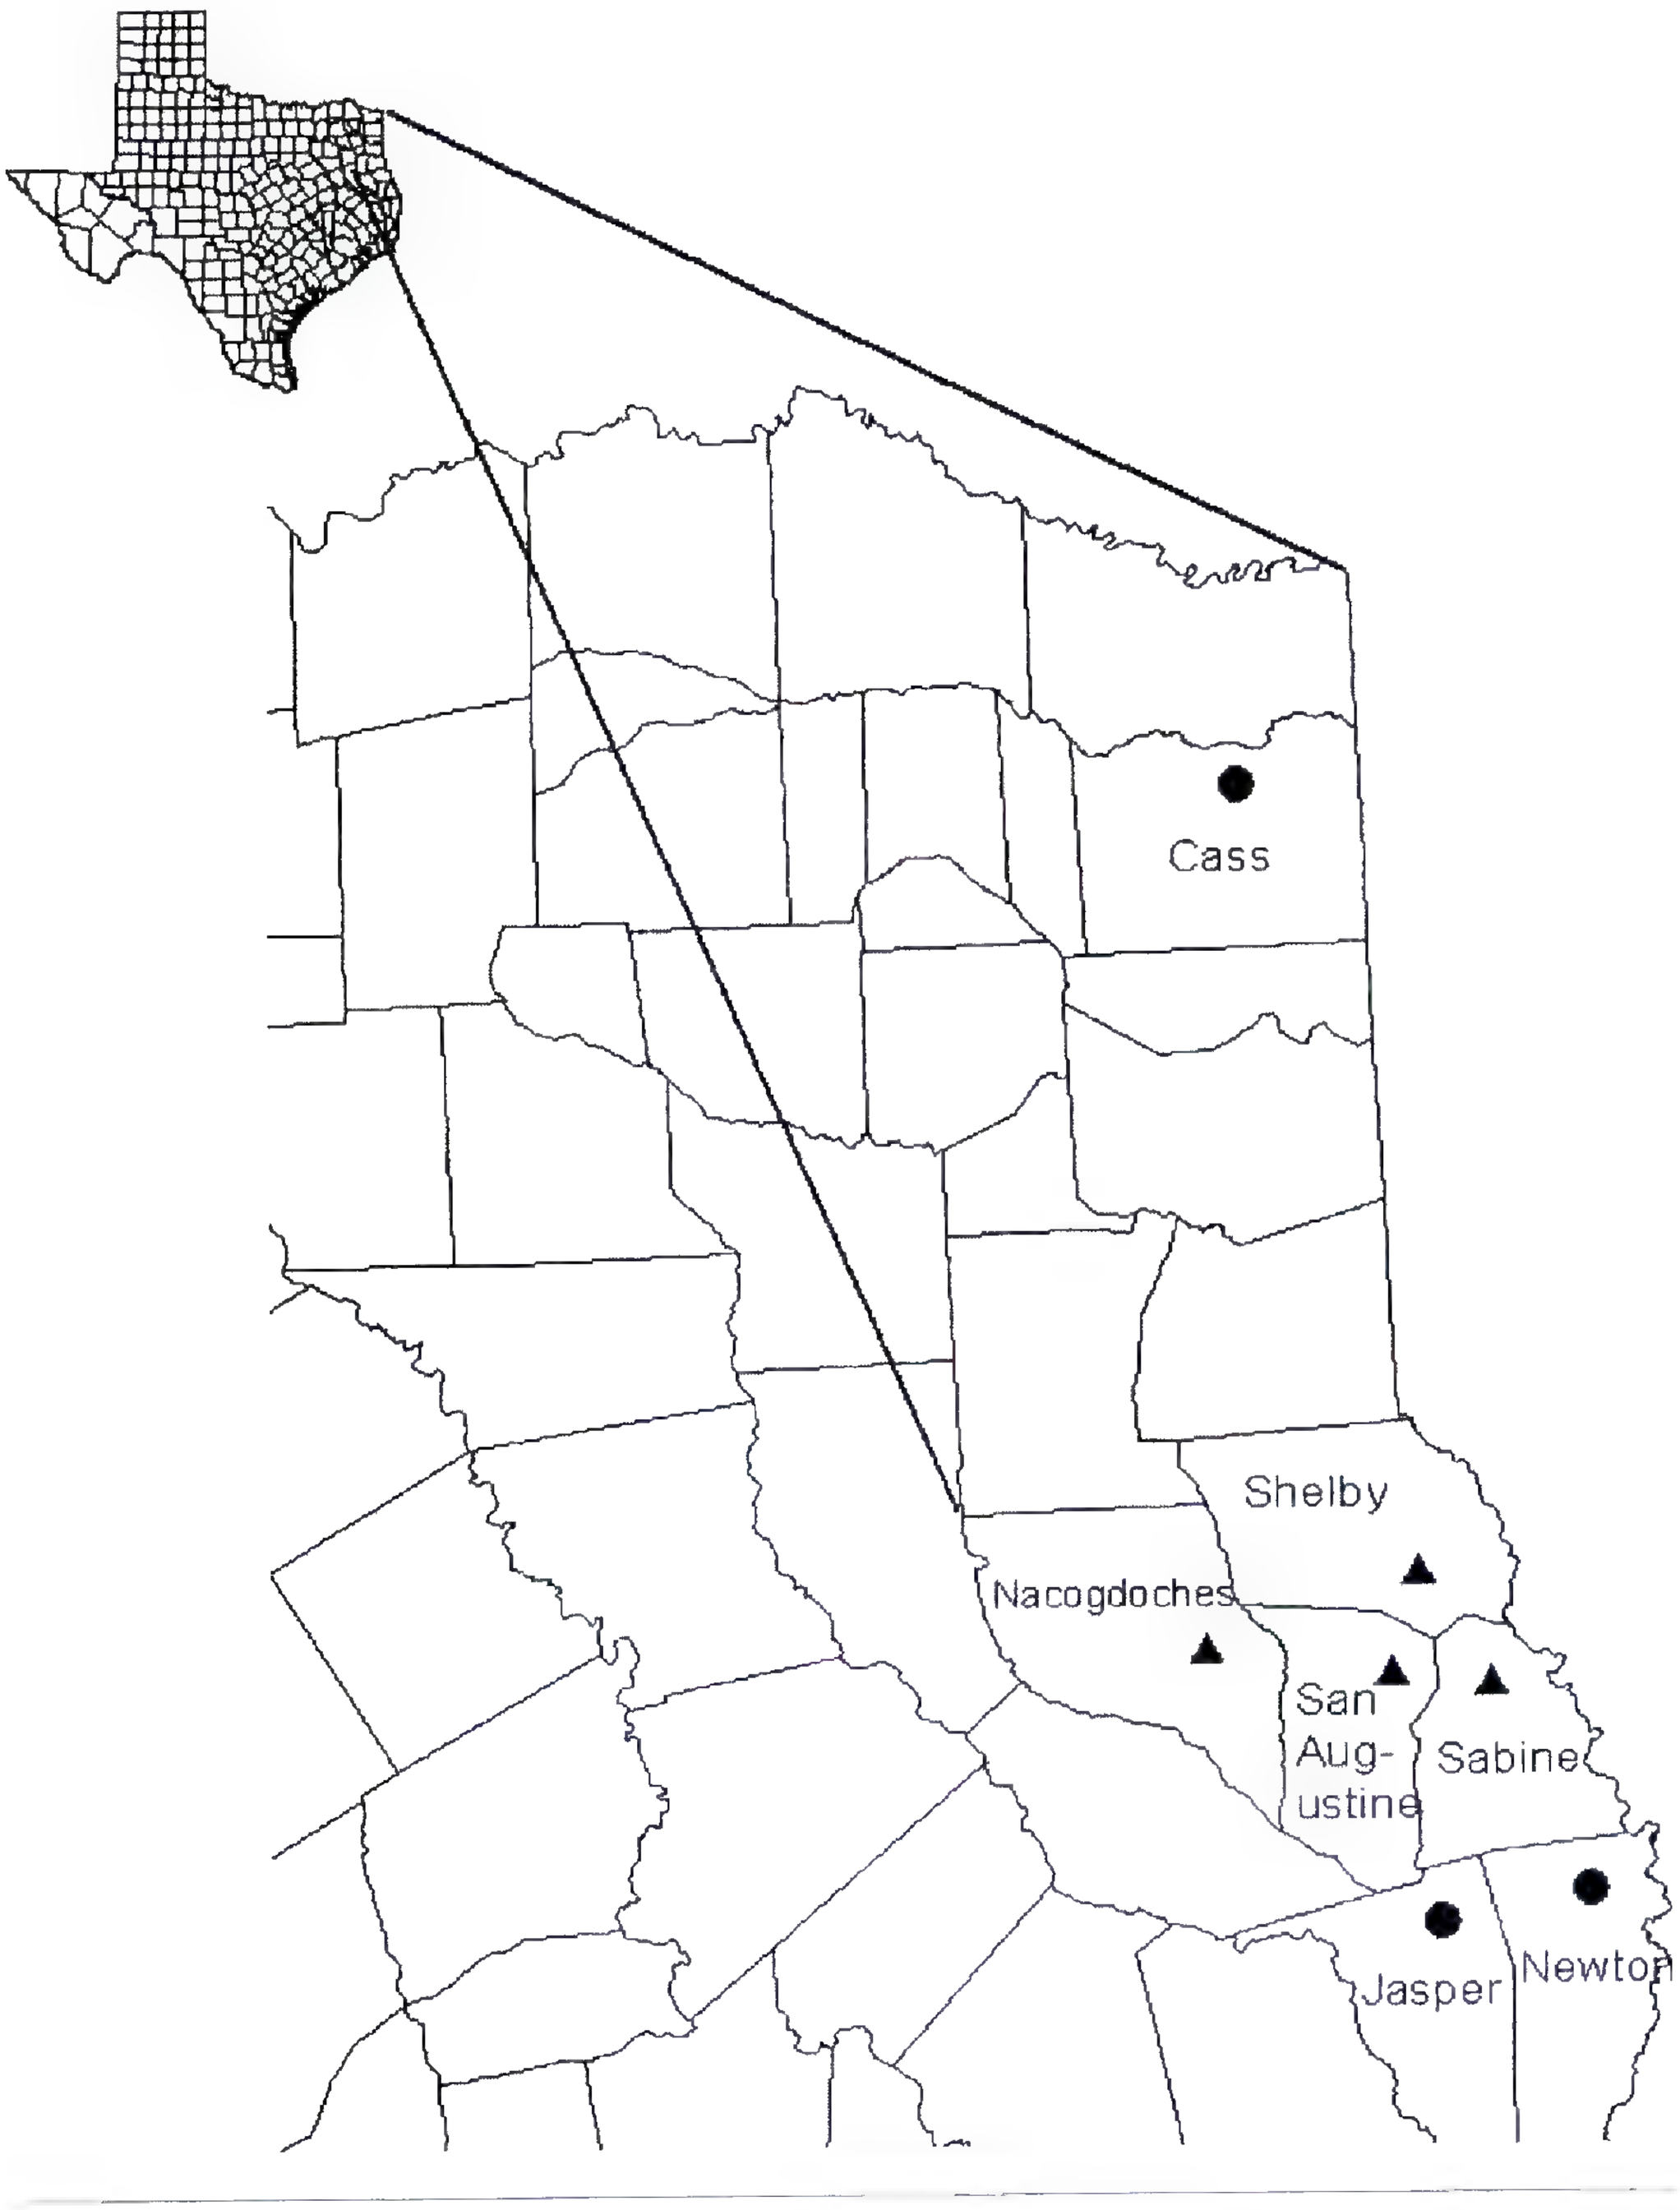

FIG. 1. Distribution of *Uvularia perfoliata* (triangles) and *U. sessilifolia* (circles) in Texas.

In addition to sessile non-perfoliate leaves, *Uvularia sessilifolia* can be distinguished from *U. perfoliata* by its longer rhizome of 10 cm or more in length, scarious margined leaves that are very finely serrulate, and aerial stems that are angled and solid. In the following citations of specimens, both the Cass county and Jasper County records are reported for the first time. Because of the

rarity of the species in the state, all collections are cited.

Specimens examined: **Cass Co.:** Atlanta State Recreational Area, base of Dogwood Trail at jct. of wood bridge, 9 Mar 2002, *Singhurst 11724* (BAYLU). **Jasper Co.:** Temple Inland Distinctive Site, Beef Creek, S of Rayburn Country, jct. of R255 and private forest road between Rayburn Country and Lake Sam Rayburn Dam, 1 mi S of forest road, 6 Mar 2002, *Singhurst 11213* (BAYLU). **Newton Co.:** Little Quicksand Creek on FM 1414 ca. 2.8 mi E of jct of Tex. Hwy 87 N of Newton, 3 Apr 1997, *Carr 15983* (TEX); Hickman Creek ca. 0.4 mi W of jct. with FM 645, 3 Apr 1998, *Singhurst 6591 & Watson* (BAYLU); Mack Creek, ca. 4 mi E of Newton on FM 1414, 4 Mar 2000, *Holmes 10795, Singhurst, & Caldwell* (BAYLU).

ACKNOWLEDGMENTS

We are grateful to Tom Wendt (TEX) for his assistance and Mark Mayfield (formerly of LSU, now of KSC) for information on the collections of Claire Brown We also acknowledge the cooperation of the United States Army Corps of Engineers for granting access to public lands near Lake Wright Patman in Bowie and Cass counties. Richard Carter (VSC) and Heather White (BAYLU) reviewed preliminary versions of the manuscript.

Collections of *Fagopyrum esculentum* Moench (*Polygonum fagopyrum* L.), buckwheat, were made in May and June of 2003 in the Lyndon B. Johnson National Grasslands near Decatur, Texas (Wise County). This native of Central Asia is reported for Oklahoma, New Mexico, and Louisiana by Kartesz (1999). Despite this proximity, it has not previously been reported for Texas (Correll & Johnston 1970; Stanford 1976; Hatch et al. 1990; Diggs et al. 1999). Since other populations of *F. esculentum* have not been found in North Central Texas, it is unknown if the species is more widely established.

The generic name *Fagopyrum* is derived from Latin "fagus," meaning beech, and "pyros," meaning wheat, because of the resemblance of the plant's seed to the beech-nut. The English name is derived from the German "buchweizen" (Fernald 1950) or a corruption of "boek-weit," the Dutch form of the word "buckwheat" (Grieve 1931).

Fagopyrum esculentum is one of a continuing procession of introduced species (i.e. those originating outside the United States) finding its way into the Texas flora (O'Kennon et al. 1999). Taxa such as *F. esculentum* are variously referred to as "alien," "exotic," or "foreign." In a recent floristic study of North Central Texas (Diggs et al. 1999), it was determined that 17.7% of the flora (394 species) consisted of introduced species.

Lyndon B. Johnson National Grasslands is comprised of numbered "units" scattered throughout much of north central Wise County. *Fagopyrum esculentum* was found in two widely separated units. At the collection site in Unit 71, two populations, approximately 300 meters apart with about twenty individuals at each site, were observed growing along a moist unpaved limestone road, in the roadbed and in the ditch along the road. Plants were young and about 12–18 cm tall. In Unit 3, 18 km west of Unit 71, about 100 plants were

SIDA 20(4): 1717–1720. 2003

FIG. 1. *Fagopyrum esculentum*. Illustration by Jean Henri Jaume St.-Hilaire (1828–1832).

observed in a sandy open woodland. Individuals in this population were as tall as 25 cm.

Fagopyrum esculentum (Fig. 1) can be recognized by the following description (modified from Barkley 1986): annual erect herb, from a slender taproot, to 50 cm tall. Stem glabrous to pubescent at the nodes. Leaves long-petiolate be-

low, becoming sessile above, acuminate, the base broadly sagittate, cordate or truncate; stipules glabrous to puberulent, acute, sheathing but open on one side. Racemes axillary, single or in corybiform to paniculate groups, these 1 per leaf axil, long-pedunculate and usually exceeding the subtending leaf; bracts glabrous, ovate, acute; pedicels not jointed. Perianth white to creamy, streaked tan, 5-lobed, connate below, 3–4 mm long; stamens 8; styles 3, free. Achene strongly exserted, 3-angular, shiny, dark brown. (n = 8, 2n = 16) May–Sep(–Oct). Cultivated fields, disturbed places, waste ground; escaped in many parts of U.S. & the world; Asia. Introduced.

Curiously, the first record of *Fagopyrum* in Texas was found in a plant scrapbook created in 1925. This bound collection of pressed plants, notes, and illustrations was donated to BRIT at some time in the past, but the source is unknown. The plants were collected in Fort Worth, Texas, by M.J. Joyslin. Though a pressed specimen of *F. esculentum* and a fine watercolor of the subject were both preserved on one of the pages, they had been misidentified. As a result of awareness of the new Wise County collections, the scrapbook page was serendipitously recognized as the first, albeit unofficial, collection known from the state.

Voucher specimens: **TEXAS. Wise Co.:** along limestone roadway through Grand Prairie in Unit 71 of the Lyndon B. Johnson National Grasslands, N33° 18' 35", W097° 36' 35", 30 May 2003, *O'Kennon, McLemore, and Neill 18432* (BRIT). **Wise Co.:** sandy open forest of Western Cross Timbers in Unit 3 of the Lyndon B. Johnson National Grasslands, N33° 22' 30", W097° 46' 19", 5 Jun 2003, *O'Kennon and McLemore 18453* (BRIT).

ACKNOWLEDGMENT

Thanks to Guy Nesom of BRIT for assistance in identifying this plant.

Triglochin is a genus of about 20 species, most of these confined to aquatic habitats in the more temperate regions of the world (Thieret 1988). It has not previously been reported for Texas (cf. Haynes & Hellquist 2000; Turner et al. 2003), although at least two species of the genus have been collected in New Mexico (Correll & Correll 1972).

On July 26, 2003 a survey for plants along a saline aquatic habitat near Ruidosa (Presidio County), Texas revealed *Triglochin concinna* var. *debilis* (M.E. Jones) J.T. Howell (Fig. 1) growing along the embankment of a perennial sulfur stream. We have followed the taxonomy of Thorne (1993) in recording this taxon, although we are aware that Haynes and Hellquist (2000) position the latter in their broad concept of *T. maritima* L.

Voucher specimen: U.S.A. **TEXAS. Presidio Co.:** ca 2.2 mi NNW of Ruidosa growing along perennial sulphur streams and about tinajas. *M.W. Turner 99* (SRSC, TEX).

The species was noted to be relatively uncommon at the site, although at least four or five plants were noted along a path of about 40 meters. It was growing with a number of other rarely encountered semiaquatic species of the Trans-Pecos such as *Anemopsis californica*, *Samolus* sp., and *Eustoma exaltatum*.

The sampled site sits upon the property of Mr. James Blumberg of Ruidosa, Texas. We are grateful to him for permitting us entry to his property; indeed, he accompanied us on our impromptu visit, providing helpful comments on this or that collecting site.

ABSTRACT

Andropogon glomeratus (Walt.) B.S.P. var. *glaucopsis* (Elliott) Mohr is reported for Louisiana. A key to separate the Louisiana taxa in the *A. virginicus* complex is provided.

RESUMEN

Se cita *Andropogon glomeratus* (Walt.) B.S.P. var. *glaucopsis* (Elliott) Mohr de Louisiana. Se aporta una clave para separar los taxa del complejo *A. virginicus* en Louisiana.

The *Andropogon virginicus* complex comprises nine closely interrelated species (Campbell 1983). In Louisiana, the complex is represented by four of the nine species: *A. glomeratus* (Walt.) B.S.P., *A. gyrans* Ashe, *A. liebmannii* Hack, and *A. virginicus* L. The taxonomic difficulty of this complex is due to the strong similarity of its members, and the paucity and subtlety of the characters used to separate the taxa (Campbell 1983). A review of the literature reveals a difference of opinion in the recognition of the infraspecific taxa of the *A. virginicus* complex in Louisiana.

Campbell (1983) reported the following taxa as occurring in Louisiana: *Andropogon liebmannii* Hack. var. *pungensis* (Ashe) C.S. Campb., *A. glomeratus* (Walt.) B.S.P. var. *pumilus* (Vasey) Vasey ex L.H. Dewey, *A. gyrans* Ashe var. *gyrans* and var. *stenophyllus* (Hack.) C.S. Campb., and *A. virginicus* L. var. *virginicus* and var. *glaucus* Hack. Thomas and Allen (1993) reported *A. glomeratus* var. *glomeratus*, *A. gyrans* var. *gyrans*, *A. liebmannii* var. *pungensis*, and *A. virginicus* in Louisiana, and listed *A. glomeratus* (Walt.) B.S.P. var. *glaucopsis* (Elliott) Mohr as an undocumented sight record from St. Tammany Parish. Allen (1992) recognized *A. liebmannii*, *A. glomeratus*, *A. gyrans*, and *A. virginicus* as occurring in Louisiana, but did not recognize any infraspecific taxa.

Fieldwork in southeastern Louisiana has resulted in the collection of *Andropogon glomeratus* (Walt.) B.S.P. var. *glaucopsis* (Elliott) Mohr from St. Tammy Parish.

Andropogon glomeratus (Walt.) B.S.P. var. **glaucopsis** (Elliott) Mohr, Bull. Torrey

SIDA 20(4): 1723–1725. 2003

Bot. Club 24:21. 1897. [= *A. glaucus* Muhl., *A. capillipes* Nash, *Cympogon glaucua* Schult.] LOUISIANA. ST. TAMMANY PARISH: N of Bayou Paquet Road, 0.3 mi E of its intersection with Transmitter Road, along fire-line that follows refuge boundary W of dirt road, 26 Oct 2001, *Rosen & Jones 1664* (BRCH-Oregon, NO).

Keys to separate the taxa modified from Campbell (1983) and Allen (1992) follow. See Campbell (1983) for a list of representative specimens from Louisiana. The classification of taxa in the *Andropogon virginicus* complex provided here-with follows that of Campbell (2003).

KEY TO THE LOUISIANA TAXA IN THE *ANDROPOGON VIRGINICUS* COMPLEX

1. Racemes (2–)4–6(–13) terminating each peduncle; sheaths villous _____ **A. liebmannii** var. **pungensis**

1. Racemes 2(–3) terminating each peduncle; sheaths glabrous to villous.
   2. Plants usually less than 1 m tall; leaves usually less than 3 mm wide; raceme sheaths inflated, usually more than 4.6 cm long _____ **A. gyrans**
   2. Plants larger, usually 1 m or more tall; leaves usually more than 3 mm wide; raceme sheaths usually less than 4.6 cm long.
      3. Blades usually more than 37 cm long; stem sheaths often scabrous; ligules usually more than 1 mm long (if less than 1 mm long the keels of the first glume often scabrous below the middle) _____ **A. glomeratus**
      3. Blades usually less than 31 cm long; stem sheaths smooth (rarely somewhat scabrous); ligules less than 1 mm long; keels of the first glume scabrous only above the middle _____ **A. virginicus**

KEY TO THE VARIETIES OF *ANDROPOGON GYRANS* IN LOUISIANA

1. Ligules usually less than 0.8 mm long; plants of well-drained sites _____ **A. gyrans** var. **gyrans**
1. Ligules (0.8–)1.1(–1.5) mm long; plants of wet sites _____ **A. gyrans** var. **stenophyllus**

KEY TO THE VARIETIES OF *ANDROPOGON GLOMERATUS* IN LOUISIANA

1. Leaves and culms conspicuously glaucous _____ **A. glomeratus** var. **glaucopsis**
1. Leaves and culms green.
   2. Keels of first glume scabrous below the middle; plants (0.2–)1.4(–2.5) m tall _____ **A. glomeratus** var. **pumilus**
   2. Keels of first glume scabrous above the middle only; plants (0.6–)1.0(–1.6) m tall _____ **A. glomeratus** var. **glomeratus** (expected in Louisiana)

KEY TO THE VARIETIES OF *ANDROPOGON VIRGINICUS* IN LOUISIANA

1. Leaves and culms conspicuously glaucous _____ **A. virginicus** var. **glaucus**
1. Leaves and culms green _____ **A. virginicus** var. **virginicus**

The range of *Carex conoidea* Schkuhr ex Willd. extends from Newfoundland and Nova Scotia west to Manitoba and south to Missouri, Illinois, Indiana, Ohio, and North Carolina; disjunct and possibly introduced in Arizona (Radford et al. 1964; Mohlenbrock 1999; Yatskievych 1999; Naczi & Bryson 2002). Habitat listed for the species includes "bogs," "low ground, and moist grassy places," "wet meadows, wet prairies," and moist depressions of upland prairies (Radford et al. 1964; Voss 1972; Mohlenbrock 1999; Yatskievych 1999; Naczi & Bryson 2002). The species has not been previously documented from Arkansas (Hyatt 1998; Smith 1988; Arkansas Vascular Flora Committee 2002; Naczi & Bryson 2002).

On 8 May 2003, while conducting a plant survey on Searles Prairie Natural Area in Benton County, Arkansas, we discovered 32 clumps of *Carex conoidea* scattered throughout the western half of the preserve. The species is readily recognized by the combination of light green leaves, scabrous peduncles and culms below the inflorescence, bracts that subtend the uppermost pistillate spikes equaling or exceeding the staminate spike, and its plump, lustrous green perigynia with ca. 20 impressed nerves. *Carex conoidea* can be readily distinguished from other members of the *Carex* section Griseae (L.H. Bailey) Kükenthal in Arkansas by the combination of its scabrous peduncles and culms below the inflorescence, the fewer number of impressed nerves (others in the Section usually have 40 or more nerves), and the position of the staminate spike, well-exserted above the uppermost pistillate spike.

Various authors (e.g., Steyermark 1963; Mohlenbrock 1999; Yatskievych 1999) depict the perigynia of *C. conoidea* as being tapered at both ends. Illustrators undoubtedly only had access to herbarium specimens or over-mature

perigynia, as fresh, mature perigynia of *C. conoidea* are plump and inflated, and watermelon shaped. We have noticed the perigynia of *C. conoidea* shrink and become tapered at both ends upon drying in a plant press.

Clumps of *Carex conoidea* at the Searles Prairie site extend from swales in the prairie to the drier margins of areas just upslope of the depressions. Despite the field characters listed above, identification of *C. conoidea* in the field can be difficult because many of the tufts may have few flowering culms and the culms often lean on or are hidden by adjacent, taller vegetation.

Searles Prairie represents the last intact remnant of the Osage Prairies that once surrounded the town of Rogers, Arkansas in Benton County. It was used as a hay meadow and cut annually until it was donated to the Arkansas Natural Heritage Commission in 1988. Prescribed fire was introduced to the prairie in 1996, with additional prescribed burns in December 2001 and February 2003. Searles Prairie is a low loamy prairie that probably exists because of shallow, impervious clay subsoil and fluctuations in water depth and persistence. This provides graminoids and other ground-covering forbs a competitive advantage over trees (Arkansas Natural Heritage Commission 2002). The Jay and Cherokee silt loam soils are characterized by layers of moderately well-drained silt loam, to somewhat poorly drained silt loam, silty clay loam, and clay. This prairie remains wet for long periods of time after rains due to the clay (United States Department of Agriculture 1977) and poor drainage.

Plants associated with *C. conoidea* at Searles Prairie include *Agrostis hyemalis, Andropogon gerardii, Carex brevior, C. bushii, C. buxbaumii, C. festucacea, Cephalanthus occidentalis, Cicuta maculata, Eleocharis verrucosa, E. wolfii, Eryngium yuccifolium, Eupatorium perfoliatum, Galium obtusum, Juncus spp., Orbexilum pedunculatum, Panicum acuminatum, P. scoparium, Physostegia angustifolia, Potentilla simplex, Pycnanthemum tenuifolium, Ranunculus laxicaulis, Rubus spp*, and *Sisyrinchium angustifolium.*

Voucher Specimens: U.S.A. **ARKANSAS. Benton Co.:** Searles Prairie Natural Area; inter. of U.S. Rt. 62 and Dixieland Rd. in Rogers, AR; T20NR30WS35SE1/4SE1/4SW1/4; Bentonville South 7.5' Quad. 8 May 2003, *McKenzie 2081* (DOV, MO); *Witsell 03-0232* (anhc-Arkansas Natural Heritage Commission, LRU); & 11 Jun 2003 *Witsell 03-0474* (anhc-Arkansas Natural Heritage Commission, APCR, LRU, peh-pers. herb. of Philip E. Hyatt, STAR, UARK).

Carex conoidea is apparently a good indicator of high quality, well-managed prairies in Missouri as well as Searles Prairie in Arkansas (Yatskievych 1999; pers. obs.). The lack of records in some prairies may reflect the lack of survey efforts by individuals familiar with the species' field characters or the difficulty in seeing the diagnostic inflorescences among other prairie vegetation. Searches for the species by the senior author in five prairies in Benton and Pettis counties, Missouri in early June 2002 failed to yield additional populations. Searches in two additional Arkansas prairies by the authors on 9 May 2003 and five

additional sites by Witsell in Arkansas in May and June 2003 failed to document the species at additional localities. Subsequently, however, McKenzie and Smith discovered the species at Hite Prairie in Morgan County and Taberville Prairie in St. Clair County, Missouri on 6 and 7 June, 2003, respectively [*McKenzie 2085* (DOV, MO), *2090* (DOV, MO)]. These collections represent only the third and fourth extant records of this sedge in Missouri. The plants were difficult to see at the two Missouri sites, however, because the 20 and 30 clumps with few flowering culms had inflorescences leaning on or hidden among adjacent, taller vegetation. Despite the limitations mentioned above, future searches for *C. conoidea* should be conducted in other high quality prairies throughout Arkansas and Missouri from about 1 May to 1 June depending on the latitude of the locality to be surveyed.

Botanical nomenclature listed herein follows Yatskievych (1999) or Yatskievych and Turner (1990).

ACKNOWLEDGMENTS

We are grateful to Rob Naczi of Claude E. Phillips Herbarium, Delaware State University, and Philip E. Hyatt, U.S. Forest Service, Atlanta, Georgia for their assistance with this report. Critical reviews by Charles T. Bryson, USDA-ARS Southern Weed Science Research Unit, Stoneville, Mississippi, and an anonymous reviewer improved an earlier draft of this manuscript.

ABSTRACT

An annotated list of 38 additions to the vascular flora of Cleveland County, Arkansas is presented. The additions presented were collected from Moro Bottoms Natural Area, a state-protected old-growth bottomland hardwood forest located in the northwest region of the county.

RESUMEN

Se presenta una lista comentada de 38 adiciones a la flora vascular de Cleveland County, Arkansas. Las adiciones presentadas se recolectaron en Moro Bottoms Natural Area, un bosque pantanoso viejo protegido por el estado, ubicado en la parte noroeste del municipio.

This paper reports 38 additions to the vascular flora of Cleveland County, Arkansas. Collections were taken from windthrow gaps[2] areas within Moro Bottoms Natural Area, a 40 ha old growth bottomland hardwood forest located in the northwestern portion of Cleveland County. The area rests on the floodplain of Moro Creek, a tributary of the Ouachita River, approximately 48 km/30 mi upstream from the mouth of Moro Creek (Peacock 1983). Moro Bottoms supports a diverse stream-bottom community dominated by numerous bottomland oaks (*Quercus spp.*), sweetgum (*Liquidambar styraciflua* L.), bald cypress (*Taxodium distichum* (L.) Richard), and several hickories (*Carya* spp.). The study area and most of Cleveland County reside in the west gulf coastal plain physiographic region of Arkansas. Moro Bottoms is an excellent example of a mature stream-bottom forest becoming old growth through gap regeneration (Devall et al. 2001). The stand contains many old growth features, including little to no

[1]Corresponding author: Danny Skojac, email, dskojac@fs.fed.us.

[2]A severe thunderstorm swept across the Moro Bottoms tract during the summer of 1989, downing trees and creating large openings in the forest canopy commonly referred to as windthrow gaps.

evidence of human-induced disturbance and numerous large diameter trees. Devall et al. (2001) reported cherrybark oak (*Quercus pagoda* Raf.) and sweetgum to have diameters at breast height up to 149 cm/59 in. Additionally, a sample of larger red oaks and white oaks were determined to be approximately 150 years and 250 years of age, respectively (Guldin et al. 1995). Presently Moro Bottoms and adjacent areas are owned and protected by the Arkansas Natural Heritage Commission and the Arkansas Nature Conservancy. The land was purchased from Georgia Pacific Corporation in 1986.

Collecting of specimens was initiated in the spring of 1990 and continued seasonally through the fall of 1992. A more detailed description of sampling methods is discussed in Devall et al. (2001). Collecting efforts and identifications were performed by the authors; some material presented includes collections made by E. Sundell. Specimens are housed in the herbarium collection at the U.S. Forest Service, Southern Hardwoods Laboratory [SHL] (432 Stoneville Road, Stoneville, MS 38776), with some duplicates and voucher material deposited in the University of Arkansas-Monticello Herbarium [UAM]. Smith (1988) and The PLANTS Database (USDA Natural Resources Conservation Service 2002) were consulted to verify the undocumented occurrence of species within Cleveland County we present.

The following annotated list is arranged alphabetically by family, and then by genus and species. Generalized species and habitat descriptions, supplemental to the description of the study area discussed above, cite Radford et al. (1968) and Godfrey and Wooten (1979 and 1981); range data within the state of Arkansas are taken from Smith's (1988) *Atlas*. Collector, number and herbaria of deposit are listed last. Accession numbers are given for those specimens housed in the SHL herbarium.

ARISTOLOCHIACEAE

Aristolochia serpentaria L.—Small herb of bottomland forests and woodland margins; Smith (1988) reports this species for 24 Arkansas counties, mostly in the western haif of the state, it is however listed for neighboring Bradley and Drew counties in southeastern Arkansas; *Sundell* 9136 (UAM).

ASCLEPIADACEAE

Asclepias perennis Walter—A common herb of alluvial forest, usually in low lying areas on heavy clays; reported in Smith (1988) for most eastern counties bordering the Mississippi River and inland into the coastal plain region of the state; present in neighboring Bradley, Dallas, Drew and Lincoln counties; *Devall s.n.* (SHL: 710).

ASTERACEAE

Brickellia eupatorioides (L.) Shinners—Disturbed woodland sites and thickets; a suprising find for Cleveland County, listed by Smith (1988) in western Arkansas counties of quite different physiography than the coastal plain soils of Cleveland County; *Devall s.n.* (SHL: 758).

Eupatorium hyssopifolium L.—A weedy plant of woodland borders and openings, probably seeded in from adjacent upland mixed pine-hardwood stands where it would be more common; only reported by Smith (1988) in four Arkansas counties: Jefferson, Lincoln, Bradley, and Calhoun; *Deval s.n.* (SHL: 738).

Mikania scandens (L.) Willd.—A perennial climbing vine usually associated with disturbed areas and margins of stream-bottom forests,

wet woods; Widespread across southern Arkansas and up the Mississippi River border counties (Smith 1988); *Devall s.n.* (SHL: 718), *Sundell* 9129 (UAM).

CALLITRICHACEAE

Callitriche heterophylla Pursh—Aquatic herb of ditches, shallow depressions, and standing water; widespread, occurring in several Arkansas counties including neighboring Bradley and Drew counties; *Devall s.n.* (SHL:933).

CORNACEAE

Cornus stricta Lam.—Small understory tree of bottomland hardwood forests, usually occurring on heavier textured soils than other dogwoods found in the bottoms; listed in Smith (1988) as *C. foemina*, this species is found in most Arkansas counties, excluding those in the Ozarks, also reported for all counties contiguous to Cleveland County; *Devall s.n.* (SHL: 704, 745).

CRASSULACEAE

Penthorum sedoides L.—Rhizomatous herb common to wet depressional areas, ditches and slough margins, heavy clay soils; widespread, found in several Arkansas counties, including neighboring Drew, Bradley, Calhoun, Dallas, Grant, and Jefferson counties (Smith 1988); *Devall s.n.* (SHL: 703, 711), *Sundell* 9142 (UAM).

EUPHORBIACEAE

Acalypha virginica L.—Weedy annual of disturbed sites and openings, common; found in almost every county in the state (Smith 1988); *Devall s.n.* (SHL: 767).

FABACEAE

Desmodium paniculatum (L.) DC. var. *dillenii* (Darl.) Isley—Woodland margins and openings; Smith (1988) reports this species for several Arkansas counties north and west of Cleveland County, but is reported for neighboring Bradley and Drew counties; *Sundell* 9134 (UAM).

Dioclea multiflora (Torrey & A. Gray) Mohr—Herbaceous vine common in disturbed woodland openings, alluvial forests; reported in 15 Arkansas counties by Smith (1988), mostly in the eastern and southern regions of the state; *Devall s.n.* (SHL: 748), *Sundell* 9140 (UAM).

HYDROPHYLLACEAE

Hydrolea uniflora Raf.—Somewhat decumbent herb of wet ditches, swampy areas, and wet woods; Smith (1988) reports this species for several southern and central Arkansas counties, including neighboring Bradley, Drew, Calhoun, and Jefferson counties; *Devall s.n.* (SHL: 746,747).

HYPERICACEAE

Hypericum walteri J.G. Gmel.—Perennial herb of wet floodplain forests, often associated with cypress swamps and bogs; this species is reported in 15 Arkansas counties, mostly in the southern portion of the state; reported for neighboring Bradley, Dallas, and Jefferson counties (Smith 1988); *Sundell* 9144 (UAM).

LAMIACEAE

Lycopus virginicus L.—Stoloniferous, running herb of bottomland forests, shaded ditchbanks and wet areas; Smith (1988) reports this species in several central counties across the state, as well as neighboring Jefferson, Lincoln, Drew, and Calhoun counties; *Devall s.n.* (SHL: 765).

ONAGRACEAE

Ludwigia palustris (L.) Ell.—Mat forming perennial common to swampy forests, pond margins, and exposed shallow depressions, somewhat invasive; scattered across the state in numerous counties; reported for neighboring Bradley and Drew counties (Smith 1988); *Devall s.n.* (SHL:709).

POLYGONACEAE

Brunnichia cirrhosa Banks ex Gaertn.—Invasive woody vine of woodland openings, margins, and disturbed sites; widespread across the state, with exception to the northwest counties of the Ozarks; Smith (1988) reports this species for all counties contiguous to Cleveland County; *Devall s.n.* (SHL: 754).

RUBIACEAE

Oldenlandia boscii (DC.) Chapm.—Nearly prostrate perennial with linear, opposite leaves; alluvial forests, shallow depressions; very lim-

ited range in Arkansas, only reported for 13 counties in Smith's (1988) *Atlas*, including neighboring Bradley, Drew, and Dallas counties; *Devall s.n.* (SHL: 698).

SAXIFRAGACEAE

Itea virginica L.—Deciduous shrub of bottom land forests, particularly on minor bottom sites away from the Mississippi floodplain forests in the eastern part of the state; widely distributed across the state except in the upland counties of the northwest and those counties bordering the Mississippi River (Smith 1988); *Devall s.n.* (SHL: 755).

SCROPHULARIACEAE

Lindernia dubia (L.) Pennell —Annual herb found along ditch edges and muddy flats border ing waterways, bottomland forests and openings; occurring in almost every county in the state, including neighboring Drew, Bradley, Calhoun, Dallas, and Jefferson coun ties (Smith 1988); *Devall s.n.* (SHL: 735), *Sundell* 9131, 9143 (UAM).

SOLANACEAE

Physalis pubescens L.—Weedy annual found in openings and disturbed sites; Smith's (1988) *Atlas* depicts a sporadic distribution across the state, but comments on its probable occurrence in all Arkansas counties; reported for neighboring Bradley county to the south; *Sundell* 9138 (UAM).

URTICACEAE

Boehmeria cylindrica (L.) Swartz—Very common woodland herb of bottomland hardwood forests, shaded ditches and woodland-edge ecotones; found in nearly every Arkansas county, including neighboring Jefferson, Lin coln, Drew, Bradley, and Dallas counties (Smith 1988); *Devall s.n.* (SHL: 705, 706).

VITACEAE

Vitis cinerea Engelm. ex. Millardet—Common woody vine of disturbed woodland sites and openings; leaves densely pubescent, some what aggressive in habit, restricted mostly to floodplain forest settings; Smith (1988) reports this species in several Arkansas counties across all physiographic regions of the state, including neighboring Jefferson, Lincoln, Drew, Bradley, and Dallas counties; *Devall s.n.* (SHL: 757).

Vitis palmata Vahl—Climbing woody vine with glabrous leaves, common to bottomland forests and disturbed woodland openings; distribution in Arkansas appears limited, re ported by Smith (1988) in 14 counties and for several other counties without vouchered material, mostly in the Mississippi River floodplain, the coastal plain, and Arkansas River valley counties; *Devall s.n.* (SHL: 756).

CYPERACEAE

Carex caroliniana Schwein.—Cespitose perennial of floodplain forests and wet meadows and openings; perigynia somewhat inflated and round, tightly arranged in a compact spike, spikes usually 3; range restricted in Arkansas to 8 central and southern counties with unvouchered reports for several other eastern counties (Smith 1988); *Devall s.n.* (SHL: 751,752).

Carex debilis Michx.—Cespitose sedge of low land woods, seepage areas and wet clearings; pistillate spikes loosely flowered (3-4), perigynia lanceolate tapering gradually to a beak; Smith (1988) reports this species in 13 counties mostly in the coastal plain counties of southern Arkansas including neighboring Grant, Jefferson, Lincoln, Drew, and Bradley counties; *Devall s.n.* (SHL: 729,730,731).

Carex festucacea Schkuhr ex Willd.—Tufted perennial of bottomland hardwood forests and wet openings; little documentation of this species in Arkansas, Smith's (1988) *Atlas* reports only 2 counties where vouchered material has been presented; our record is among the first reports for this species presence in the southeastern region of the state; *Devall s.n.* (SHL: 732).

Carex intumescens Rudge—Tufted perennial of alluvial forests, similar to the rhizomatus *C. louisianica*; pistillate spikes somewhat glo bose, loosely flowered, perigynia inflated gradually tapering to a beak; this species is well distributed across the southern half of the state, Smith (1988) reports this species in neighboring Lincoln, Drew, Bradley, and Dallas counties; *Devall s.n.* (SHL: 713).

Carex reniformis (Bailey) Small—Cespitose perennial common to alluvial forests and wet openings; pistillate spikes many flowered, ovoid, often tightly arranged terminally, perigynia orbicular, relatively flat, conspicuously winged; reported in Smith's (1988) *Atlas* for 10 Arkansas counties mostly in the southern half of the state including neighboring Drew, Bradley, and Calhoun counties; *Devall s.n.* (SHL: 766).

Carex tribuloides Wahlenb.—Abundantly common sedge of bottomland hardwood forests and low lying wet areas; pistillate spikes ovoid to obovoid, tightly arranged terminally, perigynia flat, narrowly ovate, winged apically; reported by Smith (1988) in 18 Arkansas counties mostly in the southern half of the state including neighboring Jefferson, Bradley, and Dallas counties. No doubt this species is present in all coastal plain and alluvial regions of the state; *Devall s.n.* (SHL: 739, 740, 741).

Carex typhina Michx.—Cespitose perennial found in alluvial woodlands; pistillate spikes erect, cylindrical, perigynia ovoid abruptly tapering to a short slender beak; this species is not well documented in Arkansas, reported by Smith (1988) in only 8 counties widely dispersed across the state; *Devall s.n.* (SHL: 762, 763).

JUNCACEAE

Juncus coriaceus Mack.—Clumping, cespitose rush with inflorescence appearing lateral, common to swampy woods and depressions; this rush has a fairly limited range in Arkansas, reported by Smith (1988) in 11 counties all situated within the Ouachita mountains and coastal plain physiographic provinces of the state; *Devall s.n.* (SHL: 708).

POACEAE

Agrostis perennans (Walter) Tuck.—Tufted perennial grass of alluvial forests and wet clearings; Smith (1988) reports this species in several counties dispersed across the state including neighboring Jefferson and Bradley counties; *Sundell* 9126 (UAM).

Cinna arundinacea L.—Rhizomatous perennial grass found in floodplain forests and on wet ditch banks; sporadic distribution across Arkansas, this species is found in 16 counties but with no discernable pattern depicting its range in the state. Smith (1988) reports this species for Bradley County to the south; *Sundell* 9145 (UAM).

Erianthus strictus Baldwin—Robust grass associated with swamp margins and ditches; spikelets conspicuously appressed; reported in Smith's (1988) *Atlas* in several southern Arkansas counties including Drew, Bradley, and Calhoun counties to the south; *Devall s.n.* (SHL: 742).

Leersia lenticularis Michx.—An often decumbent grass with distinctive lenticular florets arranged loosely in an open panicle; this species is associated with bottomland hardwood forests and other shaded swampy settings; appears to be undocumented for several Arkansas counties where it probably exists. Smith (1988) reports this plant in 12 counties mostly in the southern Mississippi River floodplain and coastal plain provinces of the state including neighboring Drew and Bradley counties; *Devall s.n.* (SHL: 749), *Sundell* 9125 (UAM).

Leersia virginica Willd.—Slender, freely branching perennial grass common to alluvial woodlands and swamps; this species is reported by Smith (1988) in several Arkansas counties, primarily in the northern half of the state, but is also documented in a few southern counties as well, including neighboring Drew and Bradley counties; *Sundell* 9124 (UAM).

Panicum dichotomum L.—Tufted perennial grass common to bottomland forests and wet clearings; Smith (1988) reports this plant essentially throughout the state, documented in neighboring Jefferson, Lincoln, Drew, Bradley, Dallas, and Grant counties; no doubt this species is present in Cleveland County; *Devall s.n.* (SHL: 715).

Panicum rigidulum Nees—Abundantly common grass of floodplain forests and wet depressions; this species has a wide distribution, occurring in all physiographic regions of the state, reported in Smith's (1988) *Atlas* for neighboring Jefferson, Lincoln, Drew, Bradley, and Grant counties; *Devall s.n.* (SHL: 770, 771).

ACKNOWLEDGMENTS

The authors wish to thank the Arkansas Natural Heritage Commission and the Arkansas Field Office of the Nature Conservancy for allowing us to collect specimens and conduct research on the preserve. We express our appreciation to those who helped with plant identification, including Eric Sundell, Seth Barnes, Michael Lelong, Allen Moore, and Charles Bryson.

ABSTRACT

Nine species are reported as new to the flora of Arkansas: *Agalinis nuttallii* Shinners (Scrophulariaceae), *Azolla caroliniana* Willd. (Azollaceae), *Crataegus thermopegaea* Palmer (Rosaceae), *Cyrtomium falcatum* (L.f.) K. Presl (Dryopteridaceae), *Nerium oleander* L. (Apocynaceae), *Polygala alba* Nutt. (Polygalaceae), *Punica granatum* L. (Punicaceae), *Ricinus communis* L. (Euphorbiaceae), and *Schinus terebinthifolius* Raddi (Anacardiaceae). They are a mixture of extinct, overlooked, or urban exotic-escaped species, some of which are of special concern as they pose new problems for urban poison control workers. Literature and herbarium work uncovered that 12 Arkansas species previously excluded actually have known and valid vouchers, and they are re-instated: *Acacia farnesiana* (L.) Willd. (Mimosaceae), *Arabis glabra* (L.) Bernh. (Brassicaceae), *Canavalia ensiformis* (L.) DC. (Fabaceae), *Cladium jamaicense* Crantz (Cyperaceae), *Eragrostis trichodes* (Nutt.) Wood (Poaceae), *Halesia diptera* Ellis (Styracaceae), *Lygodesmia juncea* (Pursh) D. Don (Asteraceae), *Prosopis glandulosa* Torr. var. *glandulosa* (Mimosaceae), *Rhynchospora colorata* (L.) Pfeiffer (Cyperaceae), *Rosa canina* L. (Rosaceae), *Sagina procumbens* L. (Caryophyllaceae), and *Trifolium stoloniferum* Muhl. (Fabaceae). Another 13 species previously excluded and/or re-excluded from Arkansas were recently and erroneously re-instated, requiring re exclusion. Another 76 species are here excluded, being reported erroneously as being from Arkansas, based either on literature reports that lack supporting voucher specimens or on a variety of clerical errors. These 21 additions and 89 subtractions to the Arkansas flora point to problems in achieving a uniform basis of deciding which plants to include in a flora and what constitutes sufficient documentation for known and valid vouchers.

RESUMEN

Se citan nueve especies nuevas para la flora de Arkansas: *Agalinis nuttallii* Shinners (Scrophulariaceae), *Azolla caroliniana* Willd. (Azollaceae), *Crataegus thermopegaea* Palmer (Rosaceae), *Cyrtomium falcatum* (L.f.) K. Presl (Dryopteridaceae), *Nerium oleander* L. (Apocynaceae), *Polygala alba* Nutt. (Polygalaceae), *Punica granatum* L. (Punicaceae), *Ricinus communis* L. (Euphorbiaceae), y *Schinus terebinthifolius* Raddi (Anacardiaceae). Son una mezcla de extintas, pasadas por alto, o especies urbanas exóticas-escapadas, alguna de las cuales son de especial interés ya que causan nuevos problemas a los trabajadores del control de venenos urbanos. Con el trabajo bibliográfico y de herbario se descubrió que 12 especies de Arkansas previamente excluidas tienen actualmente testigos conocidos y válidos, y son re-instauradas: *Acacia farnesiana* (L.) Willd. (Mimosaceae), *Arabis glabra* (L.) Bernh. (Brassicaceae), *Canavalia ensiformis* (L.) DC. (Fabaceae), *Cladium jamaicense* Crantz (Cyperaceae), *Eragrostis trichodes* (Nutt.) Wood (Poaceae), *Halesia diptera* Ellis (Styracaceae), *Lygodesmia juncea* (Pursh) D. Don (Asteraceae), *Prosopis glandulosa* Torr. var. *glandulosa* (Mimosaceae), *Rhynchospora colorata* (L.) Pfeiffer (Cyperaceae), *Rosa canina* L. (Rosaceae), *Sagina procumbens* L. (Caryophyllaceae), y *Trifolium stoloniferum* Muhl. (Fabaceae). Otras 13 especies excluidas previamente y/o re-excluidas

SIDA 20(4): 1737–1757. 2003

de Arkansas fueron reciente y erróneamente re-instauradas, y necesitan una re-exclusión. Otras 76 especies se excluyen aquí, por haberse citado erróneamente de Arkansas, basadas tanto en citas bibliográficas que carecen de pliegos testigo o en varios errores administrativos. Estas 21 adiciones y 89 substracciones a la flora de Arkansas apuntan los problemas de poner a punto una base uniforme para decidir que plantas incluir en una flora, y que constituye suficiente documentación para los pliegos testigo conocidos y válidos.

The preparation of a state flora remains the grandest state scientific enterprise in most states. More than 1200 articles by nearly 100 botanists documented and explained the diversity, abundance, and distribution of its flora and vegetation (Peck & Peck 1988; Peck et al. 2000). Vascular plant floristics in Arkansas commenced with the 1819 exploratory travels, collections, and published list by Thomas Nuttall (1835). Earlier expeditions commented on plants, but appeared to either not have vouchers or none have survived from Arkansas locations (Palmer 1927, Morton 1967, MacRoberts et al. 1997). Subsequent flora lists were prepared by Lesquereux (1860) of 1320 species and by Branner and Coville (1891) of 1534 species, but were developed from limited field work and were poorly supported with extant vouchers. Buchholz and Palmer (1926) attempted to verify, locate vouchers, or re-collect many old Arkansas records, and in the process, added 534 species for a total of 2068. Demaree (1943) compiled all past lists, personally added 694 species, and presented a total list of 2723 species. As stated by Demaree (1943), many species on his list were not his records, but were compiled at face value from prior lists. Demaree (1943) knew some were of dubious identity, probably lacked vouchers, and contained records from Oklahoma when it was part of the "Arkansas Territory" from 1819–1836. But there was a war going on, no resources could be spared to validate the list, and the fate of species-level biology in Arkansas was in doubt.

Edwin B. Smith inherited the Arkansas state flora enterprise. Through near heroic efforts, being the last to attempt a "one man band" approach to a state flora, he produced two annotated checklists with county maps. Smith (1978) provided an annotated checklist with county dot maps for 2338 species, a list of 200 possible additions, a list of 365 excluded species (many old reports appeared to lack vouchers of any kind), and state maps with 40,941 county dots. Smith (1988) presented a revised list and maps for 2469 species, 324 possible additions, 375 excluded species, and maps with 49,510 county dots.

In 1998, a consortium of 16 botanists formed the Arkansas Vascular Flora Committee to prepare a checklist, database, atlas, and manual. To date, the Arkansas Vascular Flora Committee has located and verified vouchers for over 3350 taxa. Based upon the immensely helpful national electronic lists (Kartesz 1998, Kartesz & Meacham 1999; NRCS 1999), near monographic state floras from adjacent Missouri and Texas, the atlas and manual of the Flora of the Great Plains, checklists and atlases of Louisiana, Tennessee, and Texas, and the serial

volumes of the Flora North America project (Flora North American Editorial Committee 1993+), another 80 taxa might yet be added.

Through herbarium search and review of literature and national electronic floras, 110 noteworthy Arkansas species were identified that required addition (9), reinstatement (12), re-exclusion (13), or exclusion (76). The nine additions included overlooked but long-standing elements of the Arkansas flora and recent escapes with properties of ecological concern (invasive) or human concern (toxic). Twelve re-instated species included previously excluded, extinct, or extirpated species that required re-instatement as their vouchers were finally located, were replaced, or were erroneously excluded [criteria and judgment differs with differing workers]. Thirteen species were re-excluded that were erroneously reported and re-reported as present in Arkansas. Another 76 species were excluded as they lack a valid or known voucher to support their inclusion. With this update, the listed flora of Arkansas is treated more consistently with that of floras of other states in the region and with national lists.

The purpose of this current report, beyond communication of state and county noteworthy records, was to demonstrate the need for continued judgment and interpretation of floristic information, whether in the older hard-copy literature or in the newer data-based, on-line records. Records of each state need to be reviewed by experts in taxonomic groups as well as local experts to insure a correct name and proper documentation exists. Criteria for inclusion need to be carefully followed regarding invasive, escaped, waif, and naturalized plants. Equally important is to exclude species erroneously included in past lists. There may well be more exclusions than new additions (Ertter 2000). Documentation of known and valid vouchers as to herbarium of deposit, identity, collector, and number should be the basis for inclusion, not just a passage in the text, or a tone-map or dot-map. Literature errors may need to be removed more than once from the database. Increased efforts at quality control and assurance through time and effort will result in a continually improved and more powerful tool at both the state and national levels (Kartesz 2000).

ADDITIONS TO ARKANSAS FLORA

Agalinis nuttallii Shinners (Scrophulariaceae)—This is the "first report" for Arkansas of this historical plant, now considered extinct. First collected and named by Nuttall based on his work in Arkansas (Nuttall 1835, Palmer 1927) as *Gerardia longifolia* Nutt. Although similar to *G. holamantha* (Pennell) Pennell, Pennell (1935) asserted that it was distinct. The lack of conservation of the name *Gerardia* required a new combination that was made by Shinners (1962) in honor of its first collector. The species was listed for Arkansas by Lesquereux (1860). Surprisingly, the species was not listed, discussed, or excluded by Smith (1978, 1988), but was listed as an Arkansas endemic by Kartesz and Meacham (1999).

Voucher: **ARKANSAS:** along the bank of the Arkansas, locality not specified, *Nuttall s.n.* (BM, K, PH).

Azolla caroliniana Willd. (Azollaceae)—The first collection of this species from Arkansas was from a swamp at Spruell's Recreation Area, 2 mi north of Doddridge along US 71 on 19 May 1977 by B.L. Lipscomb. All other material of this genus from Arkansas was referable to *A. mexicana* Schlecht. & Cahm. ex K. Presl.

Voucher: **ARKANSAS: Miller Co.:** *Lipscomb 2064* (LRU).

Crataegus thermopegaea Palmer (Rosaceae)—This species is reported based on a collection by E.J. Palmer at Hot Springs, Arkansas in Apr and Oct 1925. It was described as a new species by Palmer (1926). Palmer described 67 species as new for *Cratageus*; this is the only one still recognized on national lists. The species was not recognized by Tucker (1976) or Smith (1978, 1988), but was recognized as an Arkansas endemic by Kartesz and Meacham (1999).

Vouchers: **ARKANSAS: Garland Co.:** *Palmer 26843* (A), *Palmer 26843* (G).

Cyrtomium falcatum (L.f.) K. Presl (Dryopteridaceae)—This is an escaped exotic species that can persist several years in Arkansas when its rhizome is well protected; plants remain wintergreen in southern to central Arkansas. The species is cultivated state-wide, escaping rarely, but persisting in urban waste areas, at least in Little Rock. A related species *Cyrtomium fortuneii* J. Sm. (Fortune's Net-vein Holly Fern) was collected in 1988 by Wilson Baker as part of a contract with The Nature Conservancy to study plants in the batture lands of Desha Co., Arkansas. Unfortunately, the voucher material was taken to Tall Timbers Research Station, Georgia, and remains unmounted and unreported. Therefore, the later collection from Little Rock was the first report of the genus from Arkansas.

Voucher: **ARKANSAS: Pulaski Co.:** *Peck 02744* (LRU).

Nerium oleander L. (Apocynaceae)—This is a very toxic horticultural shrub, escaping from landscapes to urban waste places in Boyle Park, Little Rock, evidently at least "root-hardy" and persisting in Arkansas.

Voucher: **ARKANSAS: Pulaski Co.:** *Peck 02-845* (LRU).

Polygala alba Nutt. (Polygalaceae)—This species was first collected in Arkansas on 21 May 1977 from a wooded hillside 12 mi north of Murfreesboro in Pike Co. by B.L. Lipscomb.

Voucher: **ARKANSAS: Pike Co.:** *Lipscomb 2177* (LRU).

Punica granatum L. (Punicaceae)—This horticultural shrub has persisted at old homesteads in Arkansas and has escaped to urban waste places and to Boyle Park, Little Rock, where it has persisted for decades.

Vouchers: **ARKANSAS: Little River Co.:** *Tucker 16121* (APCR), **Pulaski Co.:** *Luyet 8311* (LRU).

Ricinus communis L. (Euphorbiaceae)—A very toxic horticultural, suffrutescent plant or semi-perennial herb, escaping from cultivation and establishing small colonies in urban and rural waste or disturbed areas, now state-wide in Arkansas.

Vouchers: **ARKANSAS: Bradley Co.:** *Leslie 1515* (UAM). **Pulaski Co.:** *Luyet 137* (LRU). **Stone Co.:** *Leonard 124* (LRU), and by the author and deposited at LRU in 22 counties: **Arkansas Co.:** *02369*, **Baxter Co.:** *98117*, **Cleburne Co.:** *96185*, **Faulkner Co.:** *97321*, **Garland Co.:** *97268*, **Grant Co.:** *99244*, **Hot Spring Co.:** *97232*, **Independence Co.:** *96344*, **Izard Co.:** *96127*, **Jackson Co.:** *99176*, **Jefferson Co.:** *02376*, **Lonoke Co.:** *02276*, **Marion Co.:** *96432*, **Monroe Co.:** *96518*, **Phillips Co.:** *02333*, **Prairie Co.:** *02312*, **Saline Co.:** *02350*, **Searcy Co.:** *98253*, **Van Buren Co.:** *98278*, **White Co.:** *99561*, **Woodruff Co.:** *97566*, and **Yell Co.:** *02467*.

Schinus terebinthifolius Raddi (Anacardiaceae)—A toxic, invasive woody shrub-tree, was introduced into a backyard in Camden in southern Arkansas as a horticultural novelty. The tree with plentiful red berries was a Christmas tree "present" from Florida. It was planted and had survived 3 winters, with root suckers and seedlings produced around the original stock. The plants were eradicated by the homeowner upon advice of the author before it became further established or irreparably naturalized.

Voucher: **ARKANSAS: Ouachita Co.:** *Peck 90117* (LRU).

REINSTATEMENTS TO ARKANSAS FLORA

Acacia farnesiana (L.) Willd. (Mimosaceae)—This species was first reported for Arkansas by Demaree (1943). Tucker (1976) included this species, but considered it to be a "rare adventive." Smith (1978, 1988) excluded it from the state flora, as the specimen was sterile material [not unusual for woody plant collections], and he questioned the correctness of its identity. The voucher specimens are of this species, collected from a 3–4 m tall tree adjacent to the Arkansas River near Little Rock, but no longer present.

Voucher: **ARKANSAS: Pulaski Co.:** *Palmer 29600* (A, UARK).

Arabis glabra (L.) Bernh. (Brassicaceae)—This species was first reported for Arkansas by Branner and Coville (1891), compiled by Demaree (1943), and reported by Fernald (1950). Smith (1978) suggested that this record might be a misidentified *Arabis laevigata* (Muhl. ex Willd.) Poir., but he did not consult the voucher. Al-Shehbaz (1988) noted that M. Hopkins (1937) reported this species from Pulaski Co., AR. Smith (1988) excluded it again, but noted that "as it has not been recollected in the last 50 years [1895], I assume it is no longer extant in the state."

Voucher: **ARKANSAS: Pulaski Co.:** *Hasse s.n.* (NY).

Canavalia ensiformis (L.) DC. (Fabaceae)—Sauer (1964) reported this prehistoric American Indian domesticate for Arkansas based on a collection by Harvey in

1885 and by Jennings in 1938. All other specimens, particularly at UARK, are based on cultivated materials dating from 1930 to1959. The species was listed for Arkansas by Kartesz and Meacham (1999), citing Sauer (1964).

Vouchers: **ARKANSAS:** locality not specified, *Harvey s.n.* (GH), *Jennings s.n.* (F).

Cladium jamaicense Crantz (Cyperaceae)—The species was reported first by Branner and Coville(1891). Demaree (1943) reported this species based on that report and on his 1939 collection in Bradley Co., AR (*Demaree 19433* BRIT, MO). Without examining the vouchers, Smith (1978) listed it as "excluded" from Arkansas, based on its reported range in the floras of Texas and the Carolinas. Orzell and Bridges (1987) examined and verified the Demaree collections, but considered it to be probably extirpated from the state. Smith (1988) listed it as "excluded" in that it was only a waif and now extirpated from Arkansas. The species was recently collected in four Arkansas counties.

Vouchers: **ARKANSAS: Bradley Co.:** *Peck 98247* (LRU). **Calhoun Co.:** *Peck 20220* (LRU). **Ouachita Co.:** *Peck 20240* (LRU). **Union Co.:** *Peck 20234* (LRU).

Eragrostis trichodes (Nutt.) Wood (Poaceae)—The species was reported from Arkansas by Moore (1961) from two counties (Logan and Pulaski), listed by Gould (1975) from southwestern Arkansas, but excluded from the flora by Smith (1988), as one specimen (*Moore 470609* UAM) was a misidentified sheet of *E. hirsuta*. The 2nd specimen cited by Moore (1961) from Pulaski Co. is not at UARK. Kartesz and Meacham (1999) listed this species as present in Arkansas citing a Nuttall voucher at PH.

Voucher: **ARKANSAS:** without precise locality data, *Nuttall s.n.* (PH); **Pulaski Co.:** *Merrill 14* (UARK?).

Halesia diptera Ellis (Styracaceae)—The species was first reported for Arkansas by Branner and Coville (1891), compiled by Demaree (1943), and reported by Tucker (1976). Reveal and Seldin (1976) reviewed the taxonomy of this species and its varieties. Smith (1978) included this species in his first checklist, but he excluded it from the second edition (Smith, 1988), noting that it was collected only once in 1887 by Letterman, that "it has not been re-collected in the last century, [and] it is probably no longer extant in the state." R. G. Erickson (1989) discovered a second population in Lafayette Co., Arkansas. The specimen was sent to APCR, but was apparently lost before being mounted. More recently, a third population was located in Union Co. by R. Dale Thomas.

Vouchers: **ARKANSAS: Nevada Co.:** *Letterman s.n.* (ILL), **Union Co.:** *Thomas 109,060* (NLU).

Lygodesmia juncea (Pursh) D. Don (Asteraceae)—This species was first reported for Arkansas by Buchholz and Palmer (1926). The first vouchered collection was by Demaree (1943). Vuilleumier (1973) reported this species for Arkansas based on Demaree's 1937 collections. Tomb (1980) re-reported the species from Arkansas,

noting the locality as Magnet Cove, AR. Without examining vouchers or seeing the plant in the field, Smith (1978, 1988) excluded this species as being "only a waif," and therefore not part of the "normal Arkansas flora." Orzell and Bridges (1987) reported the status of this species in Arkansas as being "probably extirpated." Kartesz and Meacham (1999) reported this species as present in Arkansas, but cited Smith (1988).

Vouchers: **ARKANSAS: Hot Spring Co.:** *Demaree 16264* (BRIT, NY).

Prosopis glandulosa Torr. var. **glandulosa** (Mimosaceae)—Tucker (1976) reported this species based on collections by D. M. Moore in 1954 and 1955 in Pulaski Co., noting that it was a "rare adventive" of potentially long duration that was collected along the railroad tracks on the southern edge of Little Rock, apparently brought in with livestock. Smith (1978, 1988) excluded this species, considering it to be only a waif, and not "part of the normal flora."

Vouchers: **ARKANSAS: Pulaski Co.:** *Moore 54343, 55517* (UARK).

Rhynchospora colorata (L.) Pfeiffer (Cyperaceae)—First reported for Arkansas by Demaree (1943) based on his collections at Warren Prairie, Bradley Co., Arkansas. Smith (1978) listed this species for Bradley Co. and noted a potential report from Pope Co., Arkansas. Orzell and Bridges (1987) reported "a stand of thousands of plants from Little River County," but opined that the Bradley Co. population was extirpated. Smith (1988) reported this species for Bradley Co. and Little River Co., but noted that the Pope Co. record was erroneous, based on diseased material of a *Cyperus* sedge. Similarly diseased sedge plants occur in Bradley Co. Recently, the species was collected in another 10 counties.

Vouchers: **ARKANSAS: Ashley Co.:** *Sontag 76* (LRU). **Bradley Co.:** *Demaree 15044* (F, MO, BRIT, NY); *Demaree 19264* (GH, MO, NY, BRIT, UARK); *Demaree 19268* (BRIT); *Demaree 19269* (MICH, NLU, NY, TEX, UARK); *Logan 101* (UCAC). **Calhoun Co.:** *Marian 22* (LRU). **Columbia Co.:** *Smith 32* (LRU). **Drew Co.:** *Smith 32* (LRU). **Hempstead Co.:** *Sontag 108* (LRU). **Lafayette Co.:** *Smith 76* (LRU). **Little River Co.:** *Orzell 2726* (APCR, MO, NLU, BRIT, TEX, UARK). **Miller Co.:** *Sontag 63* (LRU). **Ouachita Co.:** *Bell 99* (LRU). **Union Co.:** *Peck 20235* (LRU).

Rosa canina L. (Rosaceae)—Smith (1978, 1988) excluded this species, based on a Franklin Co. collection, as it "probably represents a local escape or was persistent at an old home site; it should not be considered as a normal part of our flora." Yet, many species have entered the Arkansas flora by this method of introduction. Kartesz and Meacham (1999) listed it as "present," based on Smith (1988).

Voucher: **ARKANSAS: Franklin Co.:** *Davis 449* (UARK)

Sagina procumbens L. (Caryophyllaceae)—First reported by Branner and Coville (1891), and then listed by Demaree (1943). Without inspecting vouchers, Smith

(1978) excluded this species, suggesting that it was a misidentified *S. decumbens* (Ell.) Torr. and A. Gray. Crow (1978) noted that it was correctly named and was collected in Pulaski Co. in May 1886. Smith (1988) re-excluded this species, noting that it was "not re-collected in the intervening century."

Voucher: **ARKANSAS: Pulaski Co.:** *Hasse s.n.* (MONTU).

Trifolium stoloniferum Muhl. (Fabaceae)—Smith (1978) did not list this species, but noted it as a "possible addition" to the flora of Arkansas. Brooks (1983a, 1983b; Batgie, 1985) reported that it had been collected from Arkansas in 1896. Smith (1988) excluded it from the flora of Arkansas as it was "no longer extant—and I am therefore excluding it." This species has declined across its entire range since settlement.

Voucher: **ARKANSAS: Independence Co.:** *Eggert s.n.* (MO).

RE-EXCLUDED FROM ARKANSAS FLORA

Asclepias sullivantii Engelm. ex A. Gray (Asclepiadaceae)—First reported in Arkansas by Buchholz and Palmer (1926). This report was based on a collection from the southwestern corner of the University of Arkansas campus at Fayetteville, Washington Co. According to the card file by D. Moore kept at UARK, E.J. Palmer observed it on 12 Jun 1923, and it was collected by Buchholz on 13 Jun 1923 (*Buchholz 20145-6*). The voucher is not at UARK or MO, but it might be at the Arnold Arboretum. A second report was made erroneously by Smith (1978, 1988) from Jackson Co., Arkansas, based on a misidentified collection by D. Moore (*Moore 440164* UARK). Another specimen of this species was collected by E.J. Palmer from Jackson Co., Missouri, deposited at MO, and reported by Woodson (1954). Woodson (1954) did not map this species in Arkansas. The Palmer specimen label was typed on a "Flora of Arkansas" label, with the corrected state name of Missouri hand written above the crossed-out "Arkansas."

Asplenium ruta-muraria L. (Aspleniaceae)—Reported by Nuttall (1835) and uncritically re-reported a dozen times from Arkansas for more than 165 years, but a voucher specimen has never been located at BM, K, P, or in any Arkansas herbarium. This species was excluded many times from the flora of Arkansas (Smith 1978, Taylor 1984, Smith 1988, Peck and Taylor 1995). Kartesz and Meacham (1999) erroneously listed the species as present in Arkansas citing Smith (1988).

Burmannia biflora L. (Burmanniaceae)—Reported by Demaree (1943, p. 21) as his record, but without any comment. The species was not listed nor excluded by Smith (1978, 1988). A specimen from Cass Co., Texas, adjacent to Texarkana, Miller Co., Arkansas, exists at BRIT (per. comm., G. Diggs). The species occurs nearby in Louisiana as well.

Dryopteris ×neowherryi W.H. Wagner [*D. goldiana* × *marginalis*] (Dryopterida-

ceae)—Montgomery (1981) erroneously reported this hybrid from Arkansas in a summary of *Dryopteris* hybrid morphology, systematics, and phytogeography. Montgomery confused this hybrid with *D.* ×*leedsii* which does occur in Arkansas. Peck and Taylor (1995) and Peck (2000) specifically excluded this hybrid from Arkansas. Kartesz and Meacham (1999) erroneously listed this species as present in Arkansas citing Montgomery (1981).

Escobaria missouriense (Sweet) D.R. Hunt var. **similis** (Englem.) N.P. Taylor (Cactaceae)—Benson (1982) reported *Coryphantha missouriense* (Sweet) Britton and Rose var. *caespitosa* (Engelmann) Benson from Miller Co., AR, based on a specimen with only an indeterminent location of "Arkansas" [*Dyck s.n.*, 1857 (MO)]. Zimmerman (1985) referred to this taxa as *C. missouriensis* (Sweet) Britton and Rose var. *similis* (Englemann) A. Zimmerman and mapped it in Texas and Oklahoma, but not in Arkansas. Orzell and Bridges (1987) excluded this find by Benson (1982), considering it to be a Oklahoma record based on confusion over the concept of Arkansas Territory. The "Arkansas Territory" (1819 - 1836) also included what is modern Oklahoma. Smith(1988) agreed and cited Orzell and Bridges (1987). However, to accept this interpretation, one must assume that Arkansas had been a state for 21 years at the time the specimen was collected and that the collector did not know this. Kartesz and Meacham (1999) erroneously listed the species as present in Arkansas, but cited Smith (1988) who excluded it.

Huperzia ×**bartleyi** (Cusick) Kartesz & Gandhi [*H. lucidula* × *porophila*] (Lycopodiaceae)—Smith (1988) reported this as a "possible addition" to the flora of Arkansas, meaning that it might be found in the state in the indefinite future, but that it had not as of yet been so documented. Peck and Taylor (1995) specifically excluded this hybrid from the flora of Arkansas, noting that only *H. lucida* Michx. was known in Arkansas. Kartesz and Meacham (1999) erroneously listed this hybrid for Arkansas citing Smith (1988).

Krameria lanceolata Torr. (Krameriaceae)—This species was reported from Arkansas by Nuttall (1835), listed by Lesquereux (1860), and again by Branner and Coville (1891). Demaree (1943) compiled the name into his list, but a voucher has not been located. Smith (1978, 1988) excluded this species. Kartesz and Meacham (1999) erroneously listed the species as present in Arkansas, citing Demaree (1943). The origin of this record may be a Nuttall specimen from Oklahoma. Alternatively, there is a specimen collected in 1836 [*C.W. Short s.n.* MO] at the "Arkansas [River] at Leavenworth," a location within the Arkansas Territory, but now in present-day Oklahoma.

Lesquerella angustifolia (Torr. & A. Gray) Wats. (Brassicaceae)—This species was collected by Nuttall (1835) from "prairies near the Red River, Arkansas." Re-reported by Branner and Coville (1891), Small (1913), and listed by Demaree (1943). The collection location was actually in McCurtain Co., Oklahoma, then part of Arkansas Territory (Goodman, 1966). Rollins and Shaw (1973) excluded it. Smith

(1978) listed this species as a "possible addition" to the state flora. Smith (1988) excluded this species as it was never documented from present day Arkansas. The species was erroneously re-listed for Arkansas on some national e-lists.

Lesquerella gracilis (Hook.) Wats. var. **repanda** (Nutt.) Pays. (Brassicaceae)—This species was collected by Nuttall (1835) from "prairies near the Red River, Arkansas." Re-reported by Branner and Coville (1891), Small (1913), and listed by Demaree (1943). The location was actually in McCurtain Co., Oklahoma, then part of Arkansas Territory (Goodman, 1966). Rollins and Shaw (1973) and Smith (1978, 1988) excluded this species from the flora of Arkansas. This species was erroneously re-listed for Arkansas on some national e-lists.

Lonicera albiflora Torr. & A. Gray (Caprifoliaceae)—This species was reported from Arkansas by Small (1913). Ferguson (1966a) noted that the type locality was "Fort Towson, Arkansas." Fort Towson is in SE Oklahoma, another confusion regarding Arkansas Territory which included present day Oklahoma. This species was excluded by Smith (1978, 1988). Kartesz and Meacham (1999) erroneously re-listed the species as present in Arkansas, citing Smith (1988).

Rhynchosia minima (L.) DC. (Fabaceae)—This species was reported for Arkansas by Greer (1978) based on a specimen collected in the "Arkansas Refuge [White River?]," ostensibly in Phillips or Arkansas counties, but with a dot that was placed in Desha Co. The specimen (*Cory 45847* FSU) was actually from Aransas Co., Texas, Aransas National Wildlife Refuge. Smith (1988) excluded this species from Arkansas. Kartesz and Meacham (1999) erroneously re-listed this species as present in Arkansas, citing Smith (1988).

Rivina humilus L. (Phytolaccaceae)—This species was collected by Nuttall at "Red River, Arkansas" (voucher at NY), in present day Oklahoma, then Arkansas Territory. The species was reported by Branner and Coville (1891). Demaree (1943), who had never seen it in Arkansas, commented that this species must be "probably rare in the state." Smith (1978, 1988) did not list this species, and he only considered it as a "possible addition." Kartesz and Meacham (1999) erroneously re-listed the species as present in Arkansas, citing Smith (1988). Some confusion may have resulted from uncorrected specimen labels on duplicates, such as an E.J. Palmer specimen at MO (*E.J. Palmer #30521*), collected on 7 June 1926 from Brewster Co., Texas, typed on a "Flora of Arkansas" label blank with the correct state typed above the strike-over of "Arkansas."

Smilax auriculata Walt. (Smilacaceae)—This species was reported for Arkansas by Duncan (1967). Tucker (1976) noted it was an enigmatic, 500 mi range extension reported by Duncan (1967), but a voucher was not located. Smith (1978, 1988) mapped it in his Arkansas atlas without seeing a voucher, referring to Duncan (1967). Smith (1994) listed the species as a "possible addition" denoted by an asterisk. Kartesz and Meacham (1999) erroneously listed the species as present in Arkansas, citing Smith (1988). No Arkansas specimen vouchered this record; it was mismapped by Duncan (1967). Moore (1941) reported that *S.*

walteri was present in Arkansas near Hot Springs, Garland Co. It was also known from Hempstead Co. at this time (*Buchholz 395* UARK). Coker (1944) re-reported the presence of *S. walteri* in "swamps," in Garland Co., Arkansas. The dot for Garland Co. that belonged on the *S. walteri* map, was absent in Duncan (1967). A clerical error was made: the dot for *S. walteri* was incorrectly mapped onto the *S. auriculata* map and placed incorrectly in the adjacent Montgomery Co.

EXCLUSIONS FROM ARKANSAS FLORA

Agrostis capillaris L. (Poaceae)—The species was listed by Moore (1961); Smith (1988) noted the species as a "possible addition," citing that all earlier records were based on cultivated material (turf), not on escaped or established plants beyond cultivation; Kartesz and Meacham (1999) erroneously listed the species as "present," citing Smith (1988).

Arundinaria gigantea (Walt.) Muhl. subsp. **tecta** (Walt.) McClure (Poaceae)—Branner and Coville (1891) listed this variety for Arkansas without citing a voucher. Efforts since Buchholz and Palmer (1926) have failed to locate a known and valid voucher. Kartesz and Meacham (1999) listed this variety for Arkansas, citing the compiled list of Demaree (1943).

Asclepias rubra L. (Asclepidaceae)—This species was listed by Kartesz and Meacham (1999) for Arkansas, based on one of a series of unpublished manuscripts (A. Radford et al., eds. Vascular Flora of Southeastern United States). The species occurs to the south in Louisiana and eastward along the Gulf Coastal Plain (Woodson 1954), but a voucher from Arkansas has not been located.

Boltonia diffusa E.L. var. **diffusa** (Asteraceae)—Branner and Coville (1891) listed this variety for Arkansas without citing a voucher. Efforts since Buchholz and Palmer (1926) have failed to locate a known and valid voucher. Kartesz and Meacham (1999) listed this variety for Arkansas, citing the compiled list of Demaree (1943).

Buddleyja lindleyana Fortune ex Lindl. (Buddlejaceae)—Kartesz and Meacham (1999) listed this species as present in Arkansas and cited a reference to one of a series of unpublished manuscripts (A. Radford et al., eds. Vascular Flora of the Southeastern United States). Although known as a horticultural shrub planted across the state, it has not been reported to escape in Arkansas.

Carex debilis Mich. var. **rudgei** Bailey (Cyperaceae)—This variety was listed for Arkansas by Buchholz and Palmer (1926), compiled by Demaree (1943), tracked as *C. debilis* Michx. var. *pubens* Gray by Arkansas Natural Heritage Commission, reduced to synonymy by Smith (1988), and reinstated as present by Kartesz and Meacham (1999) citing ANHC. In Vol. 23 of Flora North America, the two varieties are considered to be a synonym of var. pubens, already known from Arkansas.

Carex microrhyncha Mack. (Cyperaceae)—Kartesz and Meacham (1999) listed this species for Arkansas based on a personal communication with S. D. Jones; Vol. 23 of Flora North America reduced it to a synonym of *C. umbellata* Schkuhr ex Willd., already known from Arkansas.

Carex tenera Dewey (Cyperaceae)—The species was listed by Smith (1968) as not present in Arkansas, but he considered it to be a "possible addition"; listed erroneously as "rare" for Arkansas by Kartesz and Meacham (1999) citing Smith (1988).

Carex verrucosa Muhl. (Cyperaceae)—This species was listed by Demaree (1943). It was reported by Smith (1968) as a "possible addition," as it lacked a known voucher. It was reinstated erroneously by Kartesz and Meacham (1999) as "present, but now extinct."

Chenopodium berlandieri Moq. var. **boscianum** (Moq.) H. A. Wahl (Chenopodiaceae)—Branner and Coville (1891) listed this variety for Arkansas without citing a voucher. Efforts since Buchholz and Palmer (1926) have failed to locate a known and

valid voucher. Kartesz and Meacham (1999) listed this variety for Arkansas, citing the compiled list of Demaree (1943).

Chloris cucullata Bisch. (Poaceae)—This species was listed by Branner and Coville (1891), compiled by Demaree (1943), excluded by Smith (1988), and erroneously re-listed as "?present" in Arkansas by Kartesz and Meacham (1999) citing Smith (1988).

Clinopodium vulgare L. (Lamiaceae)—This species was listed for Arkansas as *Satureja vulgaris* (L.) Fritsch. by Branner and Coville (1891), compiled by Demaree (1943), and erroneously re-listed by Kartesz and Meacham (1999). It is likely that this record was based upon mis-identified *Satureja arkansanum* (Nutt.) House. rather than upon a garden escape, but a voucher is lacking to confirm this.

Collinsonia canadensis L. (Lamiaceae)—This species was reported by Demaree (1943) and excluded by Smith (1968) as the record lacked known voucher. The species was erroneously re-instated by Kartesz and Meacham (1999), but they cited Smith (1988).

Corispermum americanum (Nutt.) Nutt. var. **americanum** (Chenopodiaceae)—This variety was not listed by Smith (1988). Kartesz and Meacham (1999) listed this variety for Arkansas and cited Smith (1988). Kartesz and Meacham (1999) did not list as present in Arkansas the related *C. americanum* (Nutt.) Nutt. var. *rydbergii* Mosyakin, which Smith (1988) documented in Arkansas under *C. hyssopifolium* L. Perhaps the compiler added the wrong variety and deleted the correct variety of this species for Arkansas.

Crataegus monogyna Jacq. (Rosaceae)—This exotic and horticultural species was listed without a voucher by Tucker (1976), based on the expert authority and memory of E.J. Palmer. Palmer visited UARK in 1955 to annotate specimens and left a hand-written list of *Crataegus* from Arkansas based in part on his memory. Smith (1978, 1988) listed it only as "possible" for Arkansas, citing Tucker (1976). Kartesz and Meacham (1999) erroneously re-listed it for Arkansas and cited Smith (1988). The list was not extant at UARK.

Crataegus succulenta Schrad. ex Link (Rosaceae)—This exotic and horticultural species was listed by Tucker (1976), based on the expert authority and memory of E.J. Palmer. Palmer visited UARK in 1955 to annotate specimens and left a hand-written list of *Crataegus* from Arkansas based in part on his memory. Smith (1978, 1988) listed it only as "possible" for Arkansas, citing Tucker (1976). Kartesz and Meacham (1999) erroneously listed it for Arkansas and cited Smith (1988). The list was not extant at UARK.

Crinum americanum L. (Liliaceae)—This species was listed by Branner and Coville (1891), compiled by Demaree (1943), excluded by Smith (1988), and reinstated as "present" by Kartesz and Meacham (1999) by citing Smith (1988). [The species was now excluded, as the record was not backed with a known voucher.]

Cucurbita maxima Duchesne (Cucurbitaceae) -This species was excluded by Smith (1988) referring to cultivated material from Newton Co. collected by Ralph Thompson in 1977; reinstated erroneously by Kartesz and Meacham (1999) based on Smith (1988). The species is not known in Arkansas beyond cultivation.

Cyperus thyrsiflorus Junghahn (Cyperaceae)—Kartesz and Meacham (1999) listed this species for Arkansas, based on a text passage in a monograph on Central and South American species (Tucker 1994). There are neither dots, maps, nor vouchers supporting this record. In Vol. 23 of Flora North America, on p. 185, the species was not mapped for Arkansas but occurs in the Gulf states to the south.

Desmodium canadense (L.) DC. (Fabaceae) — This species was reported by Demaree (1943), listed as not yet known from the state but "possible" by Smith (1978, 1988). The species does not in Arkansas according to Isely (1998), but is found to the north in Missouri and northeastern North America. Kartesz and Meacham (1999) considered it "?present" in Arkansas, citing "Gleason (1963)" [1952? or Gleason and Cronquist, 1963?] Without a known and valid voucher, the species remains excluded from the flora.

Drosera intermedia Hayne (Droseraceae)—This species was reported from Conway Co. by Moore (1951); Smith (1968) excluded this species as it was based on misidentification of *D. brevifolia* Pursh. The species was reinstated erroneously by Kartesz and Meacham (1999) by citing Smith (1968).

Eragrostis elliottii S. Wat. (Poaceae)—Kartesz and Meacham (1999) listed this species for Arkansas, citing the revised Flora of Missouri by Yatskievych (1999), who cited Texas manuals by Gould (1975) and Correll and Johnson (1970). A known voucher is lacking.

Erigeron philadelphicus L. var. **philadelphicus** (Asteraceae)—Branner and Coville (1891) listed this variety for Arkansas without citing a voucher. Efforts since Buchholz and Palmer (1926) have failed to locate a known and valid voucher. Kartesz and Meacham (1999) listed this variety for Arkansas, citing only the compiled list of Demaree (1943).

Erigeron pulchellus Michx. var. **pulchellus** (Asteraceae)—Branner and Coville (1891) listed this variety for Arkansas without citing a voucher. Efforts since Buchholz and Palmer (1926) have failed to locate a known and valid voucher. Kartesz and Meacham (1999) listed this variety for Arkansas, citing only the compiled list by Demaree (1943).

Eupatorium album L. var. **album** (Asteraceae)—Branner and Coville (1891) listed tnis variety for Arkansas without citing a voucher. Efforts since Buchholz and Palmer (1926) have failed to locate a known and valid voucher. Kartesz and Meacham (1999) listed this variety for Arkansas, citing only the compiled list by Demaree (1943).

Eustoma exaltatum (L.) Salib. ex G. Don subsp. **russellianum** (Hook.) Kartesz (Gentianaceae)—This variety was reported for Arkansas by Moore (1951). Shinners (1957) corrected the varietal name to *E. exaltatum* (L.) Salisb. subsp. *exaltatum*. The change was noted by Smith (1988) and the Arkansas Natural Heritage Commission. The incorrect variety was re-instated by Kartesz and Meacham (1999) as "present" and by citing the ANHC. Kartesz and Meacham (1999) also listed the correct varietal name for the species in Arkansas.

Glycyrrhiza lepidota Pursh (Fabaceae)—This species was reported by Branner and Coville (1891), compiled by Demaree (1943), and noted by Steyermark (1963). It was only listed as "possible" in Arkansas by Smith (1978,1988) as a voucher was not found. It was not mapped in Arkansas by Isely (1998). The species was erroneously listed by Kartesz and Meacham (1999) by citing only the compiled list by Demaree (1943).

Hieracium marianum Willd. (Asteraceae)—Kartesz and Meacham (1999) listed this species for Arkansas based on personal communication with Guy Nesom. Nesom does not recollect this communication, but thinks that this record is unlikely (pers. comm. Guy Nesom). Lacking a known voucher, the spe cies was excluded.

Humulus japonicus Sieb. & Zucc. (Cannabaceae)—This exotic and weedy species was listed as "present but extinct" in Arkansas by Kartesz and Meacham (1999), who cited Flora of North America (Vol. 3). Lacking a known voucher, the species was excluded.

Hydrophyllum macrophyllum Nutt. (Hydrophyllaceae)—All prior reports, such as in Smith (1988) are misidentified material of recently named *Hydrophyllum brownei* Kral & Bates. The species was erroneously re-instated for Arkansas by Kartesz and Meacham (1999) along with the correct species, *H. brownei*.

Lindera benzoin (L.) Blume var. **benzoin** (Lauraceae)—This variety was first reported by Branner and Coville (1891), compiled by Demaree (1943), but not mapped by Tucker (1976). Smith (1978, 1988) who assigned all Arkansas material to *L. benzoin* var. *pubescens* Willd., but the incorrect variety was reinstated by Kartesz and Meacham (1999) who cited Demaree (1943).

Linum lewisii Pursh var. **lewisii** (Linaceae)—The variety was listed by Branner and Coville (1891), compiled by Demaree (1943), excluded by Smith (1988) noting that Rogers (1963) mapped the species no closer than north-central Mississippi. Kartesz and Meacham (1999) reinstated this species as "?present" based on an "unattributed personal communication."

Lobelia puberula Michx. var. **puberula**

(Campanulaceae)—Branner and Coville (1891) listed this variety for Arkansas without citing a voucher. Efforts since Buchholz and Palmer (1926) have failed to locate a known and valid voucher. Kartesz and Meacham (1999) listed this variety for Arkansas, citing only the compiled list by Demaree (1943).

Lobelia siphilitica L. var. **ludoviciana** A. DC. (Campanulaceae)—This variety was reported by Demaree (1943) based on his own collections; listed for the state by Kartesz and Meacham (1999) citing Demaree (1943). All herbarium material in Arkansas and at BRIT with this name on Demaree collections was annotated as var. *siphilitica* by R. L. Wilbur, Duke University, in 1969.

Lonicera reticulata Raf. (Caprifoliaceae)—This species was reported by Demaree (1943) as *L. prolifera* (Kirchn.) Booth ex Rehd., but a voucher has not been located.; Kartesz and Meacham (1999) listed it as present in Arkansas citing Demaree (1943).

Lycopus ×sherardii Steele [*L. uniflorus* × *virginicus*] (Lamiaceae)—Henderson (1962) mapped this hybrid for Arkansas in the form of a shaded overlap of both parent species, but without dots evident or vouchers cited. Listed for Arkansas by Kartesz and Meacham (1999), based on Henderson (1962).

Lysimachia tonsa (Wood) Wood ex Pax & R. Kunth (Primulaceae)—This species was listed by Demaree (1943) as *Steironema tonsum* (Wood.) Bicknell, but was excluded by Smith (1988) as a voucher was lacking. The species was erroneously reinstated as present by Kartesz and Meacham (1999).

Magnolia pyramidata Bartr. ex Pursh (Magnoliaceae)—This species was reported for Arkansas by Hardin (1972), without voucher citations. Tucker (1976) and Smith (1977, 1988) excluded this species. Kartesz and Meacham (1999) erroneously re-listed this species for Arkansas based on Hardin (1972). No Arkansas vouchers are known. Specimens elsewhere may have small leaves that fit herbarium sheets rather than normal sized leaves of *M. tripetala* (L.) L., leading to misidentifications. Any plant from Arkansas would seem to be extralimital, based on the maps of both species in Little (1976).

Matelea carolinensis (Jacq.) Woods. (Asclepidaceae)—This species was listed by Branner and Coville (1891), compiled by Demaree (1943), and treated as an additional representative of *M. decipiens* (Alexander) Woods. by Smith (1988). The species was reinstated by Kartesz and Meacham (1999) citing only the compiled list by Demaree (1943).

Medeola virginiana L. (Liliaceae)—This species was listed by Branner and Coville (1891), compiled by Demaree (1943), and listed as a "possible addition" but not present by Smith (1988) as vouchers were not found. The species was erroneously reinstated as "present" by Kartesz and Meacham (1999) by citing Smith (1988).

Mirabilis linearis (Pursh) Heimerl (Nyctaginaceae)—This species was listed as *Oxybaphus angustifolia* (Pursh) B.L. Robbins by Branner and Coville (1891), compiled by Demaree (1943), and excluded by Smith (1988) as a voucher was lacking. The species was erroneously re-listed as "?present" by Kartesz and Meacham (1999) citing Smith (1988).

Nymphaea odorata Ait. subsp. **tuberosa** (Paine) Wiersma & Hellquist (Nymphaeaceae)—Kartesz and Meacham (1999) listed this variety for Arkansas, citing a text passage in the Muenscher (1944). Later treatments by Fassett (1957) and Crow and Hellquist (2000) place this variety to the north of Arkansas.

Oenothera nutans Atkinson & Bartlett (Onagraceae)—Kartesz and Meacham (1999) listed this species for Arkansas, citing Dietrich et al. (1997). The species was not mapped in Arkansas, nor do voucher citations list any Arkansas specimens in that reference.

Opuntia humifusa (Raf.) Raf. var. **austrina** (Small) Dress (Cactaceae)—Kartesz and Meacham (1999) listed this variety for Arkansas, citing only the compiled list by Demaree (1943). Great Plains Flora Association (1977) mapped this variety west of Arkansas, again a possible confusion based on Arkansas Territory that included Oklahoma.

Oxydendrum arboreum (L.) DC. (Ericaceae)—This species was first listed by Lesquereux (1860), re-listed by Branner and Coville (1891), listed again by Moore (1941), and compiled by Demaree (1943). It was excluded by Tucker (1976) as a voucher was lacking. It was re-excluded by Smith (1978, 1988). It was erroneously reinstated as "?present" by Kartesz and Meacham (1999). The species is known as a street tree in Arkansas, but it has not escaped.

Paronychia fastigiata (Raf.) Fern. var. **paleacea Fern.** (Caryophyllaceae)—Demaree (1943) reported this variety for Arkansas based on his own collections; Kartesz and Meacham (1999) listed this variety for Arkansas. All Demaree specimens with this name in Arkansas and at BRIT were annotated in 1985 by J. W. Thieret to be var. *fastigiata*, already known from Arkansas.

Pentodon pentandrus (K. Schum.) Vatke (Rubiaceae)—Smith (1988) noted its presence in adjacent counties in Louisiana based on MacRoberts (1988) and suggested that it might be searched for in Arkansas; Kartesz and Meacham (1999) erroneously listed it as "present" in Arkansas, citing Smith (1988).

Physocarpus opulifolius (L.) Maxim. var. **opulifolius** (Rosaceae)—First reported by Buchholz and Palmer (1926) and compiled by Demaree (1943). All Arkansas material was assigned to *P. opulifolius* (L.) Maxim. var. *intermedius* (Rydb.) Robinson by Tucker (1976). Smith (1978, 1988) agreed. Kartesz and Meacham (1999) erroneously reinstated the incorrect variety by citing Demaree (1943).

Physostegia digitalis Small (Lamiaceae)—Kartesz and Meacham (1999) listed this species as "?present" in Arkansas, referring to Cantino (1982). A review of this source shows no text passage mentioning this species in Arkansas, nor map dots in Arkansas, or vouchers.

Plantago major L. (Plantaginaceae)—This species was listed by Branner and Coville (1891), and compiled by Demaree (1943). It was listed as a "possible addition" but not present by Smith (1988) who noted the absence of a voucher. It was erroneously reinstated by Kartesz and Meacham (1999) citing only the compiled list by Demaree (1943).

Polygala verticillata L. var. **verticillata** (Polygalaceae)—Branner and Coville (1891) listed this variety for Arkansas without citing a voucher. Efforts since Buchholz and Palmer (1926) have failed to locate a known and valid voucher. Kartesz and Meacham (1999) listed this variety for Arkansas, citing only the compiled list by Demaree (1943).

Populus ×canadensis Moench. [*P. deltoides* × *nigra*] (Salicaceae)—This cultivated hybrid was listed for Arkansas by Kartesz and Meacham (1999). All specimens of this hybrid in Arkansas are cultivated materials from Washington Co. at UARK.

Populus ×canescens Small [*P. alba* × *tremula*] (Salicaceae)—This cultivated hybrid was listed for Arkansas by Kartesz and Meacham (1999). All specimens of this hybrid in Arkansas are cultivated materials from Newton Co. and Washington Co. at UARK.

Populus ×jackii Sarg. [*P. balsamifera* × *deltoides*] (Salicaceae)—This cultivated hybrid is planted in southern Arkansas, but although persisting and expanding as clones, it is not known from any wild population nor is it escaping from tree farms. The hybrid was listed by Tucker (1976) as present in persistent plantings. Smith (1978, 1988) excluded it from the flora as it had not spread or naturalized. Kartesz and Mecham (1999) erroneously listed it for Arkansas by citing Smith (1988).

Potamogeton epihydrus Raf. (Potamogetonaceae)—Kartesz and Meacham (1999) list this for Arkansas, citing a pers. communication with Robert Haynes. Haynes has no such recollection nor any records documenting a voucher for this record.

Potentilla millegrana Engelm. (Rosaceae)—Robertson (1974) remarked that this species "could" be in Arkansas; based on this passage, Kartesz and Meacham (1999) erroneously listed this species for Arkansas.

Pyracantha coccinea M. Roemer (Rosaceae)—Smith (1988) excluded this species as all known vouchers were based on cultivated

material, such as that at UARK collected by Ralph Thompson from Newton Co. The species was listed erroneously as "present" by Kartesz and Meacham (1999) by citing Smith (1988).

Quercus rubra L. var. **ambigua** (A. Gray) Fern. (Fagaceae)—The variety was listed by Kartesz and Meacham (1999) for Arkansas, based only on the compiled list by Demaree (1943). Tucker (1976) and Smith (1978, 1988) excluded this variety as they considered it to be a trivial name not reflective of geographic variation. Vol. 3 of Flora North America does not use this varietal name.

Quercus ×**humidicola** Palmer [*Q. bicolor* × *lyrata*] (Fagaceae)—This hybrid was listed by Demaree (1943). It was excluded by Tucker (1976) as one of the parents (*Q. bicolor*) is not known from Arkansas; Smith (1978, 1988) concurred. The hybrid was re-listed by Kartesz and Meacham (1999) by citing Demaree (1943). Perhaps some of the confusion can be traced to a specimen cited by Palmer (1948) from Pulaski Co., Illinois, [not Arkansas.]

Quercus ×**incomita** Palmer [*Q. falcata* × *marilandica*] (Fagaceae)—This hybrid was listed as present by Demaree (1943). Materials assignable to this hybrid for Arkansas were misidentified specimens of *Q.* ×*bushii* Sarg. [*Q. marilandica* × *velutina*], according to Palmer (1948, p. 19) and with his annotations made in 1955 at UARK. The hybrid was erroneously re-listed for Arkansas by Kartesz and Meacham (1999).

Ranunculus cymbalaria Pursh (Ranunculaceae)—Kartesz and Meacham (1999) listed this species for Arkansas, citing "Sida 1976." In that source, the species' distribution was summarized in a text passage (Keener, 1976) as including Texas, Oklahoma, Missouri, Illinois, and New Jersey, but not Arkansas; there are no dots or vouchers suggestive of an Arkansas occurrence.

Ranunculus pusillus Poir. var. **pusillus** (Ranunculaceae)—Branner and Coville (1891) listed this variety for Arkansas without citing a voucher. Efforts since Buchholz and Palmer (1926) have failed to locate a known and valid voucher. Kartesz and Meacham (1999) listed this variety for Arkansas, citing only the compiled list by Demaree (1943).

Rhynchospora nivea Boeckl. (Cyperaceae)—This species was first reported for Arkansas in Correll and Johnson (1970). It was probably based on misidentified Arkansas material of *R. colorata* (L.) Pfeiffer. All white-bracted *Rhynchospora* in Arkansas are specimens of *R. colorata*, a larger and coarser species typical of southeastern United States, rather than the Oklahoma–Texas species that is smaller and finer in form.

Rudbeckia bicolor Nutt. (Asteraceae)—Branner and Coville (1891) listed this species for Arkansas without citing a voucher. Efforts since Buchholz and Palmer (1926) have failed to locate a known and valid voucher. Kartesz and Meacham (1999) listed this variety for Arkansas, citing only the compiled list by Demaree (1943).

Salix amygdaloides Anderss. (Salicaceae)—This species was reported by Smith (1978, 1988) for Crittenden Co., Arkansas, but it was excluded by Argus (1986) as it was based on a misidentified specimen of *S. eriocephala*. Great Plains Flora Association (1977) mapped it in Franklin Co., Arkansas, but it was excluded by Argus (1986) as the specimen was collected in Franklin Co., Kansas.

Scutellaria incana Biehler var. **punctata** (Chapman) C. Mohr (Lamiaceae)—Kartesz and Meacham (1999) listed this variety for Arkansas, citing Fernald (1950). Epling (1942) does not map this variety in Arkansas, but does map *S. incana* Biehler var. *incana*. Lacking a known and valid voucher, this variety was excluded from the state flora.

Scutellaria nervosa Pursh (Lamiaceae)—Kartesz and Meacham (1999) listed this species for Arkansas, citing only the compiled list by Demaree (1943). Epling (1942) does not map this species in Arkansas. Lacking a known and valid voucher, this species was excluded from the state flora.

Sesuvium verrucosum Raf. (Aizoaceae)—This species was reported for Arkansas by Smith (1978, 1988), but without a voucher, referring to text passages in Correll and Johnson (1970). As a known and valid voucher has

not been found in the last 30 years, this species was excluded from the flora of Arkansas.

Smilax illinoensis Mangaly (Smilacaceae)—Kartesz and Meacham (1999) reported this species for Arkansas based on Mangaly (1968). Mangaly (1968) did not report *S. illinoensis* in Arkansas. A clerical error was made in reading Map 22 on p. 75, wherein a dot for *S. pulverulenta* was incorrectly assigned to *S. illinoensis*.

Sporobolus airoides (Torr.) Torr. (Poaceae)—This species was reported by Buchholz and Palmer (1926), compiled by Demaree (1943), reported with a voucher by Smith (1977). It was then reported as misidentified material of *Sporobolus cryptandrus* (Torr.) A. Gray by Smith (1988). It was tracked by Arkansas Natural Heritage Commission under the species historic name. It was reinstated erroneously by Kartesz and Meacham (1999) as "present" by citing only the compiled list by Demaree (1943) and ANHC.

Tridens muticus (Torr.) Nash var. **muticus** (Poaceae)—This variety was listed by Demaree (1943) as *Triodia mutica* (Torr.) Scribn., and compiled as present by Kartesz and Meacham (1999) citing Demaree (1943). The variety was excluded, as the record lacks a known and valid voucher.

Utricularia cornuta Michx. (Lentibulariaceae)—Kartesz and Meacham (1999) listed this species for Arkansas, citing Taylor (1989). Text passages state that this species was in Arkansas, but other passages state that its distribution is in the southern Gulf Coastal Plain (Florida to Texas), not Arkansas. As a known and valid voucher is lacking, the species was excluded.

Utricularia striata LeConte ex Torr. (Lentibulariaceae)—Kartesz and Meacham (1999) listed this species as present for Arkansas, citing text passages in Correll and Johnson (1970). Taylor (1989) did not list it for Arkansas. Lacking a known and valid voucher, the species was excluded.

Verbena ×deamii Moldenke (Verbenaceae)—This hybrid was listed by Kartesz and Meacham (1999) for Arkansas based only on the compiled list by Demaree (1943). The hybrid occurs to the north of Arkansas (Moldenke, 1980). A voucher has not been located in Arkansas or at BRIT.

Viola arvensis Murr. (Violaceae)—This species was listed for Arkansas by Branner and Coville (1891), compiled by Demaree (1943), but excluded from Arkansas in Russell (1965), and re-excluded in Smith (1978, 1988), who noted the absence of a voucher. It was reinstated erroneously by Kartesz and Meacham (1999) by citing only the compiled list by Demaree (1943).

Zanthoxylum hirsutum Buckl. (Rutaceae)—This species was reportedly in Arkansas according to Correll and Johnson (1970). It was relisted by Kartesz and Meacham (1999). All shrubby material in Arkansas is assignable to *Z. americanum* P. Mill.; larger plants are *Z. clava-herculis* L. (Tucker 1976).

ACKNOWLEDGMENTS

Thanks are expressed to John Kartesz and Chris Meacham for their efforts and assistance in extracting the Arkansas data from their helpful and powerful national database. Thanks are expressed to BRIT, MO, and UARK herbaria directors and staff for their assistance and dedication to floristic efforts, to the ANHC director and staff for their assistance and excellent record keeping, and to my fellow members and representatives of the Arkansas Vascular Flora Project. The author welcomes being informed of vouchers that would clarify the status of these plants in Arkansas.

(b/w photos, graphs, maps), tables, 7" × 10".

From Taylor & Francis website.—"*Oregano - The genera Origanum and Lippia* is an analytic review on the currently available technical knowledge and market information on the world's commercially most valued spice. The book treats in detail various aspects of practical significance for the crops industrialization - such as optimizing germplasm selection and utilization, novel cultivation methods and product processing, blending and uses in different countries, along with other market related issues never included in previous reviews. Extensively referenced and including a special guide to electronic data retrieval strategies, this volume is the definitive source of information for anyone interested in the research in, and application of, *Oregano* across both academia and industry.

Contents.—**PART 1:** Introduction; **1)** Profile of the multifaceted prince of the herbs. **PART 2:** Botany; **2)** Structural features of *Origanum* sp. **PART 3:** Taxonomy and chemistry; **3)** The taxonomy and chemistry of *Origanum*; **4)** The Turkish *Origanum* species; **5)** The chemistry of the genus *Lippia* (Verbenaceae). **PART 4:** Cultivation and breeding **6)** Cultivation of Oregano; **7)** Breeding of Oregano. **PART 5:** Pharmacology; **8)** The biological/pharmacological activity of the *Origanum* genus. **PART 6:** Uses of Oregano in the food industry; **9)** Processing, effects and use of Oregano and marjoram in foodstuffs and in food preparation. **PART 7:** Biotechnology; **10)** The biotechnology of Oregano (*Origanum* sp. and *Lippia* sp.). **PART 8:** Miscellaneous; **11)** Bibliometric analysis of agricultural and biomedical bibliographic databases with regard to medicinal plants genera *Origanum* and *Lippia* in the period 1981–1998; and Index.

NORTHWARD RANGE EXTENSION IN FLORIDA OF THE INVASIVE FERN *LYGODIUM MICROPHYLLUM* (LYGODIACEAE)

Robert W. Pemberton

Invasive Plant Research Laboratory
USDA-Agricultural Research Service
3205 College Ave.
Ft. Lauderdale, FL 33314, U.S.A.

ABSTRACT

A newly recognized population of the dangerous invasive fern *Lygodium microphyllum* has been found in Orange County in central Florida. This population of the weed is known to have persisted within a cypress swamp for almost 15 years, during which time the area experienced single or multi-night freezes of -2.5 to -5.5°C. This finding indicates that the weed could live in other USDA Cold Hardiness Zone 9 areas such as southern Texas, which the fern may be able to reach via its wind-borne spores.

RESUMEN

Se encontró en el Condado de Orange, en el centro de la Florida, una población reconocida recientemente del helecho invasivo y peligroso, *Lygodium microphyllum*. Se sabe que esta población de maleza ha persistido durante 15 años en una ciénaga de ciprés donde fue encontrado, durante tal periodo de tiempo el área experimentó heladas de -2.5 hasta -5.5°C durante una o más noches. Esta observación indica que la maleza podría vivir en otras áreas de la Zona de Resistencia al Frío (USDA) Numero 9, tal como el sur de Tejas, área que el helecho puede alcanzar por las esporas llevadas por el viento.

Lygodium microphyllum (Cav.) R.Br. (Lygodiaceae), known as Old World climbing fern, is considered to be the most serious weed of swamps and other moist habitats in southern Florida (Pemberton & Ferriter 1998). The weed is a severe problem because it dominates and displaces native vegetation, is spreading rapidly, and lacks adequate or affordable control measures. The fern is native to the Old World subtropics and tropics (Pemberton 1998), and was first found to be naturalized in Martin County in 1965 (Beckner 1968). Since then, the plant has spread to infest numerous susceptible habitats in all the Florida counties south of the northern shore of Lake Okeechobee. The weed covered an estimated 40,500 ha in Florida as of 1999 (A. Ferriter pers. comm.), and has expanded considerably since then. For instance, the infestation in Everglades National Park was estimated to occupy 810 ha in December 2002, but ca. 4,050 ha in August, 2003, despite aggressive aerial spraying with herbicides (T. Pernas and J. Taylor pers. comm.). The fern occurs much more sporadically north of Lake Okeechobee but is becoming more abundant. Prior to this report, the known northern limits of *L. microphyllum* were near Nalcrest in southeast Polk County and at a site in southern Brevard County (Pemberton & Ferriter 1998), both at

SIDA 20(4): 1759–1761. 2003

ca. 27° 50' latitude. The Brevard County population is probably recent, first detected in 1997 (specimen sent to and confirmed by the author by M.A. Poole), but the Polk County population was present at least since 1979, when a herbarium sample (*Willson 353*, FLAS!) was collected.

During January 2003, an unrecognized population of *L. microphyllum* was examined in a cypress swamp east of Orlando. This site, at 28°30'42"N, represents a 70 km northern range extension of the plant.

Voucher specimens: **U.S.A. Florida. Orange Co.:** Eastern Service Area Wetland Treatment Facility on the W side of Alafa, Trail, 3 km S of Hwy. 408, ca. 8 km E of Orlando, along the boardwalk growing on bald cypress and other plants within the swamp, 27 Jan 2003, *Robert Pemberton s.n.* (USF).

Patches of the fern are present across an area of ca. 2 ha within the site, where the fronds twine up cypress tree trunks, *Taxodium distichum* (L.) Rich. forming large skirts consisting of living intertwined fronds layered over dead but persistent strands of rachis ("stems"). The large size of these skirts, like those in the long-established populations of the weed in southern Florida, indicates that this Orange County population is not new. *Lygodium microphyllum* was found during a vegetation analysis of this wetland during 1989, 1990, and 1991, but misidentified as *Lygodium japonicum* (Thunb.) Sw. (L. Swartz , Camp Dresser and McKee Inc., here forth CDM Inc., unpublished reports). *Lygodium japonicum* is the other invasive climbing fern that has naturalized in Florida, and the two species are often confused. *Lygodium japonicum* rarely occurs in deeper wetlands such as swamps, but it can't survive constant standing water like *L. microphyllum*. *Lygodium japonicum* has sterile pinnules ("leaflets") that are lobed or dissected, whereas *L. microphyllum* only occurs at wet sites in Florida and has sterile pinnules that are usually unlobed. Furthermore, *L. japonicum* is common in northern and central Florida (and occurs widely in the Southern states), but *L. microphyllum* occurs, with a few exceptions such as this one, in the southern third of Florida.

The occurrence of this newly recognized population of *L. microphyllum* in the northern part of Orange County, and its persistence for almost 15 years, demonstrates the plant's ability to tolerate significant single-night freezes. This population, which was first found by CDM Inc. staff during July1989, survived the 1989 Christmas freeze when temperatures dropped to -2.5–5.5°C during the three day period (Orlando International Airport Weather Station #6628 records). On all three dates (Dec. 23, 24, and 25), the daytime temperatures climbed above freezing. The airport is ca. 13 km to the southwest of the population. This more northerly occurrence indicates that the plant's ability to endure lower temperatures of short duration is greater than previously recognized. The observations suggest that *L. microphyllum* may be able to colonize additional areas in central Florida, and probably northward, especially along the relatively mild east coast of the state. The fact that *L. microphyllum* has not come to dominate the Orange County cypress swamp, despite being there for ca. 15 or more

years, suggests that the weed is not as aggressive in central Florida as it is in southern Florida. The ability of this fern to colonize and persist in central Florida, in USDA-Cold Hardiness Zone 9 (Cathey 1990), as well that wetlands in southern Texas and Louisiana are climatically suitable for the weed. The plant produces large numbers of spores and occurs on many oceanic islands within its native range both of which suggest that it may be able to reach these areas via its wind-borne spores (Pemberton & Ferriter 1998). Because this fern's gametophytes are self fertile (Lott et al. 2003), only one spore is needed to start a new infestation. Biological control may have the potential to control this weed (Pemberton, 1998); a suite of specialist insect and mite herbivores is currently being evaluated (Pemberton et al. 2002; Goolsby et al. 2003).

ACKNOWLEDGMENTS

I wish to thank J. B. Lee and L. Swartz, CDM Inc., Maitland, Florida, for providing access to the infested swamp and for information from CDM reports on the vegetation monitoring at the site. Amy Ferriter, South Florida Water Management District and Tony Pernas and Jonathan Taylor, Everglades National Park, kindly shared estimates of *L. microphyllum* abundance. Paul Pratt, USDA-ARS, Ft. Lauderdale, read and improved an earlier draft of this note, and Forest W. Howard, Univ. Florida, Davie, wrote the Spanish language abstract. Kathy Burks, Florida Department of Environmental Protection, Tallahassee, and Colette Jacono, U.S. Geological Survey, Gainesville, FL provided knowledgeable reviews of the manuscript for Sida, which helped me produce better final version.

Contents.—**1)** General introduction: **PART I;** *Geranium;* **2)** History of nomenclature, usage and cultivation of *Geranium* and *Pelargonium* species; **3)** The taxonomy of *Geranium* species and cultivars, their origins and growth in the wild; **4)** Phytochemistry of the genus *Geranium;* **5)** Cultivation and harvesting of *Geranium macrorrhizum* and *Geranium sanguineum* for medicinal use in Bulgaria; **6)** Essential oil of *Geranium macrorrhizum* L. production, extraction, distillation **and** use; **7)** Use of *Geranium* species extracts as herbal medicines. **PART 2;** *Pelargonium;* **8)** The taxonomy of *Pelargonium* species and cultivars, their origins and growth in the wild; **9)** Cultivation and sales of *Pelargonium* plants for ornamental use in **the** UK and worldwide; **10)** Growing pelargoniums in the garden, conservatory and for shows; **11)** Phytochemiistry of the genus *Pelargonium;* **12)** Pharmacology of Pelargonium essential oils and extracts *in vitro and in vivo.* **13)** Antimicrobial properties of *Pelargonium* extracts contrasted with that of *Geranium;* **14)** Essential oils from different *Pelargonium* species and cultivars: their chemical composition (using GC, GC/MS) and appearance of trichomes (under EM); **15)** Chemotaxonomy of *Pelargonium* based on alkaloids and essential oils, **16)** Phylogentical relationship within the genus *Pelargonium* based on the RAPD-PCR method of DNA analysis correlated with the essential oil composition; **17)** Geranium essential oil: standardisation, ISO; adulteration and its detection using GC, enantiomeric columns, toxicity and bioactivity; **18)** 'Rose-scented geranium' a *Pelargonium* grown for the perfume industry; **19)** Cultivation and distillation of Geranium oil from *Pelargonium* species in India; **20)** Micropropagation and biotechnological approaches to tissue culture of *Pelargonium* species and production of essential oils of scenteds; **21)** Geranium oil and its use in aromatherapy; **22)** Perfumery and cosmetic products utilising Geranium oil; **23)** New research: possible uses of various *Pelargonium* leaf oils and extracts as food preservatives; **24)** *Pelargonium reniforme* and *Pelargonium sidoides*: their botany, chemistry and medicinal use; **25)** Interactions between arthropod pests and pelargonium; **26)** Correlation of the chemical profiles of the essential oil of *Pelargonium* (Geranium oil) and others separately and in mixes, with their relaxant or stimulant properties in man and smooth muscle preparations *in vitro*; and Index.

MUHLENBERGIA DUBIA (POACEAE) IN CENTRAL TEXAS

Geoffrey C. Denny[1]
Plant Resources Center
University of Texas
Austin, TX 78713, U.S.A.

Muhlenbergia dubia Four. ex Hemsl. is a wide ranging species known from Texas and New Mexico, south through northeastern and north central Mexico to Michoacán, the state of México, Puebla, Oaxaca, and Veracruz (Correll & Johnston 1970; Gould 1975; Powell 1994; Herrera-Arrieta 2001). In Texas, it has been considered to be confined the Trans-Pecos region (Correll & Johnston 1970; Gould 1975; Powell 1994). It is a species primarily found on rocky hilltops and canyons in open oak-juniper/pine woodlands.

In 1912, M.E. Jones described a new species, *Muhlenbergia metcalfei*, from Grant County, New Mexico. Hitchcock (1951), Gould (1975), Powell (1994), and Jones et al. (1997) recognized *M. metcalfei* as distinct from *M. dubia* Four. ex Hemsl. and *M. rigida* (Kunth) Kunth. These two species are often difficult to distinguish from each other and both are reported as occurring in trans-Pecos Texas. However, Correll and Johnston (1970) and Martin and Hutchins (1980) recognized *M. metcalfei* as synonymous with *M. dubia*. Powell (1994) only tentatively recognized these taxa as distinct 'pending further studies.' He commented that it is 'difficult to defend specific status for such close entities with sympatric distribution.' Peterson et al. (2001) reduced *M. metcalfei* to synonymy with *M. rigida* (Kunth) Kunth in their synopsis of Poaceae, subfamily Chloridoideae, however, the reasons for this taxanomic placement are not presented.

There is no published record of *Muhlenbergia dubia* in central Texas. However, during field work for a flora of the Nature Conservancy of Texas' Love Creek Nature Preserve in Bandera County, Texas in the southern Edwards Plateau, *M. dubia* was collected by the author. Surveys conducted revealed numerous, large populations primarily in the uplands of the preserve, a habitat very similar to habitats in which the species occurs throughout its range. The original specimens were collected from a population on a sloping, open area with various grasses, scattered *Sophora secundiflora* (Ortega) Lag. ex DC, *Juniperus ashei* J. Buchholz, and *Diospyros texana* Scheele, and a few individuals of *Quercus fusiformis* Small and cacti. The substrate was a very thin, rocky, limestone soil. Subsequent collections were made from five other populations on the preserve, and one on a roadside that is very similar in habitat in Kerr County, Texas.

A review of the TEX, LL and TAES herbaria revealed that *Muhlenbergia*

[1]Current address: Dept. of Horticultural Sciences, Texas A&M University, College Station, TX 77843-2133, U.S.A. gcdenny@tamu.edu.

SIDA 20(4): 1763–1764. 2003

dubia actually was collected on the Edwards Plateau as early as 1967. A specimen of *M. dubia*, identified as *M. metcalfei*, from Edwards County, Texas, on the western edge of the Edwards Plateau, was collected in 1967 by Albert Jenkins. A specimen of *M. dubia* was collected by M.C. Johnston in Travis County, Texas in 1977. It was, however, originally misidentified as *M. rigens*, a similar species also from the trans-Pecos area of Texas. The existence of *M. dubia* on the Edwards Plateau of Texas is also known to the native plant nursery industry in central Texas (Dan Hosage, pers. comm.). Additional specimens should be expected from other counties throughout the Edwards Plateau. The species is relatively easy to distinguish from other central Texas species of *Muhlenbergia* by its contracted panicles, densely caespitose habit, and rounded, erect culms.

ABSTRACT

Naturalized populations of the Asian amphibious species *Rotala rotundifolia* are documented for three peninsular Florida counties. Distinguishing characters and a comment on invasive potential are also provided.

RESUMEN

Se documentan las poblaciones naturalizadas de la especie Asiática anfibia *Rotala rotundifolia* para tres condados de Florida peninsular. Se presentan también caracteres distintivos y un comentario acerca del potencial de invasión.

Rotala rotundifolia (Buch.-Ham. ex Roxb.) Koehne is a creeping amphibious perennial found mostly in mountainous areas across a broad native range extending from India to Japan and China (Cook 1979; TROPICOS 2003). It has been widely available in the international aquarium trade for more than three decades (e.g., Roe 1967; Stodola 1967) and more recently promoted in the water garden trade (e.g., Schuck 2000). "Dwarf Rotala," as it is often called in the trade, was first collected in Florida as an established escape in 1996 by the second author while consulting with water managers in the City of Coral Springs, Broward County in southeast Florida. A robust stand was spreading along the edge of a flood-control canal coursing through a residential area. Samples of naturalized populations have since been collected from a second canal location in Coral Springs, a flood-control canal in Palm Beach County to the north, and flood-control canals in the community of Lehigh Acres, Lee County in southwest Florida (Fig. 1).

Representative specimens: **FLORIDA. Broward Co.:** Coral Springs, one block N of Sample Road, in and along edge of canal about 46 m E of the intersection of Cardinal Road (NW 40th Street) and Woodside Drive, N26.2793 W80.2285, 8 Mar 1996, *Vandiver s.n.* (FLAS); Coral Springs, in and along

SIDA 20(4): 1765–1769. 2003

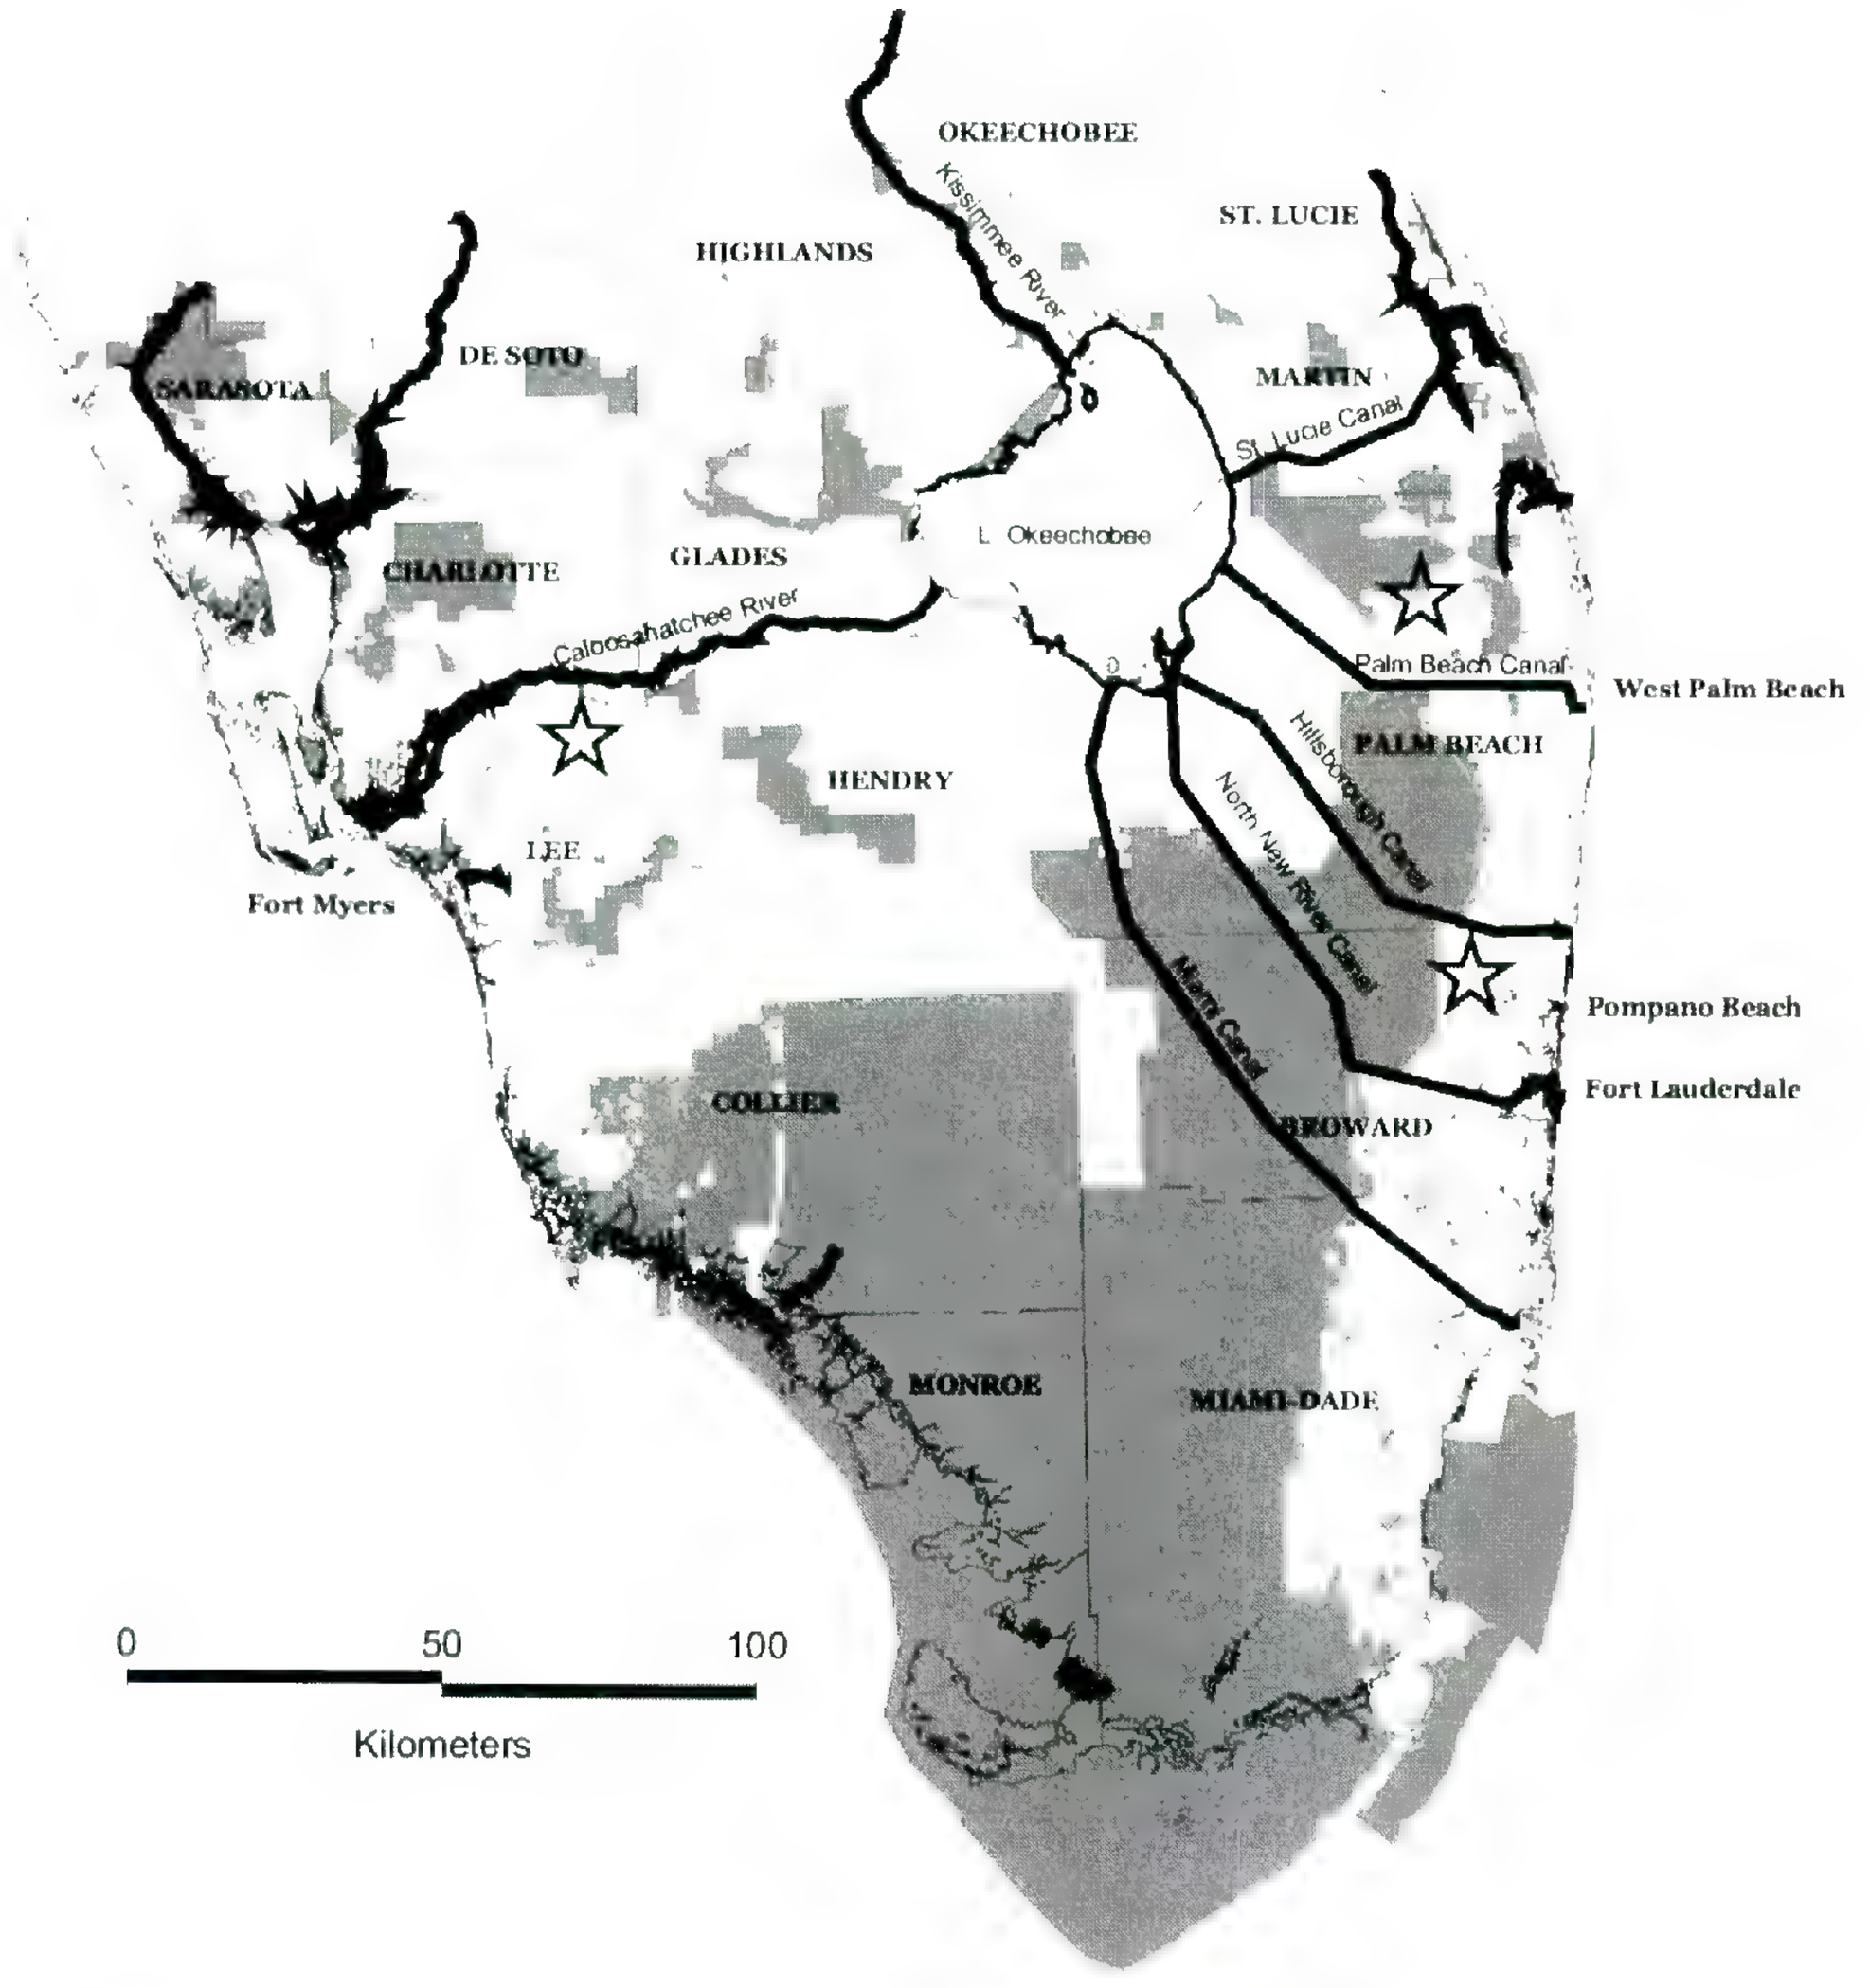

Fig. 1. Florida distribution of *Rotala rotundifolia* (stars). Each star marks two or more populations within a particular canal system (see text). Gray areas delineate public conservation lands (federal, state, local, and non-governmental).

W bank of canal on E side of Cypress Park, E side of Coral Springs Drive, 0.5 km S of Ramblewood Drive, N26.2476 W80.2662, 4 Apr 2000, *Vandiver s.n.* (FLAS, NY, SWSL, USF). **Lee Co.:** Lehigh Acres, S bank and shallows of Able Canal, N26.6118 W81.6412, 12 Apr 2002, *Jacono 418* (FLAS); 10 Jun 2002, *Burks 1215* (FLAS, FSU, FTG, USF). **Palm Beach Co.:** Indian Trail Improvement District, N of Loxahatchee and Lion Country Safari, Development Unit 5, two blocks S of North Lake Boulevard (CR-809A), in floating mats by culvert at the intersection of Hamlin Boulevard and District's "I" Canal (formerly 170th Avenue), N26.8089 W80.3114, 12 Jun 2001, *Vandiver s.n.* (FLAS, USF, Z).

Additional small patches or mats were noted in connecting canals of the Indian Trail system, Palm Beach County. A June 2002 survey of the Lehigh Acres canal system, Lee County, revealed additional patches at the junction of Charlie Diversion and Hickey Creek Canals (N26.6435 W81.6626) and on the east side of Harns Marsh, a filtration impoundment (N26.6520 W81.6872); none was

found at the outfall to the Orange River, a natural waterway that is part of the Caloosahatchee River basin. In North America, the species is known from just one other point of introduction—Tuscaloosa, Alabama, where it is well established around a campus pond (Haynes 2002, 2003 pers. comm.).

Only two congeners of this species are known to occur in the continental United States and Canada: the widespread native "toothcup," *Rotala ramosior* (L.) Koehne, and another introduced Asian species, *Rotala indica* (Willd.) Koehne, which is known from rice field edges in Butte County, California (Mason 1957; Oswald 1994) and in five parishes of Louisiana (Thieret 1972 [*Thieret 33544*, 1972, FLAS! FSU!]; R. D. Thomas [NLU] 2000 pers. comm.). All three species are low growing, glabrous herbs found in or near water; the leaves are decussate or rarely in whorls of three. *Rotala rotundifolia* (Fig. 2) is easily distinguished by a usually perennial habit; emersed leaves obovate to orbicular, to 2 cm long and 2.5 cm wide; a conspicuous rose-pink inflorescence of small spike-like racemes that elongate and become lax in post-anthesis; and 4-valved capsules (Cook 1979, 1990; Graham 1975; Reed 1977).

In the water-plant trade, *R. rotundifolia* has sometimes been confused with *R. indica* (e.g., Schuck 2000) and with an endemic of southwest India, *Rotala macrandra* Koehne (see discussion in Benl 1972). The annual *R. indica* has leaves with distinct cartilaginous margins, solitary flowers or short lateral spikes in upper leaf axils, calyx tubes longer than broad, and 2-valved capsules (Cook 1979). The Indian plant *R. macrandra* is much like *R. rotundifolia* in form and habit, but its submersed leaves are usually longer, to 2.5 cm, with their bases remaining more rounded (Rataj & Horeman 1977). Also, *R. macrandra*'s spike-like racemes usually remain dense in fruit, not elongated, and its stamens and styles are long exserted from the calyx tube (Cook 1979).

Presently, the naturalized populations of *Rotala rotundifolia* on Florida's east coast are much reduced in size—though not entirely eradicated—having responded well to routine tools of chemical control for aquatic plants that may impede water flow in these canal systems. Aquatic-label glyphosate and the aquatic-granular form of 2,4-dichlorophenoxyacetic acid have proven to be the most successful herbicides in stopping the spread of plants (2003 pers. comm., T. Narrow, N. Sculy). Multiple tools are used in the canals, including sterile triploid grass carp, or white amur (*Ctenopharyngodon idella* (Valenciennes)), as a biocontrol agent. However, these herbivorous fish apparently are not inclined to eat this species; they have been observed nibbling at submersed foliage of *R. rotundifolia* and immediately spitting it out (2003 pers. comm., T. Narrow).

On the west coast in the Lehigh Acres system, the current situation is less encouraging, with significant spread of shoreline patches and floating mats in the canals (2003 pers. comm., K. Waugh). However, managers are trying different tools and continuing to check for plants at the outfall water gates.

Florida's widely separated populations no doubt represent multiple intro-

FIG. 2. *Rotala rotundifolia*, in cultivation at quarantine research garden, Tallahassee, Florida. **a.** Orbicular leaves and spike-like racemes. **b.** Submersed leaves, light green, decussate. Growing in a concrete vat with native marsh plants, this species has competed well and overwintered here for at least 15 years, with occasional spread to damp graveled ground between vats (by fallen stem fragments). Cultivation vouchered by *Hall 1842*, 1988 (FLAS) and *Anderson 15431*, 1995 (FSU).

ductions, most likely by dumping of unwanted aquarium or water-garden material. Within each canal system, the plants have probably spread by floating stem fragments, which root adventitiously at lower nodes. Seeds have been observed in collected plant samples, but their levels of viability and germination under Florida conditions are not known. Cook (1979) considered this species self-incompatible and insect-pollinated based on his cultivation studies.

The proximity of natural waterways and wetland conservation lands to the canal systems (Fig. 1) calls for close monitoring to prevent inadvertent transport of viable stem fragments, and possibly seeds, to natural habitats. More educational effort is also needed to revise the age-old human habit of inappropriate disposal of unwanted goods.

ACKNOWLEDGMENTS

Our thanks go to local resource managers who assisted in the field and shared their experience, Christine Kooienga, Terry Narrow, Nick Sculy, and Ken Waugh; to Rob Kipker for generating the GIS-based map; and to C.D.K. Cook for confirming identification of a duplicate specimen.

From Taylor & Francis website.—"The genus *Magnolia* consists of several medicinally important species most of which come from Far East Asia. Many species of this genus have traditionally been used in China and Japan to treat various illnesses, from simple headaches to complicated cancer, and because of their versatility have more recently been incorporated into commercially successful medicine preparations. And with the revival of interest in herbal and oriental traditional medicines, many of these *Magnolia*-containing preparations have captured a significant proportion of the drug market in the Western countries. In recent years several studies have been performed with *Magnolia* species, resulting in the isolation of a number of bioactive compounds and discovery of new biological and pharmacological activities."

Contents.—**1)** Introduction-The Genus *Magnolia*; **2)** Traditional Medicine and *Magnolia*; **3)** Phytochemistry of the Genus *Magnolia*; **4)** Bioactivity and Pharmacological Aspects of *Magnolia*; **5)** Quality Control of *Magnolia* Bark, **6)** Distribution and Commercial Cultivation of *Magnolia*; and Index.

IN MEMORIAM

CHESTER MORRISON ROWELL, JR.

1925–2003

Jim Blassingame

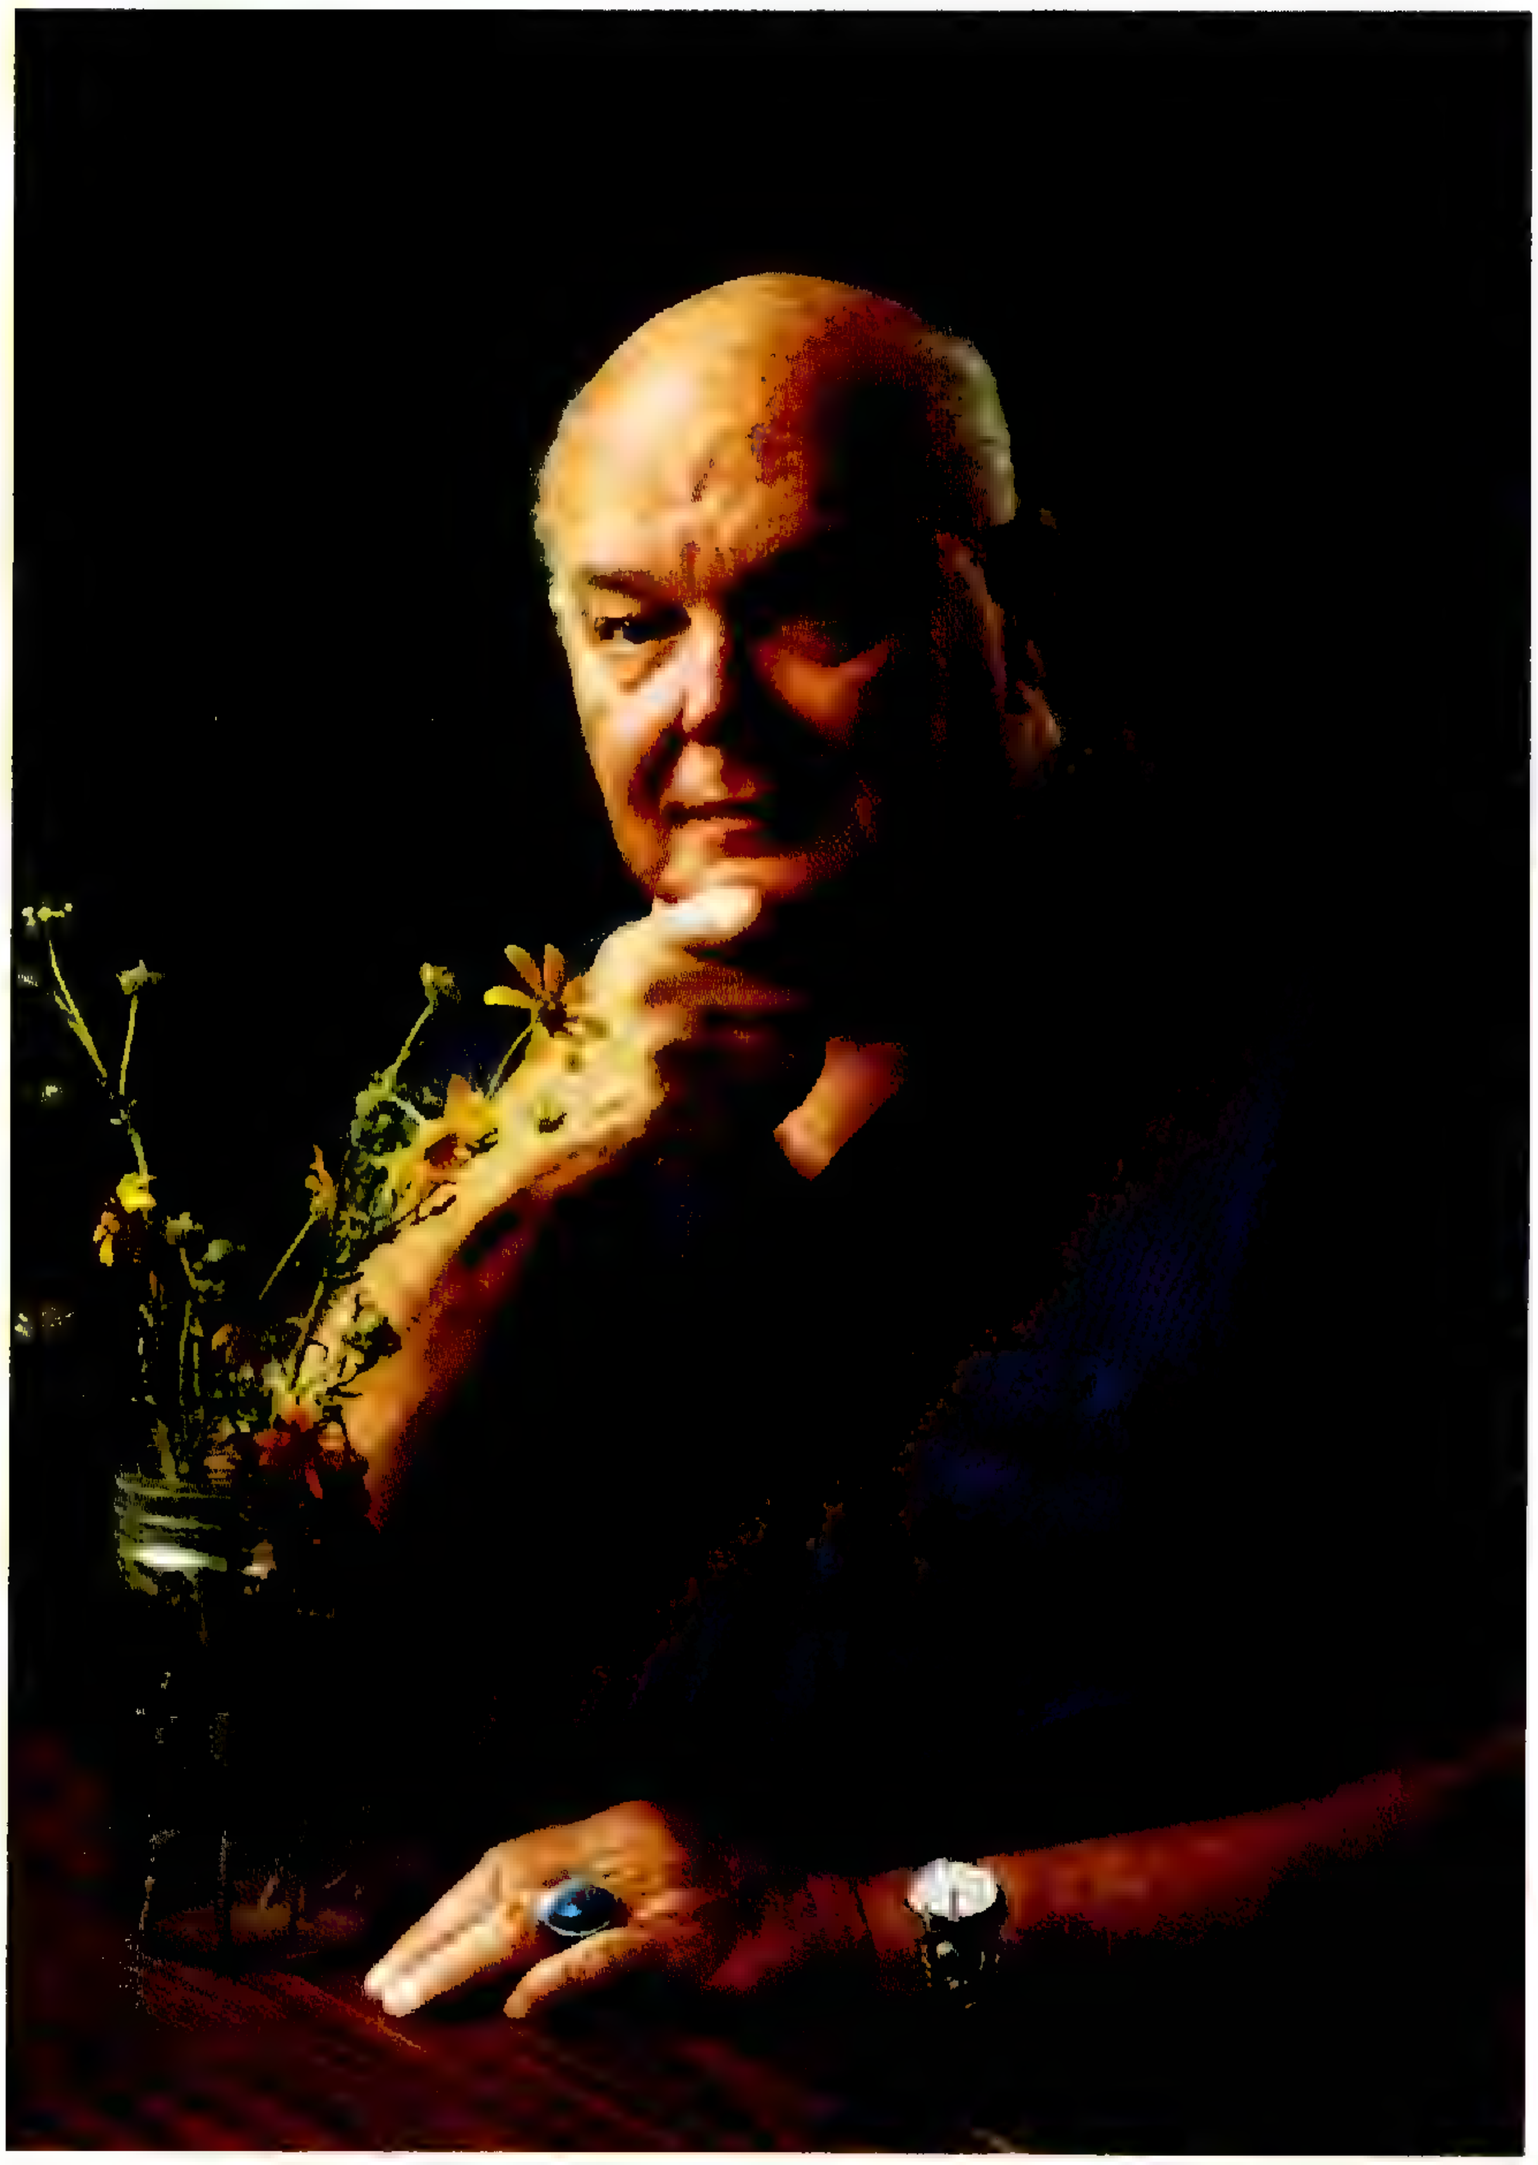
2020 Mustang

Levelland, TX 79336-6704, U.S.A.

The botanical community of Texas expresses its sorrow upon the death of Chester M. Rowell of Marfa, Texas, June 5, 2003.

Chester was born December 2, 1925 in Burnet County, Texas the eldest son of Chester Morrison Rowell and Irene Gahagan Rowell. He received his B.S. from the University of Texas in 1947, his M.S. from Texas A&M University in 1949 and his Ph.D. from Oklahoma State University in 1967.

Chester taught at Texas A & M University from 1949 to 1957, Texas Tech University from 1957 to 1970 and Angelo State University from 1970 to 1987. He was the curator of the herbaria at Texas Tech University and Angelo State University. He served as chairman of the Department of Biology at Angelo State University from 1973 to 1982. After his retirement he was an adjunct Professor of Biology at Sul Ross State University.



Professor Rowell did research on the flora of Southwestern U.S. and Mexico, authored several scientific papers, presented papers at scientific meetings and was author and co-author of two books. Chester was the scientific editor of the Native Plant Society of Texas. Dr. Rowell was a driving force in building the herbaria at Texas Tech University and Angelo State University in to excellent regional collections. He worked on toxic plants and endangered species in Texas. He was an advisor to the Texas Department of Parks and Wildlife for floristic and habitat studies.

Chester was the former President of the Southwestern Association of Naturalists. Dr. Rowell was the recipient of many awards and honors. He was active in professional societies and other organizations.

Dr. Rowell was a respected researcher, valued teacher, dedicated mentor and generous friend to people all around the country. He had a lifelong love affair with photography. His enthusiasm for teaching, learning and scholarship, his quick wit and cooperative spirit, were a role model for all who knew him.

Chester Rowell was a teacher and a friend to all of those interested in the botany of any area. Early in his career he decided that his students should be exposed to life in the field and not just in the laboratory. After this decision

SIDA 20(4): 1771–1772. 2003

Chester M. Rowell (1925–2003)

Chester's life became one continuous field trip or collecting trip. All of his students and friends were given the opportunity many times to partake in such an experience. Chester was very proud to be a professional plant taxonomist. However, he was most proud to be a teacher as a source of stimulation and exciting guide for the intellectual development of young people and friends. He insisted that events of each life should be recorded on film. If you didn't have a camera, he would help you remedy the oversight with encouragement or a gift, usually the latter. Chester enriched the lives of most botanists, photographers, students and friends that he came in contact with.

Chester died June 5, 2003 in Midland, Texas at the age of 77. His many friends and associates will miss him greatly.

BOOK NOTICES

TAYLOR & FRANCIS

Medicinal and Aromatic Plants–Industrial Profiles

Each volume in the series discusses the history and botany of each genus, and provides an in-depth look at areas such as commercial cultivation, chemical and/or pharmacological aspects, toxicology, current and/or future products, etc.

MARIA LIS-BALCHIN (ed.). 2002. **Lavender: The Genus *Lavandula*.** (ISBN 0-415-28486-4, hbk.). **Medicinal and Aromatic Plants–Industrial Profiles. Volume 29.** Series Editor: Roland Hardman. Taylor & Francis, 11 New Fetter Lane, London EC4P 4EE, UK and 29 West 35th Street, New York, NY 10001, U.S.A. (Orders: info@tandf.co.uk, www.tandf.co.uk, 44 (0) 207 583 9855, fax 44 (0) 207-842-2298, standing orders call 44 (0)1264 343071. **US and Canada Customers:** By mail: Taylor & Francis Customer Service, 10650 Toebben Drive, Independence, KY 41051, U.S.A., Toll Free Tel: 1-800-634-7064, Toll Free Fax: 1-800-248-4724, email: cserve@routledge-ny.com). $128.00, 268 pp., numerous b/w photos drawings and tables, 17 color plates 7" × 10".

From Taylor & Francis website.—"With contributions from lavender researchers worldwide, this book will be of interest both to graduate students and scientists in academia and industry who are involved with lavender, to professionals in the lavender growing and retail industry, the perfumery, food and cosmetics industries, and to those interested in lavender for alternative and conventional medical use."

Contents.—**1)** General introduction to the genus *Lavandula;* **2)** The taxonomy of the genus *Lavandula* L.; **3)** History of usage of *Lavandula* species; **4)** History of nomenclature of *Lavandula species*, hybrids and cultivars; **5)** Lavender growing in England for essential oil **production; 6)** The retail lavender nursery; **7)** Lavender growing in Australia; **8)** Naming and misnaming of lavender cultivars; **9)** Phytochemistry of the genus *Lavandula;* **10)** Distillation of the lavender type oils: theory and practice; **11)** Lavender essential oil: standardisation, ISO; adulteration and its detection using GC, enantiomeric columns and bioactivity; **12)** Lavender oil and its therapeutic properties; **13)** Pharmacology of *Lavandula* essential oils and extracts *in vitro and in vivo;* **14)** The psychological effects of lavender; **15)** Antimicrobial properties of lavender volatile oil; **16)** Lavender oil and its use in aromatherapy; **17)** Perfumery uses of lavender and lavaridin oils; **18)** Miscellaneous uses of lavender and lavender oil: use in hair products, food flavouring, tissanes, herbal pillows and medicinal products; **19)** New research into *Lavandula* species, hybrids and cultivars; **20)** Further research into *Lavandula* species: cell cultures of *L. vera* and rosmarinic acid production; **21)** *Lavandula* × *heterophylla* and *L.* × *allardii*: a puzzling complex; **22)** Comparative study of essential oil quantity and composition from ten cultivars of organically grown lavender and lavandin; **23)** Chemical **profiles** of lavender oils and pharmacology; **24)** Chemical composition of essential oils from different species, hybrids and cultivars of *Lavandula*

P.N. RAVINDRAN and K.J. MADHUSOODANAN (eds.). 2003. **Cardamon: The Genus *Elettaria*.** (ISBN 0-415-28493-7, hbk.). **Medicinal and Aromatic Plants–Industrial Profiles. Volume 30.** Series Editor: Roland Hardman. Taylor & Francis, 11 New Fetter Lane, London EC4P 4EE, UK and 29 West 35th Street, New York, NY 10001,

U.S.A. (Orders: info@tandf.co.uk, www.tandf.co.uk, 44 (0) 207 583 9855, fax 44 (0) 207-842-2298, standing orders call 44 (0)1264 343071. **US and Canada Customers:** By mail: Taylor & Francis Customer Service, 10650 Toebben Drive, Independence, KY 41051, U.S.A., Toll Free Tel: 1-800-634-7064, Toll Free Fax: 1-800-248-4724, email: cserve@routledge-ny.com). $128.00, 374 pp., figs. (b/w photos, line drawings, graphs), tables, 7" × 10".

From Taylor & Francis website.—"A textbook and reference work for scientists and students of horticulture, botany and related fields, this book will be the main reference volume on cardamom for many years to come.

Contents.—**1)** Introduction; **2)** Botany, crop improvement and biotechnology of cardamom; **3)** Chemistry of cardamom; **4)** Agronomy and management of cardamom; **5)** Nutrition of cardamom; **6)** Viral diseases of cardamom; **7)** Diseases of cardamom (fungal, bacterial and nematode diseases); **8)** Insect pests of cardamom; **9)** Harvesting and processing of cardamom; **10)** Industrial processing and products of cardamom; **11)** Cardamom economy; **12)** Properties and end-uses of cardamom; **13)** Cardamom - future vision; **14) Yield** gaps and production constraints in cardamom; **15)** Large cardamom (*Amomum subulatum* Roxb.); **16)** False cardamoms; **Appendix 1:** Specification for cardamom; **Appendix 2:** Selected recipes; and Index.

STEPHEN FREER. 2003. **Linnaeus' Philosophia Botanica.** (ISBN 0-19-850122-6, hbk.). Translated from the Latin in 1751 by Stephen Freer. Oxford University Press. (Orders: Oxford University Press, 2001 Evans Road, Cary, NC 27513, U.S.A., 800-451-7556, 919-677-1303 fax, www.oup.com). $277.50, 402 pp., 10 plates with numerous figs., 8 1/2" × 11".

What a fascinating book this is, the translation of Carol Linnaeus' *Philosophia Botanica* (The Science of Botany). The work was originally published in Latin in 1751 in Stockholm and Amsterdam. Stephen Freer's translation is a blessing to botanists, taxonomists, historians, and other interested parties; it gives a new lease on and insight into the work of the father of modern systematics, Carl Linnaeus.—*Barney Lipscomb, Botanical Research Institute of Texas, 509 Pecan St, Fort Worth, TX 76102-4060, U.S.A., barney@brit.org*

EDZARD ERNST (ed.). 2003. **Hypericum: The Genus *Hypericum*.** (ISBN 0-415-36954-1, hbk.). **Medicinal and Aromatic Plants–Industrial Profiles. Volume 31.** Series Editor: Roland Hardman. Taylor & Francis, 11 New Fetter Lane, London EC4P 4EE, UK and 29 West 35th Street, New York, NY 10001, U.S.A. (Orders: info@tandf.co.uk, www.tandf.co.uk, 44 (0) 207 583 9855, fax 44 (0) 207-842-2298, standing orders call 44 (0)1264 343071. **US and Canada Customers:** By mail: Taylor & Francis Customer Service, 10650 Toebben Drive, Independence, KY 41051, U.S.A., Toll Free Tel: 1-800-634-7064, Toll Free Fax: 1-800-248-4724, email: cserve@routledge-ny.com). $120.00, 241 pp., figs. (color and b/w photos, line drawings, graphs), tables, 7" × 10".

From Taylor & Francis website.—"St John's wort (*Hypericum perforatum*) is one of the best-selling herbal medicines worldwide. This landmark book provides a summary of our current knowledge on

a wide range of issues. It covers botany and includes plant infections, cultivation, manufacturing, standardisation, quality control, biochemistry, pharmacology and clinical application. Within this wide range of topics this volume aims to tackle some previously unanswered questions, such as: Which are the pharmacologically active compounds? Is St John's wort effective for severe depression? What are its mechanisms of action? What are the long-term effects and risks? Should St John's wort products be marketed as dietary supplements or as drugs? How does it compare to synthetic drugs for the same indication?"

Contents.—**1)** *Hypericum* botany; **2)** *Colletotrichum gloeosporioides* as the cause of St John's wort (*Hypericum perforatum*) dieback in Switzerland and breeding for a tolerant variety; **3)** A virus causing vein yellowing and necrotic leaf spots of St John's wort (*Hypericum perforatum* L.); **4)** St John's wort herb extracts: manufacturing, standardisation and characterisation; **5)** Culture and biotechnology of *Hypericum*; **6)** Chemical constituents of *Hypericum* ssp.; **7)** Determination of hypericins and hyperforin in herbal medicinal products; **8)** Secondary metabolites content of *Hypericum* sp. in different stages and plant parts; **9)** Herbal medicinal products of St John's wort: manufacturing and quality control; **10)** The potential of *in vitro* cultures of *Hypericum perforatum* and of *Hypericum androsaemum* to produce interesting pharmaceutical compounds; **11)** The clinical pharmacology of *Hypericum perforatum*; **12)** Hypericin as a potential antitumour agent (the work of Professor Kyurig-Tae Lee's group in Seoul); **13)** Neuropsychopharmacological studies on Indian *Hypericum perforatum* Linn; **14)** *Hypericum* in the treatment of depression; and Index.

AMIT KRISHNA DE (ed.). 2003. **Capsicum: The Genus *Capsicum*.** (ISBN 0-415-29991-8, hbk.). **Medicinal and Aromatic Plants–Industrial Profiles. Volume 33.** Series Editor: Roland Hardman. Taylor & Francis, 11 New Fetter Lane, London EC4P 4EE, UK and 29 West 35th Street, New York, NY 10001, U.S.A. (Orders: info@tandf.co.uk, www.tandf.co.uk, 44 (0) 207 583 9855, fax 44 (0) 207-842-2298, standing orders call 44 (0)1264 343071. **US and Canada Customers:** By mail: Taylor & Francis Customer Service, 10650 Toebben Drive, Independence, KY 41051, U.S.A., Toll Free Tel: 1-800-634-7064, Toll Free Fax: 1-800-248-4724, email: cserve@routledge-ny.com). $125.00, 275 pp., figs. (b/w photos, graphs), tables, 7" × 10".

From Taylor & Francis website.—"This book, written by experts, includes material that deals with a variety of aspects, including ethnobotany, chemistry, pharmacology, toxicology, cultivation, analysis, tissue culture and commercial aspects of Capsicum.

Contents.—**1)** *Capsicum*: historical and botanical perspectives; **2)** A glimpse of the world trade in *Capsicum*; **3)** Chemistry and quality control of *Capsicums* and *Capsicum products*; **4)** Pungency principles in *Capsicum* - analytical determinations and toxicology; **5)** Biosynthesis of capsaicinoids in **Capsicum; 6)** Biotechnological studies on *Capsicum* for metabolite production and plant improvement; **7)** Irrigational aspects of *Capsicum*; **8)** The cultivation and processing of *Capsicum* in India; **9)** The preservation and production of *Capsicum* in Hungary; **10)** Post-harvest handling and processing of *Capsicums*; **11)** Advances in post-harvest processing technologies of *Capsicum*; **12)** The storage of *Capsicum*; **13)** Current requirements on paprika powder for food industry; **14)** Adulterants, contaminants and pollutants in *Capsicum* products; **15)** Colour differences in peppers and paprikas; **16)** Future perspectives of capsaicin research; and Index.

ALISTER D. MUIR and NEIL D. WESTCOTT (eds.). 2003. **Flax: The Genus *Linum*.** (ISBN 0-415-30807-0, hbk.). **Medicinal and Aromatic Plants–Industrial Profiles. Volume 34.** Series Editor: Roland Hardman. Taylor & Francis, 11 New Fetter Lane, London EC4P 4EE, UK and 29 West 35th Street, New York, NY 10001, U.S.A. (Orders: info@tandf.co.uk, www.tandf.co.uk, 44 (0) 207 583 9855, fax 44 (0) 207-842-2298, standing orders call 44 (0)1264 343071. **US and Canada Customers:** By mail: Taylor & Francis Customer Service, 10650 Toebben Drive, Independence, KY 41051, U.S.A., Toll Free Tel: 1-800-634-7064, Toll Free Fax: 1-800-248-4724, email: cserve@routledge-ny.com). $135.00, 307 pp., figs. (b/w photos, line drawings, graphs), tables, 7" × 10".

From Taylor & Francis website.—"This volume is a comprehensive review of the genus covering all aspects of the taxonomy, chemistry, cultivation, pharmacology and commercial uses of flax, and includes chapters on the disease prevention potential of these plants

Contents. **1)** Introduction: history of the cultivation and uses of flaxseed, **2)** Cultivated flax and the genus *Linum* L.: Taxonomy and germplasm conservation; **3)** Chemical studies on the constituents of *Linum* spp.; **4)** Cultivation of flax; **5)** Principal diseases of flax; **6)** Principal insect pests of flax; **7)** The contribution of a-linolenic acid in flaxseed to human health; **8)** The role of flaxseed lignans in hormone-dependent and independent cancer; **9)** Flaxseed in the prevention of cardiovascular diseases; **10)** Flaxseed and flaxseed lignans: Effects on the progression and severity of renal failure; **11)** Mammalian metabolism of flax lignans; **12)** Flaxseed constituents and human health; **13)** Traditional food and medicinal uses of flaxseed; **14)** Use of flaxseed in animal diets to create consumer products with modified fatty acid profiles; **15)** Current market trends and economic importance of oilseed flax; **16)** Current regulatory status of flaxseed and commercial products; and Index.

GULSEL M. KAVALALI (eds.). 2003. ***Urtica*: Therapeutic and Nutritional Aspects of Stinging Nettles.** (ISBN 0-415-30833-X, hbk.). **Medicinal and Aromatic Plants–Industrial Profiles. Volume 37.** Series Editor: Roland Hardman. Taylor & Francis, 11 New Fetter Lane, London EC4P 4EE, UK and 29 West 35th Street, New York, NY 10001, U.S.A. (Orders: info@tandf.co.uk, www.tandf.co.uk, 44 (0) 207 583 9855, fax 44 (0) 207-842-2298, standing orders call 44 (0)1264 343071. **US and Canada Customers:** By mail: Taylor & Francis Customer Service, 10650 Toebben Drive, Independence, KY 41051, U.S.A., Toll Free Tel: 1-800-634-7064, Toll Free Fax: 1-800-248-4724, email: cserve@routledge-ny.com). $90.00, 83 pp., 1 b/w photo, tables, 7" × 10".

From Taylor & Francis website.—"This volume explores the historical and modern uses of the *Urtica* genus. An account of the botanical aspects of the genus is followed by a comprehensive review of the recent research into its biologically active constituents. With further coverage of the therapeutic uses and its nutritional value, this book presents an absorbing and all-encompassing account of the medicinal potential of *Urtica*, which will be of considerable interest to herbalists, health scientists and botanists as well as researchers in the pharmaceutical industry.

Contents.—**1)** An introduction to *Urtica* (botanical aspects); **2)** Historical and modern uses of *Urtica*; **3)** The chemical and pharmacological aspects of *Urtica*; **4)** Various therapeutic uses of *Urtica*; **5)** The therapeutic uses of *Urtica* in benign prostatic hyperplasia; **6)** Nutritional evaluation of *Urtica* species; **7)** *Urtica* products; and Index.

Traditional Herbal Medicines for Modern Times

YUKIO OGIHARA and MASAKI ABURADA (eds.). 2003. **Sho-Saiko-To: Scientific Evaluation and Clinical Applications.** (ISBN 0-415-30837-2, hbk.). **Traditional Herbal Medicines for Modern Times. Volume 4.** Series Editor: Roland Hardman. Taylor & Francis, 11 New Fetter Lane, London EC4P 4EE, UK and 29 West 35th Street, New York, NY 10001, U.S.A. (Orders: info@tandf.co.uk, www.tandf.co.uk, 44 (0) 207 583 9855, fax 44 (0) 207-842-2298, standing orders call 44 (0)1264 343071. **US and Canada Customers:** By mail: Taylor & Francis Customer Service, 10650 Toebben Drive, Independence, KY 41051, U.S.A., Toll Free Tel: 1-800-634-7064, Toll Free Fax: 1-800-248-4724, email: cserve@routledge-ny.com). $120.00, 223 pp., 81 figs. (b/w photos, graphs), tables, 7" × 10".

From Taylor & Francis website.—"Sho-Saiko-To serves as a reference for researchers and practitioners who wish to gain a scientific understanding of Sho-Saiko-To and discover how this and other Kampo medicines may be effectively integrated into Western medicine.

Contents.—**1)** Introduction; **2)** Traditional usage and therapeutic indication; **3) Crude drugs I:** taxonomical items, collection and cultivation, production etc.; **Crude drugs II:** phytochemical studies of ingredients and analytical evaluation; **Crude drugs III:** structural transformation of ingredients; **Crude drugs IV:** pharmacological and biochemical studies of medicinal plants of Sho-saiko-to; **4)** Formulation 1: quality assessment, manufacturing technology and quality control of Sho-saiko-to extract formulation; Formulation 11: pharmacokinetics, toxicology and pharmacology of Sho-saiko to; **5)** Clinical studies; **6)** Recent topics on Sho-saiko-to and other Kampo medicines; and Index.

Biographical/Bibliographical

UNIVERSITY OF TENNESSEE PRESS

CHARLES BOEWE (ed.). 2003. **Profiles of Rafinesque.** (ISBN 1-57233-225-5, hbk.). University of Tennessee Press, Suite 110, Conference Center Building, Knoxville, TN 865-974-3321, U.S.A. (Orders: fax 865-974-3724, tpost@utk.edu, www.utpress.org). $45.00, 411 pp., 45 figs., 1 color plate, 5" × 9".

As a graduate student, Charles Boewe, editor of *Profiles of Rafinesque* "developed an extracurricular curiosity about C.S. Rafinesque." After reading this book one can easily understand the fascination for this multi-faceted, multilingual, maverick. Using a number of published essays by various writers (including himself) Boewe has compiled a compelling biography of Constantin Samuel Rafinesque and at the same time sketched a picture of the state of 19th century natural science.

In his introduction, the editor discusses the difficulties of finding decisive biographical material and depends on an address given by Francis W. Pennell in 1940 to supply the framework for an authentic account of the life. This interesting essay gives an overview of Rafinesque's work in an alphabet of scientific fields with excursions into banking and manufacturing. Another writer deals with his position as a field naturalist, taxonomist, and biological theoretician in terms of modern knowledge.

Rafinesque regarded himself primarily as a traveler and nothing he encountered was beyond his purview including the study of man. He was intrigued by the American Indians he met on his journeys, studied their languages and customs and endeavored to explain the mysterious Indian

mounds he saw. His contributions to ethnology and philology and the hoax of the *Walum Olum* are the subjects of a fascinating section.

Another part of the book is concerned with Rafinesque as a writer. There is a dissection of his two-volume *Medical Flora*. Another essayist pays tribute to him as a popularizer of botany—a trend in the 19th century—with his book *School of Flora*.

The final section contains an account by John James Audubon of Rafinesque's three week visit with him in Florida where Rafinesque collected "multitudes of plants, shells, bats, and fishes." And at the last Boewe clears up the mystery of where Rafinesque is buried, but not quite.

Each of the essays is self-contained. Together they offer a splendid biography of an intriguing character. The copious notes and 45 figures add to the value of this excellent work.—*Ruth Ginsburg, Botanical Research Institute of Texas, Fort Worth, TX, 76102 4060, U.S.A.*

MARY COKER JOSLIN with drawings by SANDRA BROOKS-MATHERS. 2003. **Essays on William Chambers Coker, Passionate Botanist.** (ISBN 0-9721600-0-0, hbk.). University of North Carolina at Chapel Hill Library and the Botanical Garden Foundation, Inc. (Orders: BGF Book Sales, c/o North Carolina Botanical Garden, Totten Center CB#3375, University of North Carolina, Chapel Hill, NC 27599-3375, U.S.A., 919-962-0522). $30.00, 197 pp., b/w photos, color photos, drawings, 6" × 9 1/4".

HOWARD GARRETT. 2003. **Dear Dirt Doctor: Questions Answered the Natural Way.** (ISBN 0-292-72847-6, pbk.). University of Texas Press, P.O. Box 7819, Austin, TX 78713-7819, U.S.A. (Orders 800-252-3206 512-471-4032, 800-687-6046 fax). $16.95, 240 pp., 5 1/2" × 8 1/2".

Howard Garret, Dallas/Fort Worth's champion of gardening without toxic chemicals, has revised and updated his 1995 *Dirt Doctor's Guide to Organic Gardening* to a fast-reading, fact-filled interaction between the Dirt Doctor and his personal bounty of garden knowledge and the plant woes and wisdom of his readers and talk show listeners. From the opening chapter on the common sense and economics of gardening organically to the closing on chasing off armadillos and mice with cayenne pepper powder (it worked on one smart marauding mouse in my house!), Mr. Garrett covers soil and bed preparation, compost, synthetic vs. natural fertilizers, pest control and beneficial insects, landscaping ideas and maintenance, trees, herbs, food crops, wildflowers, turf, and indoor houseplants. The coverage is attention-grabbing, not refried generalities. For instance, on mosquitoes a reader tip relates a New Delhi research report on using peppermint oil to repel the pest and kill its larvae I sprinkled my rainwater barrels with the oil immediately. It worked. On the subject of herbs, the opening paragraph touts cinnamon oil, garlic, clovers, oregano and sage as proven destroyers of even the most dangerous strains of *E. coli*. I have used this herbal paramedic squad for eight years to keep me out of a doctor's office. They deserve opening line prominence.

A grand salute is in order to Howard Garrett for a most impressive compilation of information—with but one caveat! There are rumblings of discontent in his cornmeal paradise (see page 71). Humalfa Corporation's website, www.hu-more.com advises against the use of cornmeal with its "Green Bag" product after disturbing results form the field. There is more research to be done on its effectiveness.—*Karen M. Foley, Fort Worth, Texas.*

BOOK REVIEWS/NOTICES/BOOKS RECEIVED

Environmental/Ecology/Conservation/Landscape Ecology

GREG GORDON. 2003. **Landscape of Desire.** (ISBN 0-87421-560-9, ppk.). Utah State University Press, 7800 Old Main Hill, Logan, UT 84322-7800, U.S.A. (Orders: 435-797-1362, Fax 435-797-0313). $19.95, 213 pp. 1 map, 6" × 9".

The old professor (AKA the old philosopher) takes a group of students from the Sierra Institute for a six weeks exploration of Utah's Canyon Country. He wants each person to experience the place "on a physical level" and develop a personal awareness of the environment." To help reinvent themselves as "they metamorphose from adolescence to adulthood," everyone takes a trail name. If the reader doesn't mind accompanying Sage, Yucca, Seeker, Bobofet, Seaweed, Metta, Mud, and Huckleberry, he can learn a great deal from this book. Gordon is extremely knowledgeable about the natural history and folklore of this magnificent country and describes it in a lively manner as the group descends through the 16 geologic formations of the San Raphael/Dirty region.

Another purpose of the trip is to document the abuse of the land by motorbikes and all terrain vehicles. This leads to the examination of the whole question of the conflict between development and preservation. It's no contest. Gordon is a disciple of Leopold and Abbey.

I missed maps and pictures.—*Ruth Ginsburg, Botanical Research Institute of Texas, Fort Worth, TX, 76102-4060, U.S.A.*

VACLAV SMIL. 2002. **The Earth's Biosphere: Evolution, Dynamics, and Change.** (ISBN 0-262-19472-4, hbk.). The MIT Press, 5 Cambridge Center, Cambridge, MA 02142-1493, U.S.A. (Orders: 800-405-1619, mitpress-orders@mit.edu, http://mitpress.mit.edu). $32.95, 346 pp., 138 illustrations, 8" × 9".

Contents.—**1)** Evolution of the Idea: From Vernadsky to a Science of the Global Environment; **2)** Life in the Universe: Attributes, Constraints, and Probabilities; **3)** Life's Diversity and Resilience: Metabolisms, Species, Catastrophes; **4)** Energizing the Biosphere: Solar Radiation and the Earth's Heat; **5)** Water and Material Flows: Biospheric Cycles, **6)** The Biosphere's Extent: The Moveable Boundaries; **7)** The Biosphere's Mass and Productivity: Quantifying Life's Presence and Performance; **8)** The Biosphere's Dynamics and Organization: Fundamental Rules and Grand Patterns; **9)** Civilization and the Biosphere: The Earth Transformed by Human Action; **10)** Epilogue; Appendixes; References; Scientific Name Index; Name Index; and Subject Index.

BRIAN ALEXANDER. 2003. **Rapture: How Biotech Became the New Religion.** (ISBN 0-7382-0761-6, hbk.). Basic Books, A Member of the Perseus Books Group, 387 Park Avenue South, New York, NY 10016, U.S.A. (Orders: 212-340-8100, www.basicbooks.com). $25.95, 256 pp., 6" × 9 1/4".

Contents.—**1)** Waiting for the Rapture; **2)** The Prophet; **3)** The Endless Frontier; **4)** Arise, Lazarus Long!; **5)** The Immortal Mr. Steinberg; **6)** Way Out West; **7)** Bring On the Inquisition Water into Wine; **9)** Pop! Goes the Rapture; **10)** The Rapture Rides in a Limo; Acknowledgments; Notes; and Index.

This book basically sheds light on the modern science of cloning, stem cells, miracle drugs, and genetic engineering.

ARTHUR MOLELLA and JOYCE BEDI (eds.). 2003. **Inventing for the Environment.** (ISBN 0-262-13427-6, hbk.). The MIT Press, 5 Cambridge Center, Cambridge, MA 02142-1493, U.S.A. (Orders: 800-405-1619, mitpress-orders@mit.edu, http://mitpress.mit.edu). $29.95, 398 pp., 49 illustrations, 7" × 9 1/4".

From the dustjacket.—"This ambitious book describes the many ways in which invention affects the environment (here defined broadly to include all forms of interaction between humans and nature). The book starts with nature itself and then leads readers to examine the built environment and the specific technologies in areas such as public health and energy."

Contents.—On Nature and Technology; What Role Does Innovation Play in Urban Landscapes? How do Innovations in City Planning Shape the Environment? How Do Innovations in Architecture Affect the Environment? How can Innovations in Alternative Energy Sources Affect the Environment; How are the Principles of Industrial Ecology Applied to Benefit the Environment; Conclusion: The New Environmentalism, and Index.

PAULO S. OLIVEIRA AND ROBERT J. MARQUIS (eds.). 2002. **The Cerrados of Brazil: Ecology and Natural History of a Neotropical Savanna.** (ISBN 0-231-12043-5, hbk.). Columbia University Press, 136 South Broadway, Irvington, NY 10533-2599, U.S.A. (Orders: 800-944-1844 fax, http://www.columbia.edu/cu/cup/). $29.95, 398 pp., 49 illustrations, 7" × 9 1/4".

Contents—**1)** Introduction: Development of Research in the Cerrados; **PART I.** Historical Framework and the Abiotic Environment; **2)** Relation of Soils and Geomorphic Surfaces in the Brazilian Cerrado; **3)** Late Quaternary History and Evolution of the Cerrados as Revealed by Palynological Records; **4)** The Fire Factor; **5)** Past and Current Human Occupation and Land-Use. **PART II.** The Plant Community: Composition, Dynamics, and Life-History. **6)** Vegetation Physiognomies and Woody Flora of the Cerrado Biome; **7)** Herbaceous Plant Communities; **8)** Patterns and Dynamics of Plant Populations; **9)** The Role of Fire in Population Dynamics of Woody Plants; **10)** Ecophysiology of Woody Plants. **PART III.** The Animal Community: Diversity and Biogeography. **11)** Lepidoptera in the Cerrado Landscape and the Conservation of Vegetation, Soil, and Topographical Mosaics; **12)** The Character and Dynamics of the Cerrado Herpetofauna; **13)** The Avifauna: Ecology, Biogeography, and Behavior; **14)** The Cerrado Mammals: Diversity, Ecology, and Natural History. **PART IV.** Insect Plant Interactions. **15)** Ant Foraging on Plant Foliage: Contrasting Effects on the Behavioral Ecology of Insect Herbivores; **16)** Interactions Among Cerrado plants and Their Herbivores: Unique or typical? Robert J. Marquis; **17)** Pollination and Reproductive Biology in Cerrado Plant Communities. **PART V.** The Conservation of the Cerrados. **18)** Biodiversity and Conservation Priorities in the Cerrado Region; Index.

SARA OLDFIELD. 2002. **Rainforest.** (ISBN 0-262-15106-5, hbk.). The MIT Press, 5 Cambridge Center, Cambridge, MA 02142-1493, U.S.A. (Orders: 800-405-1619, mitpress-orders@mit.edu, http://mitpress.mit.edu). $29.95, 160 pp., 200 color illustrations, 9 1/2" × 12 1/2".

This book is a great reminder of the incredible beauty and diversity of rainforests around the world. The stunning photography is by Bruce Coleman Collection. Review forthcoming in Sida 21(1), 2004.

LOREN M. SMITH. 2003. **Playas of the Great Plains.** (ISBN 0-292-70177-2, pbk; 0-292-70534-4, hbk.). University of Texas Press, P.O. Box 7819, Austin, TX 78713-7819, U.S.A., (Orders: 800-252-3206, 800-687-6046 fax). $24.95 (pbk), $60.00 (hbk), 264 pp., 34 b/w illustrations, 6" × 9".

This book is about wetland ecology and conservation of the Playas of the High Plains. There are eight chapters broken down under three main sections; **Playas and their Environment: 1)** What is a Playa?; **2)** Origin and Development. **Ecosystem Aspects: 3)** Flora; **4)** Fauna; **5)** Structure, Function, and Diversity. **Conservation Aspects: 6)** Historical, Cultural, and Current Societal Value of Playas; **7)** Threats to Proper Function of Playas; **8)** Conservation Past, Present, and Future; Appendix; References; Index.

JAMES A. YOUNG and CHARLIE D. CLEMENTS. 2002. **Purshia: The Wild and Bitter Roses.** (ISBN 0-87417-491-0, hbk.). University of Nevada Press, Mail Stop 166, Reno, NV 89557-0076, U.S.A. (Orders: 775-784-6573 x232, 775-784-6200 fax, www.nvbooks.nevada.edu). $39.95, 280 pp., 35 b/w photos, 4 illustrations, 3 maps, 6" × 9 1/4".

The genus *Purshia* is in the family Rosaceae. The book is an indepth look at the ecology and management of habitat for these important species of plants that form a vital component of the western and intermountain vegetation. Twelve chapters discuss everything from the historical aspects of the wild and bitter roses to bitterbrush plant communities to insects and plant diseases to management issues related to *Purshia* species. The text is supplemented with line drawings and photographs.

Plant Physiology/Plant Anatomy/Pathology/Agriculture

RICHARD C. KEATING. 2003. **Anatomy of the Monocotyledons. IX Acoraceae and Araceae.** (ISBN 0-19-850122-6, hbk.). M. GREGORY and D.F. CUTLER (eds.). Oxford University Press. (Orders: Oxford University Press, 2001 Evans Road, Cary, NC 27513, U.S.A., 800-451-7556, 919-677-1303 fax, www.oup.com). $125.00, 327 pp., 855 photomicrographs in 115 plates, 7 1/2" × 9 1/2".

This is volume nine in the continuation of the series *Anatomy of the Monocotyledons*. Based upon anatomical, morphological, and molecular data, a new classification system of the Araceae is presented.

BOOK NOTICES
IOWA STATE PRESS

KRISTINA BOONE, TERRY MEISENBACH, and MARK TUCKER. 2003. **Agricultural Communications: Changes and Challenges.** (ISBN 0-8138-2167-3, pbk.). Hardback (1st) edition 2000. Iowa State Press, 2121 State Avenue, Ames, IA 50014, U.S.A. (Orders: 1-800-862-6657, 1-515-292-3348 fax; www.iowastatepress.com). $29.99, 144 pp., b/w photos and other illustrations, 6" × 9".

PETER F. FFOLLIOTT, LUIS A.BOJORQUEZ-TAPIA, and MARIANO HERNANDEZ-NARVAEZ. 2003. **Natural Resources Management Practices: A Primer.** (ISBN 0-8138-0913-4, pbk.). Hardback (1st) edition 2001. Iowa State Press, 2121 State Avenue, Ames, IA 50014, U.S.A. (Orders: 1-800-862-6657, 1-515-292-3348 fax; www.iowastatepress.com). $34.99, 256 pp., illustrations, 6" × 9".

CHARLES B. MOSS and ANDREW SCHMITZ. 2003. **Government Policy and Farmland Markets: The Maintenance of Farmer Wealth.** (ISBN 0-8138-2329-9, hbk.). Iowa State Press, 2121 State Avenue, Ames, IA 50014, U.S.A. (Orders: 1-800-862-6657, 1-515-292-3348 fax; www.iowastatepress.com). $59.99, 432 pp., tables and graphs, 6" × 9".

The book has 21 chapters that addresses farmland values and is divided into six sections: **Section I:** Historical Perspectives on Farmland Values; **Section II:** Government Policies and Farmland Values; **Section III:** Capital Markets and Farmland Values; **Section IV:** Transaction Costs and Farmland Values; **Section V:** Urbanization, Environmental Quality, and Farmland Values; **Section VI:** Regional and International Dimensions.

COLIN G. SCANES and JOHN A. MIRANOWSKI. 2004. **Perspectives in World Food and Agriculture: 2004.** (ISBN 0-8138-2021-9, hbk.). Iowa State Press, 2121 State Avenue, Ames, IA 50014, U.S.A. (Orders: 1-800-862-6657, 1-515-292-3348 fax; www.iowastatepress.com). $69.99, 485 pp., tables, graphs, drawings, 6" × 9".

Perspectives in World Food and Agriculture: 2004, written by a team of international researchers, scientists, and academics, is about global agriculture. It brings together cutting-edge agricultural research in 25 chapters, in six broad sections: **Section I:** Frontiers in World Food; **Section II:** Frontiers in Food; **Section III:** Frontiers in Animal Agriculture; **Section IV:** Frontiers in Water; **Section V:** Frontiers in Policy and Ethics; **Section VI:** Statistics and Trends in World Agriculture.

BOOK REVIEWS

DOROTHY HINSHAW PATENT. Photographs by WILLIAM MUÑOZ. 2003. **Plants on the Trail with Lewis and Clark.** (ISBN 0-618-06776-0, hbk.). Clarion Books, a Houghton Mifflin Company imprint, 215 Park Avenue South, New York, NY 10003, U.S.A. (Orders: http://www.houghtonmifflinbooks.com/catalog/titledetail.cfm?titleNumber=111018). $18.00, 112 pp., color, b/w photos, 8" × 10".

This companion to Animals on the Trail with Lewis and Clark (Clarion 2002) by Patent and Muñoz traces Lewis' and Clark's epic journey citing useful plants along the way and many of the plants they introduced to science. Though specifically written for children in grades 4 – 8, the interesting text and beautiful photographs make this book an enjoyable read for anyone wanting to know more about the importance of plants to the success of the expedition.

The book opens with a beautiful two-page map that highlights the route of the explorers from St. Louis in the midwest to Fort Clatsop on the Pacific Ocean, showing camps and landmarks along the way. Lewis and Clark took this 2000-mile route with a crew of about 40 men with orders from President Thomas Jefferson to find a navigable river passage across North America, describe, map and explore the unknown region, discuss peaceful trade with Indian tribes and investigate and record the soils, plants and animals they encountered on the journey. Patent and Muñoz do an excellent job of helping the reader understand how plants were used by members of the Expedition and Lewis,' and Clark's role in documenting these plants, many of which were new to science. The book discusses the importance of trees to the explorers' success from providing wood for the keelboat and pirogues to take the Expedition upriver, to supplying fuel for their many campfires. Patent also describes the plants used as food and medicine along the way, often citing the Indian tribe that introduced the Discovery members to various new sources of vitamins or remedies. Excerpts from Lewis' and Clark's journals throughout these chapters help the reader understand these leaders' reactions to seeing unfamiliar plants and landscapes for the first time or experiencing new plants as foods. Muñoz's striking color photographs on nearly every page spotlight examples of individual plants important to the expedition and scenic views along the trail, and they give the reader glimpses of the beautiful vistas the members of the Corps of Discovery must have witnessed on their incredible journey.

A final section discusses the fate of the specimens collected by Meriwether Lewis with color photographs of several select specimens. Patent explains Frederick Pursh's role in describing, illustrating and naming the plants collected on the expedition. Appendices include a recommended list of other books and websites regarding the Lewis and Clark Expedition, and a list of the surviving plants in the Lewis and Clark Herbarium at the Academy of Natural Sciences in Philadelphia with information on each specimen's date and location of collection.

This book provided me with a great deal of helpful information that I use in our school pro gram and teacher workshop "The Lewis and Clark Expedition Through the Eyes of Art and Science." The focus of this program is on the botanical explorations of Lewis and Clark, and I have sought many sources for background information on the specimens collected by Lewis and Clark and the importance of plants on the expedition. This book alone provided more helpful information than many sources combined.—*Amber Keller, Coordinator of School Services, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TX 76102-4060, U.S.A., akeller@brit.org.*

PAUL MARTIN BROWN. 2002. **Wild Orchids of Florida, with References to the Atlantic and Gulf Coastal Plains.** (ISBN 0-8130-2439-0, pbk.). University Press of Florida, 15 Northwest 15th St, Gainesville, FL 32611-2079, U.S.A. (Orders: www.upf.com, 800-226-3822). $24.95, 428 pp., 447 color photos, 135 b/w illus., 6" × 9".

PAUL MARTIN BROWN. 2003. **The Wild Orchids of North America, North of Mexico.** (ISBN 0-8130-2571-0, pbk.). University Press of Florida, 15 Northwest 15th St, Gainesville, FL 32611-2079, U.S.A. (Orders: www.upf.com, 800-226-3822). $27.95, 256 pp., 295 color photos, 247 b/w illus., 6" × 9".

The appeal of orchids, and books about orchids, hardly requires explanation to anyone who has ever admired or desired these plants. Even common orchids manage to maintain an air of elegant and exotic (or erotic) mystery. The name Paul Martin Brown should be well known to American orchid fanatics. He is the founder and editor of the *North American Native Orchid Journal*, and has published several previous field guides on orchids. Most recently, he was a major contributor to the Orchidaceae treatment in Volume 26 of *Flora North America*. Brown has produced two exemplary orchid field guides, for North America and for Florida, with profuse color photographs and excellent illustrations by Stan Folsom.

Wild Orchids of Florida covers 118 species and varieties, 26 growth/color forms, and 6 hybrids. Approximately half the orchid species in North America are found in Florida. The book begins with some information not typically found in field guides, including a history of orchid work in Florida, a chapter about orchids in general (morphology, habit, habitat), and a section on how to use a dichotomous key. The last is something that should definitely be included in any similar technical works with such a wide and general appeal. Following this introduction, a key to the genera of orchids in Florida is provided and supplemented with illustrations of some important couplet characters. Brief explanations are then given concerning the logic behind scientific names; the vagaries of common names; variations in size, color, and flowering time; and range map use. A map of Florida is provided, with all counties labeled.

The orchids themselves are divided into two sections: native and naturalized species, followed by introduced, escaped, or waif species. Within these sections, genera and species are in alphabetical order. Each genus is introduced by a general description and statement of range beyond Florida, and a key is given to the species, if more than one is found in the state. Each species is then treated with nearly a full page of text, listing the Latin name, common name, world range, range within Florida (frequently including status, if threatened or endangered), a description of the plant (habit, leaves, and flowers) including size ranges, habitat, and flowering period. This is followed by an entertaining paragraph containing notes of interest, which may include more information on the habitat or rarity of the species, life history, nomenclatural history, or a discussion of morphological variation within that species over a geographic range. Also on this page is a pen-and-ink illustration of the (usually) entire plant, and a Florida range map, with one dot in each county the species has been recorded. The illustrations generally depict the entire habit of the plant, including basal leaves, and are detailed enough so that most species could be identified by these drawings alone. The facing page is full of various color photos showing entire plants or populations of each species, plus close ups of inflorescences and flowers or fruits. A few poor-quality photographs do not detract from the beauty or utility of this book.

A final section entitled "Resources and References" provides a great deal of useful information, including a simple checklist of all taxa, recent literature references (listed by species), synonyms

and misapplied names, and statistics on endangered and endemic orchid species in Florida. An interesting chapter called "Orchid Hunting in Florida" divides the state into regions, and then for each region provides a discussion of habitats and a list of species. A special chapter that can be used outside of Florida, but still within the Gulf Coastal Plains of the southeastern USA, lists all extra-Floridian orchid species and their ranges. The very brief glossary will probably require supplementation from a botany text for many users of the keys. Other than this, *Wild Orchids of Florida* is a perfect field guide, with keys that will allow the identification of an orchid in-hand. Inversely, this book has enough supplementary information that a reader can probably select a (relatively common) orchid species from the book, and then go and successfully find it in the wild. Beyond these uses, the notes on each species make for entertaining armchair reading, and the photos are so enjoyable that any Floridian (and any other orchid fanciers) would be glad to own this book.

The Wild Orchids of North America covers 223 species, 24 subspecies and varieties, 103 growth/color forms, and 24 hybrids. The checklist is arranged alphabetically by genus and species. Hybrids are listed at the end of each genus. Generally, there are two species per page. Each species entry gives the Latin name and authority, synonyms and misapplied names, common name, general range, list of subspecific forms if any, references, and a brief comment about the plant's morphology, rarity, or preferred habitat. Non-native species are indicated with an asterisk next to the Latin name. Each species is illustrated with a pen-and-ink drawing and a color photograph. The photos are excellent and usually show a close-up of the flower or inflorescence. However, neither the photos nor the drawings have indications of scale, and nothing about the size of the plants or flowers is given in the species descriptions.

My main complaint about this section of the book is the layout of the text. In an effort to take up a minimum amount of page per entry, not enough space has been allowed between each element (synonyms, range, references, comment) and some lines are indented in a confusing fashion. Final comments for each species are in statement form, rather than in sentences, and begin without a capitalized first letter, causing these to visually run into the previous element in a distracting way. For many species, no references at all are given; for others, three or more are listed. The introduction's encouragement to orchid enthusiasts to seek out these plants (hopefully just for photographs) is somewhat blunted by the lack of any habitat information at all for many of the species portrayed. Following the main list of species, a shorter section contains color photos of some of the forms or hybrids already listed in the front section of the book. The next chapter contains technical keys to all the orchid genera and species in North America. The appendices include a list of excluded species, and errata for Carlyle Leur's classic works *The Native Orchids of Florida* (1972) and *The Native Orchids of the United States* (1975). The glossary is handy, but is missing some terms used in the keys, such as flabellate, pedicel, and rostellum. The term peduncle is misdefined as " the stalk of a flower or leaf," when it is in fact the stalk of an inflorescence. Following the bibliography, a personal checklist section is provided for those working on their "life list." The North American orchid book will be handy for someone who has found an orchid and would like to identify it but does not desire much more information beyond the correct name of the species. It is also an entertaining book to browse for the sake of the photographs, and could be used to familiarize oneself with the genera of North American orchids.

Both books are durably "flexibound," and the fold-out endpages have useful metric and English rulers on their margins.—*Amanda K. Neill, Botanical Research Institute of Texas, 509 Pecan St, Fort Worth, TX 76102-4060, U.S.A., aneill@brit.org.*

JENS E. MADSEN, ROBERT L. MIX, and HENRICK BALSLEV. 2001. **Flora of Puná Island: Resources on a Tropical Island.** (ISBN 87 7288 854 7, pbk.). Aarhus University Press, Langelandsgade 177, DK-8200 Aarhus N, Denmark. (Orders: www.unipress.dk, +45/89-42-53-80 fax). $39.95, 289 pp., 35 color photos, 10 b/w illus., 6 3/4" × 9 1/2".

Puná Island is situated in the Pacific Ocean near the equator, in the gulf of Guayaquil in Ecuador. Though only 3 km from the coast, the small (855 sq. km) island has a flora rich in near-endemic species. Puná Island also has an interesting cultural history of early human occupation (5000 BC), however, the island's natural vegetation has remained fairly unaltered compared to the mainland. This island contains a well-preserved remnant of tropical dry forest—an extremely endangered habitat with less than 1% remaining in the neotropics.

The text begins with an introduction to Puná Island: the geography, climate, sociology, and history of the region, including details on early exploration of the island, botanical and otherwise. The second chapter addresses the vegetation of the island, which is primarily *matorral*, or thorny deciduous forest. Seven principal plant communities are described, including mangroves, salt marshes, savannas, thorn scrubs, and dry forests, with principal plants named for each community. The thorn forest, the most widespread community on the island, is also described with quantitative structural and compositional data gathered from studies conducted in a permanent 1-hectare plot. Trees greater than 5 cm DBH (diameter at breast-height) were identified and measured. The plot was found to contain half the tree species on the entire island, with the families Bombacaceae and Bignoniaceae being most abundant. A six-year study of forest dynamics and phenology is discussed.

The third chapter summarizes the flora of Puná Island, which shows floristic similarities to the Andes and to the Galapagos Islands. This region encompasses what is known as the *Guayas center of plant endemism*—the area west of the Andes between southern Colombia and northern Peru. The native and naturalized flora of the island comprises 428 species of vascular plants; of this, 15 % of the plant species are endemic to the Guayas center. As in many floras throughout the world, the most specious families are the Fabacese, Poaceae, and Asteraceae. No species are endemic to the island itself, though rare and unusual plants are found there. Roughly 29% of the species on Puná Island are shared with the Galapagos Islands, nearly 800 km to the west. At least 14% of the species on Puná Island were introduced directly or indirectly by man and his domesticated animals. The plants used by the people on Puná Island are discussed in the fourth chapter. Archaeological evidence is given for early agricultural crops (maize, cassava, pumpkin, sweet potatoes, peppers, and cotton) as well as early tree crops (sweetsop, guava) in use in Pre-Columbian times. The early colonial period brought introductions of Old World species such as lime, melon, and sugar cane. Much detail is given concerning the use of many species for lumber in shipbuilding over the past few centuries. An ethnobotanical and linguistic study of modern plant use and plant names on Puná Island fills the rest of this chapter, with lists and discussions of edible plants, poisonous plants, useful woods, and miscellaneous uses such as dyes and soaps.

The bulk of this text is filled with keys and descriptions of all the species in the flora. This is organized by family, genus, and species. Descriptions are brief and include human uses, vernacular names, and information on nativity and distribution, as well as voucher specimen citations. Plants are not illustrated. There is no checklist as such, but there is an index in which the italicized Latin names stand out, and the description section is well-spaced and browseable. A separate index to places and historic people follows the plant index. A central section of the book groups the color photo plates of various habitats and a few plant species of ethnobotanical interest. The endpapers of the book display colored maps of Puná Island, one combining physical, political, and natural features, and one defining major plant communities. This book successfully builds upon the standard flora

format by including historical and ethnogeographical data. This book will be of interest to any who wish to learn about Pre-Columbian human occupation of coastal Ecuador, neotropical ethnobotany, and early South American agricultural practices. However, if the reader is comfortable using technical keys without illustrations, *The Flora of Puná Island* will primarily be a very useful fieldbook that can be used to identify plants anywhere in the coastal region of Ecuador.—*Amanda K. Neill, Botanical Research Institute of Texas, 509 Pecan St, Fort Worth, TX 76102-4060, U.S.A., aneill@brit.org.*

BERTIL NORDENSTAM, GAMAL EL-GHAZALY, and MOHAMED KASSAS (eds). 2000. **Plant Systematics for the 21st Century: Proceedings from a symposium held at the Wenner-Gren Centre, Stockholm, in September 1998.** (ISBN 1-85578-135-2, hbk.). Wenner-Green International Series, Vol. 77. Portland Press Ltd., 59 Portland Place, London W1B 1QW, U.K. (Orders: +44-020-7580-5530, editorial@portlandpress.com, North American orders to: Princeton Univ. Press, 41 William St. Princeton, NJ 08540, U.S.A.). $120.00, 376 pp., numerous b&w drawings, charts, and halftones, 6 3/4" × 9 1/2".

The august title, "Plant systematics for the 21st century," may capture many purchasers for this book. If so, the readers will be soundly disappointed with their acquisition. This is not to say there are not many useful and insightful contributions; there are. But taken together, these collected papers do not fulfill the promise of the title.

In actuality, this is a festschrift for two prominent and influential Swedish botanists, Vivi Laurent-Täckholm and Gunnar Edrtman, who would have been 100 years old at the time of the symposium. Notice the more accurate characterization found in the introduction:

"In choosing the themes of the symposium we planned to give an overview of the fields of these two scholars, namely plant systematics and palynology. In addition to commemorating and remembering the contributions of Täckholm and Erdtman, we also wished to summarize current knowledge in these fields. We also aimed to include new information on some related and expanding research areas of great biological interest and significance, such as aspects of anatomy and floral odours."

Five papers are biographical. As commemorations of the contributions of Erdtman and Täckholm, respectively, six papers discuss advances in palynology, while four summarize recent studies in the flora of Egypt. Six more papers deal with current issues in plant systematics including limits to computer analysis and nomenclatural challenges. Four papers examine new techniques that have been applied to problems in particular families or orders. Finally the last paper records the panel discussion used to wrap up the symposium.

Many of the biological papers are case studies of the application of new methods to plant systematics, even the overview papers. A good example is Prance's paper on the changing focus of research on the Chrysobalanaceae over the last 40 years. Even Källersjö and Farris' paper serves primarily to highlight the contribution of Farris' computer algorithm on parsimony jackknifing. Probably the best overviews of research advances are El-Ghazaly's paper on new methods in palynology, Ferguson's paper on application of pollen morphology in systematics, and Chanda's comments on the application of palynology to understanding related fields.

While all the biological papers are excellent summaries of new methods and application of those methods over the closing decades of the 20th century, only two are truly forward looking. Kubitzki's contribution reviews the state of plant systematics. He tries to foresee the future trends in cladistic and molecular analysis, conflicting data, and information technology. Greuter is concerned for the future of plant nomenclature and the challenge to provide stable names for species and higher taxa as global conservation becomes an increasingly important goal for biologists.

The panel discussion disappoints one looking for the future prospects of plant systematics. It comes as no surprise that nearly all the speakers agreed that the top three priorities should be 1) documentation of the world's biodiversity before it is irreversibly lost, 2) conservation of that biodiversity, and 3) continued research to better understand evolutionary mechanisms. Some of the speakers mentioned increasing and improving herbarium and biological databases and retrieval. However, no room was given to developing models on how the greatly expanded databasing should be achieved. Indeed the only other reference to this important issue was a couple of paragraphs in Kubitzki's paper.

Surprisingly, I found very little on the next phase for molecular biology. That is, moving from a simplistic comparisons of nucleotide sequences in a few analyzable genes to understanding the underlying genetics of integrated character complexes of expressed phenotypes. Indeed, in Kubitzki's assessment I found just the opposite, "To this end [of interpreting character evolution] morphological or other traits can be mapped onto cladograms, which should preferably be based on molecular data." While I understand his concern of avoiding circular reasoning by using alternate data sets, I see a problematic attitude that is developing in systematics, even among the traditional morphologically oriented researchers. Are we (as a biosystematics community) to form our classifications on one or a few genes and force the interpretation of morphological characters, many of which derive from highly correlated multi-gene complexes, onto those simple gene trees? Are we falling headlong again into the trap of "one character taxonomy?" Perhaps we should be more prudent, realizing that these highly sophisticated, but philosophically simplistic methods are not showing us phylogenetic history any more than do the confusingly homoplastic morphological methods.

While this book falls short of its purported goal, nonetheless it is a valuable collection of articles. It is worth owning, especially for accessing the literature on palynology, Egyptian botany, nomenclature, and various modern systematic techniques.—*Roger W. Sanders, Associate Collections Manager, Botanical Research Institute of Texas, 509 Pecan St, Fort Worth, TX 76102-4060, U.S.A., rsanders@brit.org.*

MARK BONTA. 2003. **Seven Names for the Bellbird: Conservation Geography in Honduras.** (ISBN 1-58544-249-6, hbk.). Texas A&M University Press, John H. Lindsey Bldg., Lewis St., 4354 TAMU, College Station, TX 77843-4354, U.S.A. (Orders: 1800-826-8911, w-lawrence@tamu.edu, www.tamu.edu/upress). $35.00, 250 pp., 35 b&w photos, 4 maps, 5 3/4" × 9 1/4".

Within the text, Mark Bonta takes an ethnographic approach to understanding the relationship between the local people of Honduras and the birds of their region, thus serving to create a bridge between academic geography and what he calls "on-the-ground conservation." The recounting of this approach and its results takes the form of individual and family histories and stories relayed throughout the text. The particular intent of the text is to dissuade the reader that humans are entirely destructive with a conscious purpose, and that in particular the relationship between Honduran locals and their avifauna is not inherently detrimental to the birds. However, Bonta does not parade his findings as assurance that the birds have a secure place in the Neotropical landscape.

The text is divided into nine separate chapters, preceded by an introduction to conservation geography, as it will be dealt with for the remainder of the text, and succeeded by an appendix listing the birds recorded for the central Olancho department of Honduras as well as a glossary of Spanish terms. The first chapter delves into the subject of "ornithophilia" (a natural love for birds) through the depiction of a young girl, Lucita, and her interaction with the birds in her area. As a standard for

chapters dealing with personal histories, Bonta further divides each into sections, the first few serving as stand-alone examples of what in the latter sections he takes apart and reflects on in his own voice.

Chapter two establishes the geographical and historical background of the region and its bird population, acknowledging these features as among the most important contributors to the varying relationships with birds. Chapter three takes into account that Honduras is a male-dominated society and the more obvious facets of relationships with birds are not the only ones; women and children are given voices to share their perceptions of the issue. Chapter four lays bare the situation within Juticalpa, an urban center in Olancho, using case studies of two birds, the *zopilote* (Black Vulture) and the *zorzal* (Clay-colored Robin). Chapter five brings up the capacity in which large landowners act as conservationists, contrary to general expectation. Chapter six presents the other side of chapter four, highlighting the rural landscape of small domestic and individual villages and farmers, where biodiversity is highest and may be most easily conserved. Chapter seven exposes Honduras as a country where the majority of soil cover is not rainforest, and where many species requiring the attention of conservationists do not make their homes in virgin rainforest. Other marginalized species are also dealt with, such as those that are nocturnal. Chapter eight is a case study centered about the montane rainforest of Montaña de Babilonia. In chapter nine Bonta presents several proposals regarding the conservation geography of Honduran avifauna, with the intent for broader applications.

Perhaps the message which Bonta intends be taken home is that the destruction in the Neotropics is not accomplished with clear and purposeful intent, but rather as a side effect of certain socio-economic factors. Therefore, to lessen its impact, we must take a "geographical approach to conservation that cuts across artificial boundaries separating what is 'natural' from what is 'cultural' in the landscape" (p.3). While the theme of conservation geography is implied throughout the book, it is only in the last chapter where it is dealt with directly, and where it ceases to merely be an "ethnography of birds." The book does not resort to scientific and technical terms and therefore is easily understood; it is for a general audience interested in avifauna, conservation, and the idea of a "cultural landscape."—*Tiana Franklin, Botanical Research Institute of Texas, 509 Pecan St, Fort Worth, TX 76102-4060, U.S.A., tfranklin@brit.org.*

PAUL E. MINNIS (Ed.). 2003. **People and Plants in Ancient Eastern North America.** (ISBN 1-58834-133-X, pbk.). Smithsonian Institution Press, 750 Ninth Street NW, Suite 4300, Washington, DC 20560-0950, U.S.A. (Orders: 202-275-2300, http://www.sipress.si.edu/). $34.95, 423 pp., 25 figs., 45 tables, 6" × 9".

This text is presented as the first in a two-volume set, consisting of eight chapters by contributing North American anthropologists. Minnis chooses to extend the time frame of ethnobotany to the past, and therefore deal with methods of paleoethnobotany. Using these methods, the contributing authors delve into three subject areas: prehistoric use of plants, crop history and applications, and human impacts on local environments. This first volume is loosely contained by geographical boundaries into, as the title indicates, an overview of Eastern North America; its fellow, as yet unpublished, will cover the remaining Western North American region.

In a sixteen-page introduction, Minnis provides an historical overview of the field of paleoethnobotany, quite easily explained for those of us that may have little use for such long-strung terms. Following this are chapters that concentrate on the Central and Southern Woodlands (about which much work has been done in the past), native plant use, crop domestication and food production, anthropogenic ecology, and regional concentrations in the Northeast, the Great Plains, and in the Caribbean Islands.

While it may be implied that the only data set for the conclusions drawn in the text consists of micro- and macro-botanical remains, this is not entirely the case. In the foreword, Minnis clearly establishes that along with botanical remains, such things as ancient field distribution and plant images in art can be used to infer ancient ethnobotanical relationships. The contributing authors present their portions particularly well although, having worked with botanists but not belonging to the discipline themselves, tend to generalize and lump various evidences unto one name, whereas in botanical nomenclature, 'fruit' would be inadequate and demand further explanation.

This compilation reads surprisingly well and holds interesting and significant information for the concerned environmentally-minded reader, bringing attention to issues such as the fact that the majority of human food supply is derived from a play of only 20 crops, whereas paleoethnobotanical evidence uncovers a suite of tens of thousands of crops cultivated in the past.—*Tiana Franklin, Botanical Research Institute of Texas, 509 Pecan St, Fort Worth, TX 76102-4060, U.S.A., tfranklin@brit.org.*

BIENNIAL REPORT AND UPDATE 2002–2003

SIDA, CONTRIBUTIONS TO BOTANY

Source of current research in classical and modern *systematic botany for readers throughout the world.*

...bringing out the best in botanical science for plant conservation and education.

To all authors, we thank you for choosing *Sida, Contributions to Botany* as your forum to disseminate information and knowledge gained by scientific inquiry. Volume 20 represents the largest volume of SIDA ever published. SIDA is published twice a year with each issue seemingly increasing in size and in diversity of quality papers. Volume 20 has 1836 pages, 202 authors, 165 published contributions, and includes 229 new names and new combinations. Published papers are available online in Adobe Acrobat format (PDF files); the PDF files are true representations of the hard copy of SIDA. <*http://www.brit.org/sida/SCBCurIssue.htm*>.

A word of thanks to the 228 individuals acknowledged on pages 1793–1794, who generously supported SIDA through their time and expertise in reviewing approximately 188 manuscripts submitted for volume 20. All manuscript submissions are peer-reviewed by distinguished reviewers; your support is deeply appreciated. If by chance you reviewed a manuscript and your name was left out, the error rests solely on the shoulders of this editor and I truly apologize. Please bring any omissions to my attention.

Below are the dates of publication for each of the four issues of volume 20, subscriptions for calendar year 2004, and distribution of SIDA. We also bring to your attention (see page 1792) the *Mary M. Hennen Scientific Publications Endowment*, established to provide support to the future of BRIT's scientific publication program (*Sida, Contributions to Botany* and *Sida, Botanical Miscellany*). The index to volume 20 (2002–2003) follows and the issue concludes with a printed copy of the current guidelines to contributors. The online version is at *http://www.brit.org/sida/SubmitPaper.htm*.

We thank all authors, reviewers, subscribers (individuals, institutions, organizations), and readers for your continued interest and support. It is our plan to continue bringing you the best sources of current research in classical and modern systematics with your continued support. Wishing you the best in 2004 and beyond.—**Barney Lipscomb** (BRIT), Editor; **John W. Thieret** (NKU), Associate Editor; and **Félix Llamas** (LEB), Contributing Spanish Editor.

Dates of publication

20(1), pp. 1–460: 19 July 2002
20(2), pp. 461–876: 23 November 2002 (40-year anniversary issue)
20(3), pp. 877–1341: 29 July 2003
20(4), pp. 1343–1836: 22 December 2003

Subscriptions and distribution.—SIDA is distributed in over 90 countries. There are 900 subscriptions, 377 domestic and 523 foreign. Brazil has the most subscribers (39) outside of the U.S.A. SIDA is available either through paid subscription or scholarly exchange. Online information is available at *http://www.brit.org/sida/subscription.htm.*

Annual subscription rates for *Sida, Contributions to Botany* for 2004.

Domestic (USA only)

1)Subscribing institutions (universities, libraries, and other institutes including agents)**$60.00**

2)Individual personal subscriptions**$35.00**

Outside the USA

1)Subscribing institutions (universities, libraries, and other institutes including agents)**$70.00**

2)Individual personal subscriptions**$35.00**

Mary M. Hennen Scientific Publications Endowment Established.—In honor of his wife, **Mary**, BRIT research associate, professor emeritus of botany at Purdue University, the world's pre-eminent authority on the systematics and biogeography of the rust fungi, **Joe Hennen** has established the *Mary M. Hennen Scientific Publications Endowment* to provide support to the future of BRIT's scientific publication program (*Sida, Contributions to Botany* and *Sida, Botanical Miscellany*). Joe and Mary (life-science librarian at Purdue University) have long recognized that publication of scientific botanical information is an integral part of conserving our natural heritage.

Every gift will make a difference for the future of *Sida* and *Sida, Bot. Misc.* There are many different ways to make a gift; use a credit card, give a check, stock, pledge, bequest, trust, memorials, employer/employee matching contributions, installments, etc. The BRIT Press seeks your support to ensure innovation and excellence in preparation, manufacture, and distribution of botanical research and scientific discoveries for the twenty-first century. For more information about the BRIT Press or anyone interested in making a contribution to the *Mary M. Hennen Scientific Publications Endowment*—which supports *Sida* and *Sida, Bot. Misc.*—contact **Barney Lipscomb** at the Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, Texas 76102-4060, USA; 817-332-7432; barney@brit.org; sida@brit.org.

Reviewers: Volume 20 (2002-2003)

SIDA 20(4): 1794. 2003

INDEX TO 165 TITLES WITH 202 AUTHORS: VOLUME 20 (2002–2003)

We know you have a choice. Thank you for choosing *Sida, Contributions to Botany.*

A community-level floristic reconnaissance of the Raja Ampat Islands in New Guinea by W. TAKEUCHI—**20(3):**1093

A cypress (**Cupressus arizonica**, Cupressaceae) in Jeff Davis County, Texas? by M. PATRICK GRIFFITH and STEPHANIE C. BARTEL—**20(2):**585

A floristic survey of Big Branch Marsh National Wildlife Refuge, St. Tammany Parish, Louisiana by DAVID J. ROSEN and STANLEY D. JONES—**20(3):**1189

A new section of **Baccharis** (Asteraceae: Astereae), and notes on allied taxa by DANIEL A. GIULIANO and GUY L. NESOM—**20(4):**1481

A new species of **Arida** (**Machaeranthera** sect. **Arida**—Asteraceae: Astereae) from Trans-Pecos, Texas by B.L. TURNER and GUY L. NESOM—**20(4):**1417

A new species of **Brazoria** (Lamiaceae) from the central mineral region of Texas by MATT W. TURNER—**20(4):**1565

A new species of **Chaptalia** (Asteraceae: Mutiseae) from Mexico and rediscovery of **Chaptalia mexicana** by LETICIA CABRERA R. and GUY L. NESOM—**20(4):**1363

A new species of **Dioscorea** (Dioscoreaceae) from the Andes of Venezuela by L.J. DORR and BASIL STERGIOS—**20(3):**1007

A new species of **Eriogonum** (Polygonaceae) from south Texas by GUY L. NESOM – **20(1):**31

A new species of **Gonolobus** (Apocynaceae: Asclepiadeae, Gonolobinae) from southern Costa Rica by ALEXANDER KRINGS —**20(1):**105

A new species of **Lithospermum** (Boraginaceae) from Nuevo León, México by B.L. TURNER—**20(2):**501

A new species of **Medinilla** (Melastomataceae) from Anamalai Hills, South India by N. SASIDHARAN and P. SUJANAPAL—**20(1):**109

A new species of **Packera** (Asteraceae: Senecioneae) from the Edwards Plateau of Texas by DEBRA K. TROCK and ROBERT J. O'KENNON—**20(3):**945

A new species of **Schistocarpha** (Asteraceae: Heliantheae) from northwestern Oaxaca and closely adjacent Guerrero, México by B.L. TURNER—**20(2):**505

A new species of **Senecio** (Asteraceae) from Durango, Mexico by B.L. TURNER—**20(1):**175

A new species of **Solidago** (Asteraceae: Astereae) from north central Alabama by BRIAN R. KEENER and ROBERT KRAL—**20(4):**1589

A new species of **Stylogyne** (Myrsinaceae) from Darién, Panama by JON M. RICKETSON and JOHN J. PIPOLY III—**20(3):**919

A new variety of **Ipomoea costellata** (Convolvulaceae) from the Edwards Plateau region of Texas by ROBERT J. O'KENNON and GUY L. NESOM—**20(1):**39

A revision of the **Psidium salutare** complex (Myrtaceae) by LESLIE R. LANDRUM—**20(4):**1449

A rockhouse microhabitat in the West Cross Timbers of North Central Texas by GEORGE M. DIGGS, JR. and ROBERT J. O'KENNON —**20(3):**1327

A significant new population of the rare semaphore pricklypear cactus, **Opuntia corallicola** (Cactaceae) by Keith A. Bradley and Steven W. Woodmansee—**20(2):**809

A synopsis and nomenclator of the genus **Parathesis** (Myrsinaceae) by Jon M. Ricketson and John J. Pipoly III—**20(3):**913

A synopsis of **Machaeranthera** (Asteraceae: Astereae), with recognition of segregate genera by David R. Morgan and Ronald L. Hartman—**20(4):**1387

Addition to Flora Mesoamericana: a new record of **Thelypteris** (Thelypteridaceae) for Chiapas, Mexico by Miguel A. Pérez Farrera, Ramón Riba, and María E. López-Molina—**20(3):**1311

Additions to the Cyperaceae and Juncaceae flora of the Río Mayo region, Sonora, Mexico by Eric H. Roalson, Thomas R. Van Devender, and Ana Lilia Reina G.—**20(1):**339

Additions to the flora of Cleveland County, Arkansas: collections from Moro Bottoms Natural Area, a state-protected old-growth bottomland hardwood forest by Danny Skojac, Margaret S. Devall, and Bernard R. Parresol—**20(4):**1731

Additions to the flora of Nags Head Woods (Dare County, North Carolina) and the outer banks of North Carolina by Alexander Krings—**20(2):**839

Agave ovatifolia (Agavaceae), una nueva especie de maguey del noreste de México by Greg Starr and José A. Villarreal Q.—**20(2):**495

Agrostis avenacea (Poaceae: Pooideae): first record for the Mexican flora by Arely Nava-Rojo, Maricela Gómez-Sánchez, and Manuel González-Ledesma—**20(1):**423

An update to the vascular flora of Calcasieu Parish, Louisiana by Ray Neyland—**20(1):**431

Anatomía comparada de la epidermis foliar en el grupo de especies **Solanum sessile**, de la sección **Geminata** (Solanaceae) by Carmen Benítez de Rojas and Chiara Berlingieri—**20(4):**1651

Andropogon glomeratus var. **glaucopsis** (Poaceae: Andropogoneae) documented in Louisiana by David J. Rosen and Joseph K. Wipff—**20(4):**1723

Annotated checklist of the vascular flora of the Hickory Creek Unit of the Big Thicket National Preserve, Tyler County, Texas by Barbara R. MacRoberts, Michael H. MacRoberts, and Larry E. Brown—**20(2):**781

Another juniper (Cupressaceae) in Jeff Davis County Texas? We're not convinced by John P. Karges and James C. Zech—**20(3):**1325

Arkansas flora: additions, reinstatements, exclusions, and re-exclusions by James H. Peck—**20(4):**1737

Aspectos ecológicos y estado de conservación de **Mammillaria theresae** (Cactaceae) by Irma Lorena López-Enríquez, M. Socorro González-Elizondo, Martha González-Elizondo, and Jorge Alberto Tena-Flores—**20(4):**1665

Biological status of **Hedyotis nigricans** var. **gypsophila** (Rubiaceae) in Texas by B.L. Turner—**20(1):**215

Biosystematic analysis of the **Thelesperma subnudum** complex (Asteraceae) by Curtis J. Hansen, Loreen Allphin, and Michael D. Windham—**20(1):**71

Boerhavia coulteri var. **palmeri**, a new varietal combination for **Boerhavia** (Nyctaginaceae) of southwestern North

America by RICHARD SPELLENBERG—**20(1):**151

Botanical summary of a lowland ultrabasic flora in Papua New Guinea by W. TAKEUCHI—**20(4):**1491

Carex conoidea (Cyperaceae) new to Arkansas and notes on its occurrence in Arkansas and Missouri by PAUL M. MCKENZIE, TIM SMITH, and C. THEO WITSELL —**20(4):**1727

Carlo Bertero (1789 -1831) in the New World by PIERO G. DELPRETE, GIULIANA FORNERIS, and ANNALAURA PISTARINO—**20(2):**621

Castilleja albobarbata sp. nov. (Orobanchaceae) from Sierras Manantlán and Cacoma, Jalisco, Mexico by HUGH H. ILTIS, GUY L. NESOM, and J. MARK EGGER—**20(4):**1343

Celebration honors pioneer field botanist André Michaux by WILLIAM R. BJRK—**20(2):**861

Cirsium nuttallii (Asteraceae: Cynareae) new to North Carolina and an illustrated key to southeastern congeners by ALEXANDER KRINGS, RANDY WESTBROOKS, and JANINE LLOYD —**20(2):**845

Commelina benghalensis (Commelinaceae) new to North Carolina and an updated key to Carolina congeners by ALEXANDER KRINGS, MICHAEL G. BURTON, and ALAN C. YORK—**20(1):**419

Comparison of the morphology, flowering phenology, and life cycle type in plants of **Grindelia lanceolata** (Asteraceae) from cedar glades in middle Tennessee and northern Alabama: a common garden study by CHRISTOPHER A. ADAMS, JERRY M. BASKIN, and CAROL C. BASKIN—**20(3):**1059

Cryptocoryne beckettii complex (Araceae) introduced at a Florida spring by COLETTE C. JACONO—**20(2):**819

Cynosurus echinatus (Poaceae) new to Texas by R. DALE THOMAS—**20(2):**837

Dahlia neglecta (Asteraceae: Coreopsideae), a new species from Sierra Madre Oriental, México by DAYLE E. SAAR—**20(2):**593

Del Weniger (1923–1999), remarkable teacher and naturalist by MARJORIE FOHN EPLER—**20(2):**867

Documented chromosome numbers 2002: 1. Chromosome number of **Stenanthium** (Liliales: Melanthiaceae) and its significance in the taxonomy of tribe Melanthieae by WENDY B. ZOMLEFER and GERALD L. SMITH—**20(1):**221

Documented chromosome numbers 2002: 2. Chromosome numbers in North American species of **Cerastium** (Caryophyllaceae) by J.K. MORTON—**20(1):**227

Documented chromosome numbers 2002: 3. Chromosome counts for **Packera paupercula** var. **appalachiana** (Asteraceae: Senecioneae) by ALISON MCKENZIE MAHONEY, VIRGINIA W. KONG, and ROBERT R. KOWAL—**20(2):**605

Documented chromosome numbers 2003: 1. Chromosome number of **Toxicoscordion nuttallii** (Liliales: Melanthiaceae) and clarification of the genus by WENDY B. ZOMLEFER—**20(3):**1085

Documented chromosome numbers. 2003: 2. Chromosome numbers of the rare Texas species, **Arida blepharophylla** and **A. mattturneri** (Asteraceae: Astereae) by A. MICHAEL POWELL—**20(4):**1663

Does **Polygonum patulum** (Polygonaceae) grow in North America? by MIHAI COSTEA and FRANÇOIS J. TARDIF—**20(4):**1707

Effects of fire on two pitcher plant bogs with comments on several rare and interesting plants by Eric L. Keith and N. Ross Carrie—**20(1):**387

Endemism in the West Gulf Coastal Plain: importance of xeric habitats by Michael H. MacRoberts, Barbara R. MacRoberts, Bruce A. Sorrie, and Robert E. Evans—**20(2):**767

Erratum—**20(1):**445

Euchiton (Asteraceae: Gnaphalieae) in North America and Hawaii by Guy L. Nesom—**20(2):**515

Fagopyrum esculentum (Polygonaceae), new for Texas by Robert J. O'Kennon, Caren McLemore, and Amanda K. Neill—**20(4):**1717

Festuca dentiflora (Poaceae:Loliinae:sect. **Glabricarpae**), a new species from Peru and taxonomic status of **F. presliana** by Daniel Stančík and Paul M. Peterson—**20(3):**1015

Flora and vegetation of the Mohawk Dunes, Arizona by Richard Stephen Felger, Dale Scott Turner, and Michael F. Wilson—**20(3):**1155

Floristics of xeric sandylands in the post oak savanna region of East Texas by Barbara R. MacRoberts, Michael H. MacRoberts, and James C. Cathey—**20(1):**373

Further additions to the genus **Ardisia** subgenus **Graphardisia** (Myrsinaceae) by Jon M. Ricketson and John J. Pipoly III—**20(4):**1423

Glandularia verecunda (Verbenaceae): species or fruit-form? by B.L. Turner—**20(4):**1647

In memoriam: Chester Morrison Rowell, Jr., (1925–2003) by Jim Blassingame—**20(4):**1771

Ipomoea tacambarensis (Convolvulaceae), especie nueva del estado de Michoacán, México by Eleazar Carranza González—**20(4):**1351

Key to the species of Ericaceae of Bolivia, including two new species by James L. Luteyn—**20(1):**1

Koenigia islandica (Polygonaceae) new for Utah by Mihai Costea and François J. Tardif—**20(3):**1319

Lectotypification of **Mentzelia texana** and **M. lindheimeri** (Loasaceae) with an assessment of their biological status by Billie L. Turner—**20(1):**157

Lectotypification of **Pseudognaphalium biolettii** (Gnaphalieae: Asteraceae) by Guy L. Nesom—**20(1):**149

Lectotypification of Schlechtendal Myrsinaceae from Schiede and Deppe collections by Jon M. Ricketson and John J. Pipoly III—**20(3):**909

Liatris gholsonii (Asteraceae: Eupatorieae), a new blazing star from the Apalachicola River bluffs and ravines in Florida by Loran C. Anderson—**20(1):**97

Listado preliminar de las Cactáceas y Agavaceas de la Sierra "El Viejo," Sonora, región prioritaria para la conservación en México by Carlos G. Velazco Macías and Glafiro J. Alanís Flores—**20(1):**349

Muhlenbergia dubia (Poaceae) in central Texas by Geoffrey C. Denny—**20(4):**1763

Native flowering plant species new or otherwise significant in Kentucky by Robert F.C. Naczi, Ronald L. Jones, F. Joseph Metzmeier, Mark A. Gorton, and Timothy J. Weckman—**20(1):**397

Nephrolepis exaltata (Dryopteridaceae) new to Arkansas by James H. Peck—**20(2):**833

New and noteworthy orchids of the Bis-

marck Archipelago, Papua New Guinea by N.H.S. Howcroft and W. Takeuchi—**20(2):**461
New combination in Astereae (Asteraceae) by Guy L. Nesom and Harold Robinson—**20(4):**1649
New combination in **Eurybia** (Asteraceae: Astereae) from North America by Luc Brouillet—**20(4):**1561
New combination in **Salix** (Salicaceae) by Guy L. Nesom—**20(2):**523
New combination in **Xylorhiza** (Asteraceae: Astereae) by Guy L. Nesom—**20(1):**145
New names and combinations in goldenrods, **Solidago** (Asteraceae: Astereae) by John C. Semple—**20(4):**1605
New names and new combinations in the flora of Hispaniola by Henri Alain Liogier—**20(4):**1645
New records in Asteraceae for Alabama and Arkansas by Guy L. Nesom—**20(1):**403
New records of **Corchorus** (Tiliaceae) for Mexico by José Aurelio Colmenero Robles and Rafael Fernández Nava—**20(3):**1299
New taxa of **Crataegus** (Rosaceae) from the northern Okanagan–southwestern Shuswap diversity center by J.B. Phipps and R.J. O'Kennon—**20(1):**115
New vascular plant records for Texas by Guy L. Nesom and Robert J. O'Kennon—**20(1):**435
New vascular plant records for the grassland biome of central North America by Craig C. Freeman, Caleb A. Morse, and Ronald L. McGregor—**20(3):**1289
Nomenclatural adjustments and comments in **Abronia** and **Acleisanthes** (Nyctaginaceae) by Richard Spellenberg and Jackie M. Poole—**20(3):**885
Nomenclatural changes and innovations in **Panicum** and **Dichanthelium** (Poaceae: Paniceae) by Robert W. Freckmann and Michel G. Lelong—**20(1):**161
Nomenclatural changes in the genus **Polygonum** section **Polygonum** (Polygonaceae) by Mihai Costea and François J. Tardif—**20(3):**987
Nomenclatural combinations in North American **Panicum** subgenus **Dichanthelium** and subgenus **Agrostoides** (Poaceae: Paniceae) by Joseph K. Wipff—**20(3):**1043
Nomenclature of the heart-leaved hedge-nettle, **Stachys cordata** (Lamiaceae) by James S. Pringle—**20(2):**583
Northward range extension in Florida of the invasive fern **Lygodium microphyllum** (Lygodiaceae) by Robert W. Pemberton—**20(4):**1759
Norwegian and Sámi ethnobotany of **Veratrum album** (Melanthiaceae) by Torbjørn Alm—**20(2):**611
Notes on **Carphephorus odoratissimus** (Asteraceae) in peninsular Florida, U.S.A. by Steve L. Orzell and Edwin L. Bridges—**20(2):**559
Notes on the flora of Texas with additions and other significant records. II by Larry E. Brown and I. Sandra Elsik—**20(1):**437
Notes on two species of **Agalinis** (Scrophulariaceae) including **Agalinis harperi**, new to Texas by Eric L. Keith and John Hays—**20(3):**1321
Noteworthy vascular plants from Arkansas. II by Eric Sundell, R. Dale Thomas, Carl Amason, and Chris Doffitt—**20(1):**409

On the derivation of the generic name **Iliamna** (Malvaceae) by William A. Weber and Paul A. Fryxell—**20(2):**645

Oxypolis ternata (Apiaceae) deleted from the Texas flora by Bruce A. Sorrie, Michael H. MacRoberts, Barbara R. MacRoberts, and Suzanne Birmingham Walker—**20(3):**1323

Pappus variation in **Solidago** (Asteraceae: Astereae) by Jennifer L.A. Hood and John C. Semple—**20(4):**1617

Perforation plate diversity in **Illicium floridanum** (Illiciaceae) with respect to organs, provenance, and microtechnical methods by Edward L. Schneider and Sherwin Carlquist—**20(3):**1047

Plants new to the United States and Florida by Richard P. Wunderlin, Bruce F. Hansen, and Loran C. Anderson—**20(2):**813

Polygonum aviculare subsp. **rurivagum** (Polygonaceae) in North America by Mihai Costea and François J. Tardif—**20(4):**1709

Polygonum douglasii subsp. **johnstonii** (Polygonaceae) new for Canada by Mihai Costea and François J. Tardif—**20(3):**1317

Portulaca matthewsii (Portulacaceae), a new species from the "Sierra Gorda" Biosphere Reserve, Querétaro, Mexico by Gilberto Ocampo Acosta—**20(4):**1357

Pteroceras monsooniae (Orchidaceae), a new species from India by N. Sasidharan and P. Sujanapal **20(3):**923

Rediscovery of **Tephrosia jamnagarensis** (Fabaceae), an endangered and narrow endemic plant species of Saurashtra, Gujarat, India by P.S. Nagar, S.J. Sata, and S.J. Pathak—**20(4):**1701

Reinstatement of **Viburnum ozarkense** (Caprifoliaceae): an endemic taxon of the Interior Highlands of Arkansas, Missouri and Oklahoma by Timothy J. Weckman—**20(2):**849

Resource allocation patterns and phenotypic variation in the endangered Texas wildrice (**Zizania texana**, Poaceae) by Paula Power—**20(2):**571

Revision and typification of some species of **Ixora** (Rubiaceae) from Central and Southern Brazil by Piero G. Delprete—**20(4):**1471

Rotala rotundifolia (Lythraceae) new to Florida by Kathleen C. Burks, Vernon V. Vandiver, Jr., David W. Hall, and Colette C. Jacono—**20(4):**1765

Rupert Barneby Award—**20(1):**446

Rust fungi (Uredinales) of Northwest Argentina by José R. Hernández and Joe F. Hennen—**20(1):**313

Seed and fruit characters in selected Spermacoceae and comparison with Hedyotideae (Rubiaceae) by Edward E. Terrell and Richard P. Wunderlin—**20(2):**549

Senecio spribillei (Asteraceae: Senecioneae), a new species from Montana, U.S.A. by William A. Weber—**20(2):**511

Sinopsis del género **Meliosma** (Sabiaceae) en Costa Rica y Panamá, con tres nuevas especies by J. Francisco Morales—**20(3):**931

Six non-native species newly discovered in the Iowa vascular flora by Allison W. Cusick—**20(1):**405

Soil-dependent fire frequency: a new hypothesis for the distribution of prairies and oak woodlands/savannas in North Central and East Texas by George M. Diggs, Jr. and Peter C. Schulze—**20(3):**1139

Solidago faucibus (Asteraceae: Astereae),

a new mesic forest goldenrod from the Appalachian Mountains by THOMAS F. WIEBOLDT and JOHN C. SEMPLE—**20(4):**1595

Sphaeralcea caespitosa var. **williamsiae**, var. nov. (Malvaceae) by NOEL H. HOLMGREN —**20(1):**47

Studies in **Glandularia** (Verbenaceae): the **Glandularia quadrangulata** complex by JAMES HENRICKSON—**20(3):**953

Symplocos kothayarensis (Symplocaceae), a new species from peninsular India by V. SUNDARESAN, S. RAJKUMAR, G.J. JOTHI, and V.S. MANICKAM—**20(3):**927

Taxodiomeria (Taxodiaceae), an intergeneric hybrid between **Taxodium** and **Cryptomeria** from Shanghai, People's Republic of China by ZHANG JIAN-JUN, PAN SHI-HUA, ZHU WEI-JIE, NIU HUI-JUAN, YE ZHENG-JI, ZHU JIAN-HUA, and HSU PING-SHENG—**20(3):**999

Taxonomy of the most common weedy European **Echinochloa** species (Poaceae: Panicoideae) with special emphasis on characters of the lemma and caryopsis by MIHAI COSTEA and FRANÇOS J. TARDIF—**20(2):**525

Taxonomy of the Polemoniaceae: the subfamilies and tribes by VERNE GRANT—**20(4):**1371

The bracteoles in **Amaranthus** (Amaranthaceae): their morphology, structure, function, and taxonomic significance by MIHAI COSTEA and FRANÇOIS J. TARDIF —**20(3):**969

The east-west transition of the flora in Texas: a biogeographical analysis by MICHAEL H. MACROBERTS and BARBARA R. MACROBERTS—**20(4):**1693

The flora of Oktibbeha County, Mississippi by ANDREAS LEIDOLF, SIDNEY MCDANIEL, and TIM NUTTLE—**20(2):**691

The genus **Campomanesia** (Myrtaceae) in Atlantic rainforest fragments in Sergipe, northeast region of Brazil by MYRNA F. LANDIM and LESLIE R. LANDRUM—**20(1):**205

The genus **Packera** (Asteraceae: Senecioneae) in Colorado, U.S.A. by DEBRA K. TROCK—**20(3):**1023

The identity of eaglewood (**Gyrinops**, Thymelaeaceae), a new economic resource for Papua New Guinea by W. TAKEUCHI and M. GOLMAN—**20(1):**261

The John D. Freeman Herbarium (AUA): a history and catalogue of vascular plant type specimens by CURTIS J. HANSEN—**20(3):**1277

The name of the amaranth: histories of meaning by MIHAI COSTEA and FRANÇOIS J. TARDIF—**20(3):**1073

The present status of Ledermann's April River localities in Papua New Guinea by W. TAKEUCHI and M. GOLMAN—**20(1):**55

The resurrection and lectotypification of **Tetrazygia fadyenii** (Melastomataceae: Miconieae): a hummingbird-pollinated treelet endemic to Jamaica by DARIN S. PENNEYS and WALTER S. JUDD—**20(3):**877

The taxonomy and morphology of **Macranthera flammea** (Orobanchaceae) by JILL D. ALFORD and LORAN C. ANDERSON—**20(1):**189

The varieties of **Liatris elegans** (Asteraceae) by MARK H. MAYFIELD—**20(2):**597

The vascular flora of the Cerrado in Emas National Park (Goiás, central Brazil) by MARCO ANTÔNIO BATALHA and FERNANDO ROBERTO MARTINS—**20(1):**295

The vascular flora of the Laguna de Alegría,

a national monument in the crater of Tecapa Volcano, El Salvador by Denise Williams, Rudys W. Herrera, and José L. Linares—**20(2):**675

The vascular flora of the Ogallala ecotone on the Dempsey Divide, Roger Mills County, Oklahoma by Craig C. Freeman and Caleb A. Morse—**20(3):**1217

Triglochin concinna (Juncaginaceae), a new family, genus, and species for Texas by B.L. Turner and Matt W. Turner—**20(4):**1721

Two new combinations in Bolivian **Gentianella** (Gentianaceae) by James S. Pringle—**20(4):**1485

Two new species of **Festuca** from South America (Poaceae: Loliinae: sect. Subulatae) by Daniel Stančík and Paul M. Peterson—**20(1):**21

Two new species of **Liatris** series **Graminifoliae** (Asteraceae: Eupatorieae) from the southeastern United States by Robert Kral and Guy L. Nesom—**20(4):**1573

Two new species of **Parathesis** (Myrsinaceae) from Mesoamerica and neotypification of **Parathesis rothschuhiana** by Jon M. Ricketson and John J. Pipoly III—**20(3):**899

Two new species of **Weinmannia** (Cunoniaceae: Cunonieae) from southern Ecuador by Zachary S. Rogers—**20(1):**179

Type localities of vascular plants first described from Ohio by Ronald L. Stuckey and James S. Pringle—**20(4):**1677

Typification and nomenclatural history of **Trachelospermum difforme** (Apocynaceae) by Alexander Krings—**20(4):**1641

Typification, taxonomy, and a new subspecies of **Polygonum sawatchense** (Polygonaceae) from North America by Mihai Costea and François J. Tardif—**20(4):**1631

Una especie nueva de **Portulaca** (Portulacaceae) del norte de Michoacán (México) by Gilberto Ocampo Acosta—**20(2):**487

Usos de Melastomataceae en el Ecuador by Alina Freire Fierro, Diana Fernández, and Catalina Quintana—**20(1):**233

Uvularia (Liliaceae) in Texas by Jason R. Singhurst, William F. Carr, Wendy J. Ledbetter, and Walter C. Holmes—**20(4):**1713

Vascular flora of Big Lake Bottom Wildlife Management Area, Anderson County, Texas by Kay M. Fleming, Jason R. Singhurst, and Walter C. Holmes—**20(1):**355

Vascular plants of Konza Prairie Biological Station: an annotated checklist of species in a Kansas tallgrass prairie by E. Gene Towne—**20(1):**269

Vascular plants of the Mapimí Biosphere Reserve, México: a checklist by Abel García-Arévalo—**20(2):**797

West Gulf Coastal Plain ecoregions by Michael H. MacRoberts and Barbara R. MacRoberts—**20(3):**1247

What is the writer of a flora to do? Evolutionary taxonomy or phylogenetic systematics? by George M. Diggs, Jr. and Barney L. Lipscomb—**20(2):**647

William Dean Reese (1928–2002) by Ronald A. Pursell and Paul L. Redfearn—**20(3):**1335

Yucca cernua (Agavaceae: series Rupicolae), a new species from Newton and Jasper counties in eastern Texas by Eric L. Keith—**20(3):**891

INDEX OF 202 AUTHORS: VOLUME 20 (2002-2003)

Thank you for choosing *Sida, Contributions to Botany.*

Index of Botanical Names: Volume 20 (2002–2003)

New names (229) in **bold face**

Abronia—**20(3):**877
umbellata var. **breviflora**—**20(3):**888
Aciotis—**20(1):**234
Acleisanthes—**20(3):**885
lanceolata var. **megaphylla**—**20(3):**886
Agalinis
filicaulis—**20(3):**1321
harperi (Texas record)—**20(3):**1321
nuttallii (Arkansas record)—**20(4):**1739
Agarista boliviensis—**20(1):**4
Agavaceae—**20(1):**349; **20(2):**495
havardiana—**20(2):**498
ovatifolia—**20(2):495,** 496 (illus), 497 (color photos)
parrasana—**20(2):**498
series Rupicolae—**20(3):**891
Agrostis avenacea—**20(1):**423, 424, 425 (illus), 430 (map, color photo, habitat)
Allium stellatum—**20(1):**441
Alstonia scholaris (USA/FL record)—**20(2):**813
Alternanthera
caracasana (Kansas record)—**20(3):**1290
paronychioides—**20(1):**409
Amaranthaceae—**20(3):**969
Amaranth (history)—**20(3):**1073
Amaranthus—**20(3):**969; 1073 (history)
albus—**20(3):**976 (photo, anatomy)
blitoides—**20(3):**976 (photo, anatomy)
blitum
ssp. blitum—**20(3):**976 (photo, anatomy)
ssp. emarginatus—**20(3):**976 (photo, anatomy)
ssp. oleraceus—**20(3):**976 (photo, anatomy)
cruentus—**20(3):**975 (photo, anatomy)
hybridus—**20(3):**975 (photo, anatomy)
hypochondriacus—**20(3):**975 (photo, anatomy)
powellii
ssp. bouchonii—**20(3):**975 (photo, anatomy)
ssp. powellii—**20(3):**975 (photo, anatomy)
retroflexus—**20(3):**975 (photo, anatomy)
spinosus—**20(3):**977 (photo, anatomy)
Anaphalis margaritacea—**20(1):**435
Andropogon
glomeratus var. glaucopsis—**20(4):**1723
ischaemum var. songaricus—**20(1):**415
virginicus—**20(4):**1724
Anethum graveolens—**20(1):**405
Anodendron oblongifolium—**20(1):**59 (plant poison)
Apocynaceae—**20(1):**105
Aquilaria filaria—**20(1):**266
Araceae—**20(2):**819
Arachnis beccarii var. imthurnii—**20(2):**466, 463, (illus), 468 (illus)
Ardisia
escallonioides—**20(3):**909
subgenus Graphardisia—**20(4):**1423, **1424**
nigrescens—**20(4):**1426
subsp. **donnellsmithii**—**20(4):1431,** 1432 (illus)

subsp. nigrescens—**20(4):1428,** 1429 (illus)
tuerckheimii—**20(4):**1437, 1439 (illus)
verdisepala—**20(4):1435,** 1436 (illus)
Arida—**20(4):**1390, **1410**
arizonica—**20(4):**1413
blepharophylla—**20(4):1413,** 1663 (photo, chromosomes)
carnosa—**20(4):**1413
coulteri—**20(4):**1414
crispa—**20(4):**1414
mattturneri—**20(4):**1414, **1418,** 1420–1421 (color photos), 1663 (photo, chromosomes)
parviflora—**20(4):**1414
riparia—**20(4):**1414
turneri—**20(4):1414,** 1419
Arisaema triphyllum (Texas disjunct record)—**20(3):**1327, 1329–1331 (color photos)
Arthrostemma—**20(1):**235
Aster laevis var. purpuratus—**20(1):**437
Asteraceae—**20(1):**145, 149, 176, 71, **9**7; **20(2):**505, 511, 515, 559, 597, 845
Astereae—**20(4):**1387, 1481, 1585, 1589, 1595, 1617
subtribe **Bellidinae**—**20(4):**1649
Coreopsideae—**20(2):**593
Eupatorieae—**20(4):**1573
Senecioneae—**20(2):**605; **20(3):**1023
Astronidium morobiense—**20(4):**1527, 1528–1529 (photo)
Axinaea—**20(1):**235
Azolla caroliniana (Arkansas record)—**20(4):**1740

Baccharis—**20(4):**1481
sect. Aristidentes—**20(4):**1483
sect. Bogotenses—**20(4):**1483
sect. **Punctatae**—**20(4):**1481
sect. Tubulatae—**20(4):**1482
Barringtonia—**20(4):**1527
Bejaria aestuans—**20(1):**4
Bellucia—**20(1):**235
Berberis bealei—**20(2):**815 (Florida record)
Bergia texana—**20(1):**412
Bidens alba var. radiata—**20(1):**438
Blakea—**20(1):**235
Boerhavia
coulteri
var. coulteri—**20(1):**154
var. **palmeri**—**20(1):**151, **153**
spicata—**20(1):**154
torreyana—**20(1):**154
wrightii—**20(1):**154
Boraginaceae—**20(2):**495
Bowlesia incana—**20(1):**410
Brachyotum—**20(1):**236
Brazoria
arenaria—**20(4):**1571
enquistii—**20(4):1565,** 1567–1568 (map), 1569 (color photos)
truncata—**20(4):**1571
Bromelia penguin—**20(2):**814 (USA/FL record)
Bromus nottowayanus—**20(1):**397
Bulbophyllum pachyglossum—**20(2):**474, 476 (illus)
Bulbostylis
barbata—**20(1):**340
pubescens—**20(1):**340

Cactaceae—**20(1):**349; **20(2):**809; **20(3):**1665
Cadetia echinocarpa—**20(2):**474, 477 (illus)
Calanthe triplicata—**20(2):**474, 478 (illus)
Calibrachoa parviflora (Colorado record)—**20(3):**1290

Calycanthus floridus var. glaucus **20(1):**439
Campomanesia —**20(1):**205
aromatica—**20(1):**208
dichotoma—**20(1):**207, 210
guaviroba—**20(1):**208 (illus), 209 (photo), 210
viatoris—**20(1):**207, 208 (illus), 211
Canna glauca (Florida record)—**20(2):**815
Caperonia palustris—**20(1):**412
Caprifoliaceae—**20(2):**849
Carex
albicans var. australis (Kansas record)—**20(3):**1290
buxbaumii—**20(1):**398
conoidea—**20(4):**1727 (Arkansas record)
corrugata—**20(1):**398
oklahomensis—**20(1):**398
ouachitana—**20(1):**398
oxylepis var. pubescens—**20(1):**399
planostachys—**20(1):**340
roanensis—**20(1):**399
seorsa—**20(1):**390
swanii (Kansas record)—**20(3):**1290
thurberi—**20(1):**341
Carphephorus odoratissimus—**20(2):**559, 561 (illus), 565 (map)
Carum carvi (Kansas record)—**20(3):**1291
Caryophyllaceae—**20(1):**227
Castilleja
albobarbata—**20(4):1343,** 1344 (color photos), 1345 (map)
integrifolia—**20(4):**1345 (map)
Catharanthus roseus (Kansas record)—**20(3):**1291
Cavendishia
bracteata—**20(1):**6
martii—**20(1):**6
pubescens—**20(1):**6
Cerastium—**20(1):**227–231 (chromosome numbers)
Chamaesyce prostrate (Colorado record) —**20(3):**1291
Chaptalia
estribensis—**20(4):**1368
hidalogoensis—**20(4):1363,** 1364 (illus), 1368
hintonii—**20(4):**1368
lyratifolia—**20(4):**1368
madrensis—**20(4):**1368
mexicana—**20(4):**1365, 1367 (illus), 1368
pringlei—**20(4):**1368
tomentosa—**20(4):**1368
Cirsium nuttallii—**20(2):**845 (North Carolina record), 847 (b/w photos)
Citrullus lanatus var. lanatus—**20(1):**412
Cladium mariscus—**20(4):**1526
Clidemia—**20(1):**236
Commelina benghalensis (North Carolina record)—**20(1):**419, 420 (illus)
Conostegia—**20(1):**237
Convolvulaceae—**20(1):**39; **20(3):**1351
Corchorus—**20(3):**1299
olitorius—**20(3):**1301, 1302 (map), 1303 (illus)
trilocularis—**20(3):**1302 (map), 1305, 1306 (illus)
Corybas epiphyticus—**20(2):**469, 470 (illus)
Costus pulverulentus (USA/FL record)—**20(2):**814
Crataegus—**20(1):**115
atrovirens—**20(1):141,** 142 (illus)
castlegarensis—**20(1):121,** 122 (illus), 124 (map)
douglasii—**20(1):**120
enderbyensis—**20(1):136,** 137 (illus)

okanaganensis—**20(1):**131
var. **wellsii**—**20(1):132,** 133 (illus), 134 (map)
okennonii—**20(1):**121
orbicularis—**20(1):138,** 140 (illus)
phippsii—**20(1):**143
shuswapensis—**20(1):128,** 129 (illus)
suksdorfii—**20(1):**119
thermopegaea (Arkansas record)—**20(4):**1740
williamsii—**20(1):**131
Cryptocoryne
beckettii—**20(2):**819, 826, 827 (color photos)
undulata—**20(2):**822 (color photo)
wendtii—**20(2):**823, 827 (color photos)
Cryptomeria—**20(3):**999
Cunoniaceae—**20(1):**179
Cuphea viscosissima—**20(1):**442
Cupressaceae—**20(2):**585
Cupressus arizonica—**20(2):**585, **20(3):**1325
Cynoglossum zeylanicum—**20(1):**411
Cynosurus echinatus (Texas record)—**20(2):**837
Cyperaceae—**20(1):**339; **20(3):**1727
Cyperus
arsenei—**20(1):**341
cephalanthus—**20(1):**440
diandrus (Kansas record)—**20(3):**1291
manimae—**20(1):**341
var. asperrimus—**20(1):**341
var. divergens—**20(1):**341
var. manimae—**20(1):**342
sphaerolepis—**20(1):**342
Cyrtomium falcatum (Arkansas record)—**20(4):**1740

Dahlia **neglecta**—**20(2):593,** 595 (illus)
Demosthenesia
mandonii—**20(1):**8
pearcei—**20(1):**8
spectabilis—**20(1):**8
Dendrobium
antennatum—**20(2):**467 (illus)
archipelagense—**20(2):464,** 465 (illus), 467 (illus)
cuthbertsonii—**20(2):**479, 480 (illus)
gnomus—**20(2):**469, 471 (illus)
masarangense—**20(2):**479, 481 (illus)
rhodostictum—**20(2):**479, 482 (illus)
strepsiceros—**20(2):**467 (illus)
vexillarius var. **hansmeyerense**—**20(2):462,** 463 (illus)
Deschampsia danthonioides (Iowa record)—**20(3):**1291
Dichanthelium—**20(1):**161
aciculare
subsp. **angustifolium**—**20(1):**167
subsp. **fusiforme**—**20(1):**167

Guidelines: http://www.brit.org/Sida/SubmitPaper.htm

Sida, Contributions to Botany is an international journal of systematic botany containing primary research papers sensu lato, including anatomy, biogeography, chemotaxonomy, cladistics, ecology, floristics, genetics & evolution, numerical taxonomy, paleobotany, and palynology. **Sida** is open to all authors anywhere; coverage is not restricted to any geographical area.

All manuscripts submitted to **Sida** are considered by at least two reviewers. Manuscripts may be submitted in English or Spanish. Page costs are $35 per page but may be waived or reduced under certain circumstances. Please contact the editor and make arrangements before publication. Manuscripts are not rejected due to lack of financial support. Submit manuscripts and editorial questions to Barney Lipscomb, Botanical Research Institute of Texas, 509 Pecan Street, Fort Worth, TEXAS 76102-4060, U.S.A. Phones: 1-817-332-4441 voice; 1-817-332-4112 fax. Our electronic mail address is sida@brit.org. Access our **Sida** home page at the URL *http://www.brit.org/sida/*

Please submit manuscripts in electronic format as an email attachment. If you wish submissions are also accepted by USPS mail with a single hard copy and on computer disk. Figures/illustrations may be submitted in low-resolution format (**jpgs**) as email attachments for review purposes only. Upon acceptance for publication, the manuscript may be submitted as an email attachment or returned in the mail with a single hard copy and an electronic copy. If you have figures/illustrations in electronic format they should be submitted in **tif** format, scanned at the absolute best quality possible. Digital figures may have to be submitted on a CD-ROM disk if they are too large for email. Typically b/w line drawings should be scanned at 600 dpi or higher and b/w half tones and color photos at 300 dpi. If you need your figures/illustrations digitized, the editorial staff at **Sida** will be happy handle any electronic digitization needs you have; all original material can be returned if requested. Color digitization works best from color transparencies (slides).

Consult the latest issue of **Sida** for format of articles and notes regarding title, author, and address. Ranges of numbers are separated by double hyphens (6--8) OR use an en dash. Footnotes, figure legends, appendices, and tables should be on separate pages and inserted at end of manuscript following references. Authors are encouraged to use the APG families, nearly all of which are on /APweb/ which can be accessed through the Missouri Botanical Garden research site (Angiosperm phylogeny).

ABSTRACT

Every paper should include both an English and Spanish, or another major language abstract.

SPECIMEN CITATIONS

Use the collector's last name and number or (s.n) and underline. Abbreviate the months of the year by the first three letters of the month without a period. Example: Texas. Jeff Davis Co.: 1 mi W of Fort Davis, 3 Jan 1972, Smith 118 (BRIT).

AUTHOR CITATIONS

Use the author abbreviations as given in the *Author Abbreviations* compiled at the Herbarium, Royal Botanic Gardens, Kew (1992). Use et or the ampersand (&) between two authors; for more than two authors, restrict to the first one followed by et al. Do not *italicize* or underline in the manuscript the terms et, et al., ex, or in.

LATIN DESCRIPTIONS OR DIAGNOSES; ENGLISH DESCRIPTIONS

Please provide a Latin diagnosis for each new taxon. After the Latin diagnosis, an English or Spanish version is recommended highlighting the diagnostic characters. Write plant descriptions as incomplete sentences with phrases separated by semicolons.

FIGURES

Please present ALL figures (maps included) as a unified, single sequence of figures. A scale should be in or on the illustration or photograph; reduction will automatically reduce the scale and subject proportionately. In halftones, sharp glossy photographs with good contrast are necessary for good reproduction. Please mount illustrative material (halftones, line drawings, etc.) on flexible paper so that may be mounted and on a high-speed drum scanner if need. You may also submit graphic materials in electronic format. Typically b/w line drawings should be scanned at 600 dpi or higher and b/w half tones and color photos at 300 dpi. Please consult the editor for additional information if need. Color figures can be used and an additional cost maybe charged. Color digitization works best from color transparencies (slides). Please submit color prints for reviewing purposes.

REFERENCES

This includes all of the literature cited in the text and may include other article citations the author may deem desirable. Normal text references should be cited

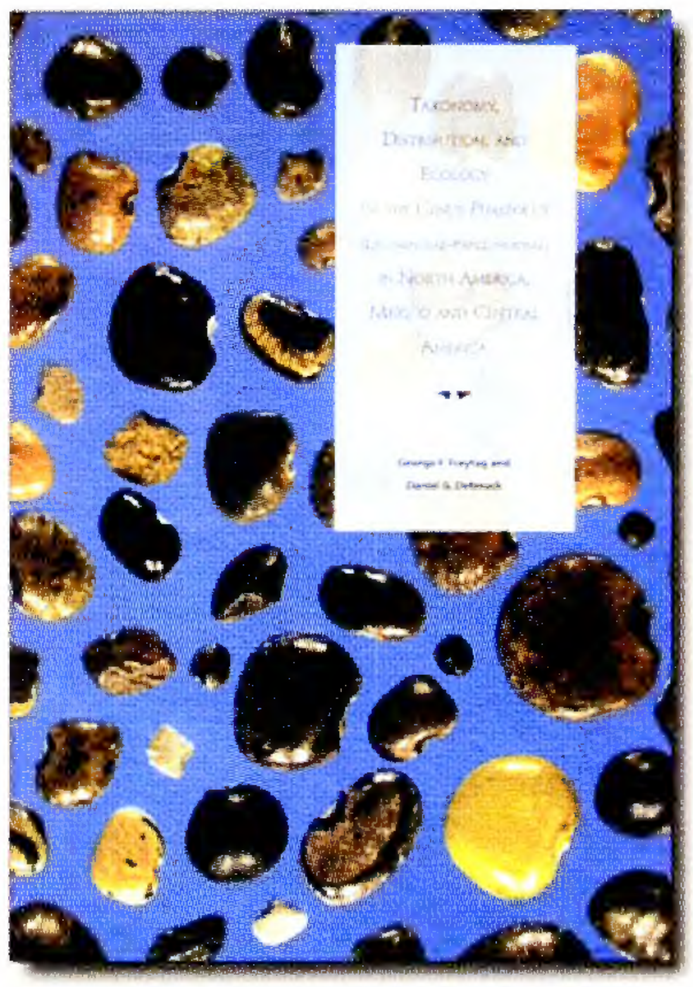
as follows: 'Ricketson and Pipoly (1997) stated ...' or 'the latest revision (Ricketson & Pipoly 1997)' when reference is used as authority for a statement. When there are three or more authors use only the name of the first author followed by et al.: 'Barrie et al. (1992a) stated'. References at the end of the article are arranged alphabetically and chronologically making use of a,b, etc. if an author had more than one publication in a given year. Author's names are printed in Cap/small caps, NOT ALL CAPS; please type author names in Cap/small cap or in Cap/lower case except for initial capitals. Only the first letter of the initial word, proper nouns, and proper adjectives of titles should be capitalized. Please note there is no space between initials of authors. For journal abbreviations, use *Botanico-Periodicum-Huntianum*. Reference examples:

Barrie, F.R., C.E. Jarvis, and J.L. Reveal. 1992a. The need to change Article 8.3 of the Code. Taxon 41:508—512.

Ricketson, J. and J. Pipoly. 1997. A synopsis of the genus *Gentlea* (Myrsinaceae) and a key to the genera of Myrsinaceae in Mesoamerica. Sida 17:697—707. [author's names in cap/lower case]

Crawford, D.J. 1983. Phylogenetic and systematic inferences from electrophoretic studies. In: S.D. Tanksley and T.J. Orton, eds. Isozymes in plant genetics and breeding, Part A. Elsevier, Amsterdam. Pp. 257—287. [author's names in cap/small cap]

Sivinski, R.C. and K. Lightfoot (eds.). 1995. Inventory of rare and endangered plants of New Mexico. New Mexico Forestry and Resources Conservation Division. Energy, Minerals and Natural Resources Department. Misc. Pub. No. 4.



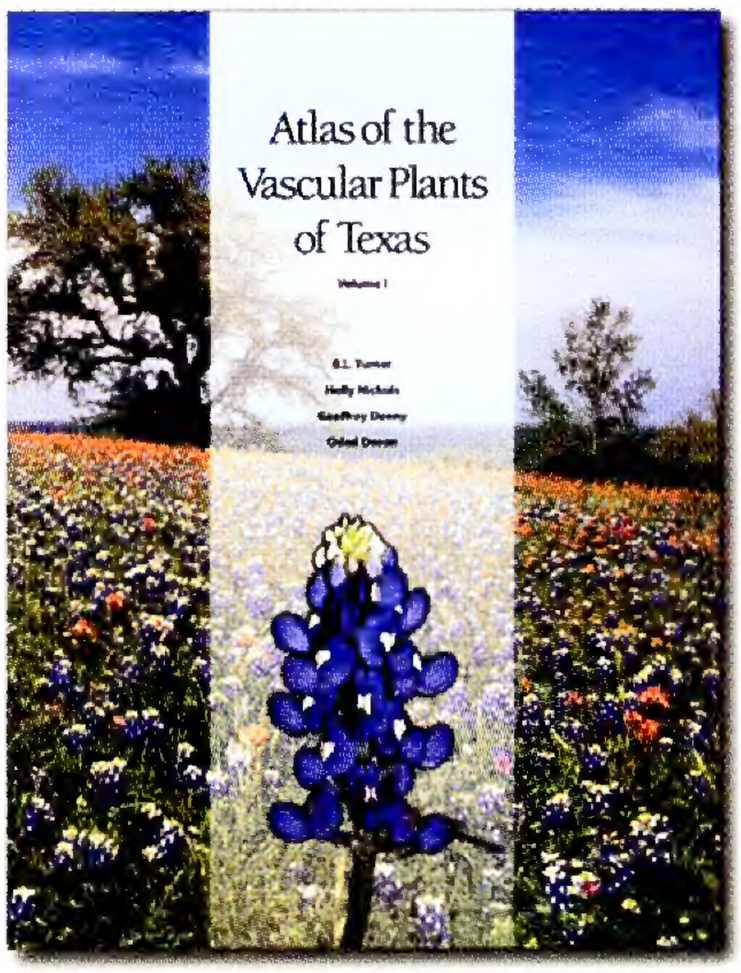
ABBREVIATIONS

When the following abbreviations are used the period is omitted. Distance: mm, dm, cm, m, km, ft, mi; directions (in caps): S, N, E, W, months: first 3 letters only, Jan, Feb, etc. Example: Potter Co.: 2 km W of Dot, 5 Jun 1971, Smith 118 (SMU).

DOCUMENTED PLANT CHROMOSOME NUMBERS

Refer to **Sida** 20(4):1663. 2003.

This lavishly illustrated monograph is the most comprehensive botanical treatment of beans to date. It begins with a brief history about the former taxonomical treatments of the genus, and goes on with the taxonomical criteria and a presentation about discriminant characteristics. It presents a full description of each section and species, its distribution and habitat, relationships with other species, uses and potentially useful traits, and historical notes. Color pictures, line drawings, and distribution maps lead easily to the right identification of each species.



Taxonomy, Distribution, and Ecology of the Genus Phaseolus (Leguminosae–Papilionoideae) in North America, Mexico and Central America

The *Atlas of Texas* covers about 6000 taxa. This is the result of 54 years of herbarium and fieldwork by B.L. Turner, beginning in 1948 at Sul Ross State University, Alpine, Texas. In short, the senior author has examined personally, touched, or "pored over" an estimated several hundred thousand sheets in the preparation of the forthcoming Atlas volumes. Contents include an introduction, atlas of Texas plants arranged alphabetically by family, by genus, by species, and an index.
